    if (cc != 2) return FALSE;
    return TRUE;
}
```

Grammar Verbs 13/gv

Purpose

A grammar verb is not literally a verb, as the name is a hangover from the way I6 defines grammar. It might be said to be a necklace onto which we thread the sea-shells of grammar lines. Each grammar verb has its own purpose: to match various possibilities (one for each grammar line) against text aimed at a particular result. For instance, all run time commands beginning with TAKE are parsed with a single grammar verb. If we create a new grammar token, "[polite remark]", for use in other grammar, then that too will have its own "grammar verb". If we define the word "eleventy-one" as meaning the number 111, it will be added to a grammar verb attached to the data type `NUMBER` which parses eccentric names for number values. And so on. Probably a better name for this structure would be simply "grammar", but that might be confusing in other ways, and anyway the ship has sailed.

13/gv.§2-8 Command words; §9-10 Named grammar tokens; §11 Consultation grammars; §12 Object parsing grammars; §13 Data type parsing grammars; §14 Property name parsing grammars; §15-18 The list of grammar lines; §19 Grammar Preparation; §20 Phase I: Slash Grammar; §21 Phase II: Determining Grammar; §22-26 Phases III and IV: Sort and Compile Grammar

---

Template interpreter commands

```
18  {-callv:compile_grammar_conditions}
19  {-callv:prepare_grammar}
22  {-callv:compile_grammar_verbs}
```

Definitions

¶1. There are five different sorts of grammar verb, then, and only the first of these is associated with a genuine typed-by-the-player command verb:

```
define GV_IS_COMMAND 1                  an imperative verbal command at run-time
define GV_IS_TOKEN   2                  a square-bracketed token in other grammar
define GV_IS_OBJECT  3                  a noun phrase at run time: a name for an object
define GV_IS_VALUE   4                  a noun phrase at run time: a name for a value
define GV_IS_CONSULT 5                  a pattern to match in part of a command (such as "consult")
define GV_IS_PROPERTY_NAME 6            a noun phrase at run time: a name for an either/or pval
```

¶2. The following maxima are imposed by the I6 compiler:

```
define MAX_ALIASED_COMMANDS 32
define MAX_LINES_PER_COMMAND 32

typedef struct grammar_verb {
    int gv_is;                                          one of the five values above
    struct grammar_type gv_type;
    struct grammar_line *first_line;                    linked list in creation order
    struct grammar_line *sorted_first_line;             and in logical applicability order
    int command_wn;                                     GV_IS_COMMAND: word number at which command found
    int aliased_command_wn[MAX_ALIASED_COMMANDS];       ...and other commands synonymous
    int no_aliased_commands;                            ...and how many of them there are
    int word_ref1, word_ref2;                           GV_IS_TOKEN: name of this token
    struct world_object *wo_understood;                 GV_IS_OBJECT: what this provides names for
    struct kind_of_value *kov_understood;               GV_IS_VALUE: for which type it names an instance of
    struct property_name *prn_understood;               GV_IS_PROPERTY_NAME: which prn this names
    struct parse_node *where_gv_created;                for problem message reports
    char gv_I6_identifier[32];                          when a token is delegated to an I6 routine
    MEMORY_MANAGEMENT
} grammar_verb;
int no_verb_verb_defined = FALSE;
```

The structure grammar_verb is private to this section.

¶3. A few imperative verbs are reserved for Inform testing, such as SHOWME. We record those as instances of the following:

```
typedef struct reserved_command_verb {
    char reserved_text[32];
    MEMORY_MANAGEMENT
} reserved_command_verb;
```

The structure reserved_command_verb is private to this section.

---

§**1.** We begin as usual with a constructor and some debug log tracing.

```
grammar_verb *gv_new(int gv_is) {
    grammar_verb *gv;
    gv = CREATE(grammar_verb);
    gv->command_wn = -1;
    gv->first_line = NULL;
    gv->gv_type = gty_new(FALSE);
    gv->gv_is = gv_is;
    gv->word_ref1 = -1; gv->word_ref2 = -1;
    gv->no_aliased_commands = 0;
    gv->sorted_first_line = NULL;
    gv->kov_understood = NULL;
    gv->prn_understood = NULL;
    gv->where_gv_created = current_sentence;
    gv->gv_I6_identifier[0] = 0;
```

```
    return gv;
}
void log_grammar_verb(grammar_verb *gv) {
    LOG("<GV%d:", gv->allocation_id);
    switch(gv->gv_is) {
        case GV_IS_COMMAND:
            if (gv->command_wn == -1) LOG("command=no-verb verb");
            else LOG("command=$W", gv->command_wn, gv->command_wn);
            break;
        case GV_IS_TOKEN: LOG("token=$W", gv->word_ref1, gv->word_ref2); break;
        case GV_IS_OBJECT: LOG("object"); break;
        case GV_IS_VALUE: LOG("value=$u", gv->kov_understood); break;
        case GV_IS_CONSULT: LOG("consult"); break;
        case GV_IS_PROPERTY_NAME: LOG("property-name"); break;
        default: LOG("<unknown>"); break;
    }
    LOG(">");
}
```

The function log_grammar_verb is called from 2/dl.

§2. **Command words.** Some GVs are used to represent the command grammar for imperative verbs used by the player at run-time. Such a GV handles multiple commands, which are considered equivalent at run-time: the first of these is the official command word, and the rest are "aliases". For instance, the Standard Rules create a GV for the command PULL with one alias, DRAG. (This somewhat asymmetric approach is used because it matches the way I6 `Verb` declarations are laid out.)

A complication is that one GV is permitted to be a special case: the so-called "no verb verb", whose main command word is empty and which can have no aliases. This is used to parse verbless commands at run-time: for instance, the I7 designer can specify that a command consisting only of a number followed by the word GO should cause some action, and this is implemented not with a command verb but using I6's hooks for verbless commands. The grammar "[number] go" is attached as a grammar line to the "no verb verb", which is distinguished by having its command word number set to `-1`. Note that the "no verb verb" exists only in runs of NI where it has been needed: the Standard Rules do not use it.

Command GVs other than the "no verb verb" are said to be "genuinely verbal".

```
int gv_get_verb_wn(grammar_verb *gv) {
    return gv->command_wn;
}
int gv_is_genuinely_verbal(grammar_verb *gv) {
    if ((gv->gv_is == GV_IS_COMMAND) && (gv->command_wn != -1))
        return TRUE;
    return FALSE;
}
```

The function gv_get_verb_wn is called from 13/gl.

§**3.** The next routine finds, or if necessary creates, a GV for a given command word encountered without any indication that it should alias another. Note that calling this with word number `-1` finds, or creates, the "no verb verb".

```
grammar_verb *gv_find_or_create_command(int vw) {
    grammar_verb *gv = gv_find_command(vw);
    if (gv) return gv;
    gv = gv_new(GV_IS_COMMAND);
    gv->command_wn = vw;
    if (vw == -1) no_verb_verb_defined = TRUE;
    else {
        LOGIF(GRAMMAR_CONSTRUCTION, "GV%d has verb %d = <%s>\n",
            gv->allocation_id, vw, lw_array[vw].lw_text);
    }
    return gv;
}
```

The function gv_find_or_create_command is called from 13/tfg.

§**4.** By contrast, this routine merely finds a GV, or returns null if none exists with the given command word.

```
grammar_verb *gv_find_command(int vw) {
    grammar_verb *gv;
    LOOP_OVER(gv, grammar_verb)
        if (gv->gv_is == GV_IS_COMMAND) {
            int i;
            if (vw == -1) {
                if (gv->command_wn == -1) return gv;
            } else {
                if (compare_words(vw, gv->command_wn)) return gv;
                for (i=0; i<gv->no_aliased_commands; i++)
                    if (compare_words(vw, gv->aliased_command_wn[i])) return gv;
            }
        }
    return NULL;
}
```

The function gv_find_command is called from 13/tfg.

§**5.** We now have routines to add or remove commands from a given GV. Removing is the tricky case, since detaching the main command word means that one of the aliases must become the new main command; or, in the worst case, that there are no commands left, in which case we need to empty the GV of grammar lines so that it can either be ignored or re-used (in the event that the designer, having cancelled the old meaning of the command, now supplies new ones).

It is not possible to add to, or remove from, the "no verb verb".

```
void gv_add_command(grammar_verb *gv, int wn) {
    if (gv == NULL)
        internal_error("tried to add alias command to null GV");
    if (gv->gv_is != GV_IS_COMMAND)
        internal_error("tried to add alias command to non-command GV");
    if (gv->no_aliased_commands == MAX_ALIASED_COMMANDS) {
        sentence_problem(_P_(C13TooManyAliases),
            "this 'understand the command ... as ...' makes too many aliases "
            "for the same command",
            "exceeding the limit of 32.");
        return;
    }
    gv->aliased_command_wn[gv->no_aliased_commands++] = wn;
    LOGIF(GRAMMAR, "Adding alias '%s' (%d) to G%d '%s' (%d)\n",
        lw_array[wn].lw_text, wn, gv->allocation_id, lw_array[gv->command_wn].lw_text, gv->command_wn);
}
void gv_remove_command(grammar_verb *gv, int wn) {
    if (gv == NULL)
        internal_error("tried to detach alias command from null GV");
    if (gv->gv_is != GV_IS_COMMAND)
        internal_error("tried to detach alias command from non-command GV");
    LOGIF(GRAMMAR, "Detaching verb '%s' from grammar\n", lw_array[wn].lw_text);
    if (gv == NULL) return;
    if (compare_words(gv->command_wn, wn)) {
        LOGIF(GRAMMAR, "Detached verb is the head-verb\n");
        if (gv->no_aliased_commands == 0) {
            gv->first_line = NULL;
            LOGIF(GRAMMAR, "Which had no aliases: clearing grammar to NULL\n");
        } else {
            gv->command_wn = gv->aliased_command_wn[--(gv->no_aliased_commands)];
            LOGIF(GRAMMAR, "Which had aliases: making new head-verb '%s'\n",
                lw_array[gv->command_wn].lw_text);
        }
    } else {
        LOGIF(GRAMMAR, "Detached verb is one of the aliases\n");
        int i, j;
        for (i=0; i<gv->no_aliased_commands; i++) {
            if (compare_words(gv->aliased_command_wn[i], wn)) {
                for (j=i; j<gv->no_aliased_commands-1; j++)
                    gv->aliased_command_wn[j] = gv->aliased_command_wn[j+1];
                gv->no_aliased_commands--;
                break;
            }
        }
    }
}
```

The function gv_add_command is called from 13/tfg.
The function gv_remove_command is called from 13/tfg.

§**6.** Command GVs are destined to be compiled into `Verb` directives, as follows.

```
void gv_compile_Verb_directive_header(OUTPUT_STREAM, grammar_verb *gv) {
    if (gv->gv_is != GV_IS_COMMAND)
        internal_error("tried to compile Verb from non-command GV");
    if (gv->first_line == NULL)
        internal_error("compiling Verb for empty grammar");
    if (gv->command_wn == -1)
        WRITE("Verb 'no.verb'");
    else {
        int i;
        WRITE("Verb ");
        if (command_verb_reserved(lw_array[gv->command_wn].lw_text)) {
            current_sentence = gv->where_gv_created;
            quote_source(1, current_sentence);
            quote_text(2, lw_array[gv->command_wn].lw_text);
            handmade_problem(_P_(C13ReservedVerb));
            issue_problem_segment(
                "You wrote %1, but %2 is a built-in Inform testing verb, which "
                "means it is reserved for Inform's own use and can't be used "
                "for ordinary play purposes. %PThe verbs which are reserved in "
                "this way are all listed in the alphabetical catalogue on the "
                "Actions Index page.");
            issue_problem_end();
        }
        isn_compile_dictionary_word(OUT, lw_array[gv->command_wn].lw_text, FALSE);
        for (i=0; i<gv->no_aliased_commands; i++) {
            WRITE(" ");
            isn_compile_dictionary_word(OUT, lw_array[gv->aliased_command_wn[i]].lw_text, FALSE);
        }
    }
    WRITE("\n");
}
```

§**7.** Reserved verb names are collated as the I6 template files are read:

```
void reserve_command_verb(char *verb_name) {
    reserved_command_verb *rcv = CREATE(reserved_command_verb);
    normalise_cv_to(verb_name, rcv->reserved_text);
    index_test_verb(rcv->reserved_text);
}
int command_verb_reserved(char *verb_tried) {
    reserved_command_verb *rcv;
    char normalised_vt[32];
    normalise_cv_to(verb_tried, normalised_vt);
    LOOP_OVER(rcv, reserved_command_verb)
        if (strcmp(normalised_vt, rcv->reserved_text) == 0)
            return TRUE;
    return FALSE;
}
void normalise_cv_to(char *from, char *to) {
    int i;
    for (i=0; (i<31) && (from[i]); i++) to[i] = tolower(from[i]);
    to[i] = 0;
}
```

The function reserve_command_verb is called from 14/i6t.

§**8.** The "Commands available to the player" portion of the Actions index page is, in effect, an alphabetised merge of the GLs found within the command GVs. GLs for the "no verb verb" appear under the special headword "0" (which is not displayed); otherwise GLs appear under the main command word, and aliases are shown with references like: "drag", same as "pull".

One routine takes a GV and creates suitable entries for the Actions index to process; the other two routines act upon any such entries once they are needed.

```
void gv_make_command_index_entries(grammar_verb *gv) {
    if ((gv->gv_is == GV_IS_COMMAND) && (gv->first_line)) {
        int i;
        if (gv->command_wn == -1)
            vie_new_from("0", gv, NORMAL_COMMAND);
        else
            vie_new_from(lw_array[gv->command_wn].lw_text, gv, NORMAL_COMMAND);
        for (i=0; i<gv->no_aliased_commands; i++)
            vie_new_from(lw_array[gv->aliased_command_wn[i]].lw_text, gv, ALIAS_COMMAND);
    }
}
void gv_index_normal(grammar_verb *gv, char *headword) {
    gl_sorted_list_index_normal(gv->sorted_first_line, headword);
}
void gv_index_alias(grammar_verb *gv, char *headword) {
    if (gv_is_uncensored(gv)) {
        INDEX("&quot;%s&quot;, <i>same as</i> &quot;%s&quot;",
            headword, lw_array[gv->command_wn].lw_text);
        index_below_link(lw_array[gv->command_wn].lw_text);
        INDEX("<br>");
    }
}
```

The function gv_make_command_index_entries is called from 11/ina.
The function gv_index_normal is called from 11/ina.
The function gv_index_alias is called from 11/ina.

§**9. Named grammar tokens.** These are like text substitutions in reverse. For instance, we could define a token "[suitable colour]". These are identified solely by their textual names (e.g., "suitable colour").

```
grammar_verb *gv_named_token_new(int w1, int w2) {
    grammar_verb *gv;
    LOOP_OVER(gv, grammar_verb) {
        if ((gv->gv_is == GV_IS_TOKEN) &&
            (compare_word_range(w1, w2, gv->word_ref1, gv->word_ref2)))
            return gv;
    }
    gv = gv_new(GV_IS_TOKEN);
    gv->word_ref1 = w1; gv->word_ref2 = w2;
    return gv;
}
grammar_verb *gv_named_token_by_name(int w1, int w2) {
    grammar_verb *gv;
    LOOP_OVER(gv, grammar_verb) {
        if ((gv->gv_is == GV_IS_TOKEN) &&
            (compare_word_range(w1, w2, gv->word_ref1, gv->word_ref2)))
            return gv;
    }
    return NULL;
}
```

The function gv_named_token_new is called from 13/tfg.
The function gv_named_token_by_name is called from 13/gtok.

§**10.** A slight variation is provided by those which are defined by I6 routines.

```
void gv_translates(parse_node *pn) {
    parse_node *p1 = pn->down->next;
    parse_node *p2 = pn->down->next->next;
    int w1 = p1->word_ref1, w2 = p1->word_ref2;
    grammar_verb *gv;
    LOOP_OVER(gv, grammar_verb)
        if ((gv->gv_is == GV_IS_TOKEN) &&
            (compare_word_range(w1, w2, gv->word_ref1, gv->word_ref2))) {
                sentence_problem(_P_(C13GrammarTranslatedAlready),
                    "this grammar token has already been translated",
                    "so there must be some duplication somewhere.");
                return;
            }
    gv = gv_named_token_new(w1, w2);
    strcpy(gv->gv_I6_identifier, lw_array[p2->word_ref1].lw_text);
}
void gv_compile_i6_token(OUTPUT_STREAM, grammar_verb *gv) {
    char *n = gv->gv_I6_identifier;
    if (n[0]) WRITE("%s", n);
    else WRITE("GPR_Line_%d", gv->allocation_id);
}
```

The function gv_translates is called from 2/isn.
The function gv_compile_i6_token is called from 13/gtok.

§11. **Consultation grammars.** These are used for grammar included as a column of a table or in a conditional match. The terminology goes back to the early days of I6, when CONSULT was a command capable of parsing arbitrary text, something which a game called Curses made heavy use of.

```
grammar_verb *gv_consultation_new(void) {
    grammar_verb *gv;
    gv = gv_new(GV_IS_CONSULT);
    return gv;
}
```

The function gv_consultation_new is called from 13/gpr.

§12. **Object parsing grammars.** Each world object can optionally have a GV, used to parse unusual forms of its name. The following routine finds or creates this for a given WO.

```
grammar_verb *gv_for_object(world_object *wo) {
    grammar_verb *gv;
    if (wo->understand_as_this_object != NULL)
        return wo->understand_as_this_object;
    gv = gv_new(GV_IS_OBJECT);
    wo->understand_as_this_object = gv;
    gv->wo_understood = wo;
    return gv;
}
void gv_take_out_one_word_grammar(OUTPUT_STREAM, grammar_verb *gv) {
    if (gv->gv_is != GV_IS_OBJECT)
        internal_error("One-word optimisation applies only to objects");
    gv->first_line = gl_list_take_out_one_word_grammar(OUT, gv->first_line);
}
```

The function gv_for_object is called from 13/tfg.
The function gv_take_out_one_word_grammar is called from 9/cot.

§13. **Data type parsing grammars.** Each data type can optionally have a GV, used to parse unusual forms of its literals. The following routine finds or creates this for a given data type.

```
grammar_verb *gv_for_kov(kind_of_value *kov) {
    grammar_verb *gv;
    if (kov_get_parsing_grammar(kov) != NULL)
        return kov_get_parsing_grammar(kov);
    gv = gv_new(GV_IS_VALUE);
    kov_set_parsing_grammar(kov, gv);
    gv->kov_understood = kov;
    return gv;
}
```

The function gv_for_kov is called from 13/tfg.

§**14. Property name parsing grammars.** Only either/or properties can have a GV, used to parse unusual forms of the alternatives as used when properties are describing objects. The following routine finds or creates this for a given property.

```
grammar_verb *gv_for_prn(property_name *prn) {
    grammar_verb *gv;
    if (prn_get_parsing_grammar(prn) != NULL)
        return prn_get_parsing_grammar(prn);
    gv = gv_new(GV_IS_PROPERTY_NAME);
    prn_set_parsing_grammar(prn, gv);
    gv->prn_understood = prn;
    return gv;
}
```

The function gv_for_prn is called from 13/tfg.

§**15. The list of grammar lines.** Every GV has a list of GLs: indeed, this list is really the grammar. Here we test this for emptiness, and provide for adding to it. Removals are not possible.

```
int gv_is_empty(grammar_verb *gv) {
    if ((gv == NULL) || (gv->first_line == NULL)) return TRUE;
    return FALSE;
}
void gv_add_line(grammar_verb *gv, grammar_line *gl) {
    LOGIF(GRAMMAR, "Adding grammar line $g to verb $G\n", gl, gv);
    if ((gv->gv_is == GV_IS_COMMAND) &&
        (gl_list_length(gv->first_line) >= MAX_LINES_PER_COMMAND)) {
        sentence_problem(_P_(C13TooManyGrammarLines),
            "this command verb now has too many Understand possibilities",
            "that is, there are too many 'Understand \"whatever ...\" as ...' "
            "which share the same initial word 'whatever'. The best way to "
            "get around this is to try to consolidate some of those lines "
            "together, perhaps by using slashes to combine alternative "
            "wordings, or by defining new grammar tokens [in square brackets].");
        return;
    }
    gv->first_line = gl_list_add(gv->first_line, gl);
}
```

The function gv_is_empty is called from 13/tfg and 13/gpr.
The function gv_add_line is called from 13/tfg.

§**16.** A censored GV is one which should not appear in the Index because it contains naughty words, in the opinion of the Standard Rules.

```
int gv_is_uncensored(grammar_verb *gv) {
    return gl_line_list_is_uncensored(gv->first_line);
}
```

§**17.** Each GV has the potential to carry a data type made up of the number of values produced, and what their types are. This is only really meaningful for the GVs trying to express a single value: the following routine returns `UNKNOWN` unless that's the case.

```
kind_of_value *gv_get_data_type_as_token(grammar_verb *gv) {
    return gty_get_data_type_as_token(&(gv->gv_type));
}
```

The function gv_get_data_type_as_token is called from 13/gtok.

§**18.** Some tokens require suitable I6 routines to have already been compiled, if they are to work nicely: the following routine goes through the tokens by exploring each GV in turn.

```
void compile_grammar_conditions(OUTPUT_STREAM) {
    grammar_verb *gv;
    LOOP_OVER(gv, grammar_verb) {
        current_sentence = gv->where_gv_created;
        gl_line_list_compile_condition_tokens(OUT, gv->first_line);
    }
}
```

The function compile_grammar_conditions is invoked by a command in a `.i6t` template file.

§**19. Grammar Preparation.** This simply causes Phases I and II of grammar processing to take place, one after the other.

```
void prepare_grammar(void) {
    gv_slash_all();
    gv_determine_all();
}
```

The function prepare_grammar is invoked by a command in a `.i6t` template file.

§**20. Phase I: Slash Grammar.** Slashing is really a grammar-line based activity, so we do no more than pass the buck down to the list of grammar lines.

```
void gv_slash_all(void) {
    grammar_verb *gv;
    log_new_stage_of_NIs_run("Slashing grammar (G1)");
    LOOP_OVER(gv, grammar_verb) {
        LOGIF(GRAMMAR_CONSTRUCTION, "Slashing $G\n", gv);
        gl_line_list_slash(gv->first_line);
    }
}
```

§21. Phase II: Determining Grammar. Again, at this top level we are really only calling downwards.

```
void gv_determine_all(void) {
    grammar_verb *gv;
    log_new_stage_of_NIs_run("Determining grammar (G2)");
    LOOP_OVER(gv, grammar_verb)
        if (gv->first_line) {
            current_sentence = gv->where_gv_created;
            gv_determine(gv, 0);
        }
}

specification *gv_determine(grammar_verb *gv, int depth) {
    specification *spec_union = NULL;
    current_sentence = gv->where_gv_created;
    if (gty_has_return_type(&(gv->gv_type)))
        return gty_get_single_type(&(gv->gv_type));
    if (depth > NUMBER_CREATED(grammar_verb)) {
        sentence_problem(_P_(C13GrammarIllFounded),
            "grammar tokens are not allowed to be defined in terms of "
            "themselves",
            "either directly or indirectly.");
        return NULL;
    }
    LOGIF(GRAMMAR_CONSTRUCTION, "Determining $G\n", gv);
    spec_union = gl_line_list_determine(gv->first_line, depth,
        gv->gv_is, gv, gv_is_genuinely_verbal(gv));
    LOGIF(GRAMMAR_CONSTRUCTION, "Result of verb $G is $S\n", gv, spec_union);
    gty_set_single_type(&(gv->gv_type), spec_union);
    return spec_union;
}
```

The function gv_determine is called from 13/gtok.

§22. Phases III and IV: Sort and Compile Grammar. At this highest level phases III and IV are intermingled, in that Phase III always precedes Phase IV for any given list of grammar lines, but each GV goes through both Phase III and IV before the next begins Phase III. So it would not be appropriate to print banners like "Phase III begins here" in the debugging log.

Finally, though, some substantive work to do: because it is the GV which records the purpose of the grammar in question, we must compile a suitable I6 context for the grammar to appear within.

Four of the five kinds of GV are compiled by the routine below: the fifth kind is compiled in "Tokens Parsing Values", in response to different `.i6t` commands, because the token routines are needed at a different position in the final I6 output.

Sequence is important here: in particular the GPRs must exist before the `Verb` directives, because otherwise I6 will throw not-declared-yet errors.

```
void compile_grammar_verbs(OUTPUT_STREAM) {
    grammar_verb *gv;
    log_new_stage_of_NIs_run("Sorting and compiling non-value grammar (G3, G4)");
    LOOP_OVER(gv, grammar_verb)
        if (gv->gv_is == GV_IS_TOKEN)
            gv_compile(OUT, gv);                    makes GPRs for designed tokens
```

```
    LOOP_OVER(gv, grammar_verb)
        if (gv->gv_is == GV_IS_COMMAND)
            gv_compile(OUT, gv);                                    makes Verb directives
    LOOP_OVER(gv, grammar_verb)
        if (gv->gv_is == GV_IS_OBJECT)
            gv_compile(OUT, gv);                                    makes routines for use in parse_name
    LOOP_OVER(gv, grammar_verb)
        if (gv->gv_is == GV_IS_CONSULT)
            gv_compile(OUT, gv);                                    routines to parse snippets, used as values
    LOOP_OVER(gv, grammar_verb)
        if (gv->gv_is == GV_IS_PROPERTY_NAME)
            gv_compile(OUT, gv);                                    makes routines for use in parse_name
}
```

The function compile_grammar_verbs is invoked by a command in a `.i6t` template file.

§**23.** The following routine unites, so far as possible, the different forms of GV by compiling each of them as a sandwich: top slice, filling, bottom slice. The interesting case is of a GV representing names for an object: the name-behaviour needs to be inherited from the object's kind, and so on up the kinds hierarchy, but this is a case where I7's kind hierarchy does not agree with I6's class hierarchy. I6 has no (nice) way to inherit `parse_name` behaviour from a class to an instance. So we will simply pile up extra fillings into the sandwich. The order of these is important: by getting in first, grammar for the instance takes priority; its immediate kind has next priority, and so on up the hierarchy.

```
void gv_compile(OUTPUT_STREAM, grammar_verb *gv) {
    if (gv->first_line == NULL) return;
    LOGIF(GRAMMAR, "Compiling grammar verb $G\n", gv);
    current_sentence = gv->where_gv_created;
    gl_reset_labels();
    switch(gv->gv_is) {
        case GV_IS_COMMAND:
            gv_compile_Verb_directive_header(OUT, gv);
            break;
        case GV_IS_TOKEN:
            gpr_compile_gpr_head(OUT, gv->allocation_id);
            break;
        case GV_IS_CONSULT:
            gpr_compile_consult_head(OUT, gv->allocation_id);
            break;
        case GV_IS_OBJECT:
            gpr_compile_parse_name_head(OUT, gv->wo_understood, gv);
            break;
        case GV_IS_VALUE:
            break;
        case GV_IS_PROPERTY_NAME:
            gpr_compile_prn_pr_head(OUT, gv->prn_understood);
            break;
    }
    if (gv->gv_is == GV_IS_OBJECT) gv_compile_parse_name_lines(OUT, gv);
    else gv_compile_lines(OUT, gv);
    switch(gv->gv_is) {
        case GV_IS_COMMAND:
```

```
            WRITE(";\n");
            break;
        case GV_IS_TOKEN:
            gpr_compile_gpr_tail(OUT);
            break;
        case GV_IS_CONSULT:
            gpr_compile_consult_tail(OUT);
            break;
        case GV_IS_OBJECT:
            gpr_compile_parse_name_tail(OUT);
            WRITE(";\n");
            break;
        case GV_IS_VALUE:
            break;
        case GV_IS_PROPERTY_NAME:
            gpr_compile_prn_pr_tail(OUT, gv->prn_understood);
            break;
    }
}
```

The function gv_compile is called from 13/gprv.

§**24.** The special thing about `GV_IS_OBJECT` grammars is that each is attached to a world object WO, and when we compile them we recurse up the kind hierarchy: thus if the red ball is of kind ball which is of kind thing, then the `parse_name` for the red ball consists of grammar lines specified for the red ball, then those specified for all balls, and lastly those specified for all things. (This mimics I6 class-to-instance inheritance.)

```
void gv_compile_parse_name_lines(OUTPUT_STREAM, grammar_verb *gv) {
    world_object *wo2 = gv->wo_understood;
    if (wo2->understand_as_this_object != gv)
        internal_error("link between WO and GV broken");
    LOGIF(GRAMMAR, "Parse_name content for $O:\n", wo2);
    gv_compile_lines(OUT, wo2->understand_as_this_object);
    wo2 = wo2->kind;
    while ((wo2) && (wo2 != kind_kind)) {
        if (wo2->understand_as_this_object) {
            LOGIF(GRAMMAR, "And parse_name content inherited from $O:\n", wo2);
            gv_compile_lines(OUT, wo2->understand_as_this_object);
        }
        wo2 = wo2->kind;
    }
}
```

§**25.** All other grammars are compiled just as they are:

```
void gv_compile_lines(OUTPUT_STREAM, grammar_verb *gv) {
    gl_list_assert_ownership(gv->first_line, gv);                    Mark for later indexing
    sort_grammar_verb(gv);                                  Phase III for the GLs in the GV happens here
    gl_sorted_line_list_compile(OUT, gv->sorted_first_line,
        gv->gv_is, gv, gv_is_genuinely_verbal(gv));                  And Phase IV here
}
```

§**26.** All of that was really Phase IV work (compiling), but a very little Phase III business also happens at this top level. Note that some grammars are compiled more than once (if a red ball and a blue ball are both of kind ball, then compiling grammars for them will also involve compiling grammars for the ball in each case: see above), so the following routine may well be called more than once for the same GV. We only want to sort once, though, so:

```
void sort_grammar_verb(grammar_verb *gv) {
    if (gv->sorted_first_line == NULL)
        gv->sorted_first_line = gl_list_sort(gv->first_line);
}
```

Grammar Lines 13/gl

Purpose

A grammar line is a list of tokens to specify a textual pattern. For example, the NI source for a grammar line might be `"take [something] out"`, which is a sequence of three tokens.

Template interpreter commands

```
4   {-routine:MistakeActionSub}
```

Definitions

¶1. A grammar line is in turn a sequence of tokens. If it matches, it will result in 0, 1 or 2 parameters, though only if the grammar verb owning the line is a genuine `GV_IS_COMMAND` command grammar will the case of 2 parameters be possible. (This is for text matching, say, "put X in Y": the objects X and Y are two parameters resulting.) And in that case (alone), there will also be a `resulting_action`.

A small amount of disjunction is allowed in a grammar line: for instance, "look in/inside/into [something]" consists of five tokens, but only three *lexemes*, basic units to be matched. (The first is "look", the second is "one out of in, inside or into", and the third is an object in scope.) In the following structure we cache the lexeme count since it is fiddly to calculate, and useful when sorting grammar lines into applicability order.

The individual tokens are stored simply as parse tree nodes of type `TOKEN_NT`, and are the children of the node `gl->tokens`, which is why (for now, anyway) there is no grammar token structure.

```
define UNCALCULATED_BONUS -1000000

typedef struct grammar_line {
    struct grammar_line *next_line;                    linked list in creation order
    struct grammar_line *sorted_next_line;             and in applicability order
    struct parse_node *where_grammar_specified;        where found in source
    int original_text;                                 the word number of the double-quoted grammar text...
    struct parse_node *tokens;                         ...which is parsed into this list of tokens
    int lexeme_count;                                  number of lexemes, or -1 if not yet counted
    int understand_when_w1, understand_when_w2;        only when this condition holds
    int pluralised;                                    GV_IS_OBJECT: refers in the plural
    struct action_name *resulting_action;              GV_IS_COMMAND: the action
    int reversed;                                      GV_IS_COMMAND: the two arguments are in reverse order
    int mistaken;                                      GV_IS_COMMAND: is this understood as a mistake?
    int mistake_response_wn;                           if so, reply with the text at this word number
    struct grammar_type gl_type;
    int suppress_compilation;                          has been compiled in a single I6 grammar token already?
    struct grammar_line *next_with_action;             used when indexing actions
    struct grammar_verb *belongs_to_gv;                similarly, used only in indexing
    int general_sort_bonus;                            temporary values used in grammar line sorting
    int understanding_sort_bonus;
    MEMORY_MANAGEMENT
} grammar_line;
```

The structure grammar_line is private to this section.

```
grammar_line *gl_new(int wn, action_name *ac,
    parse_node *token_list, int reversed, int pluralised) {
    grammar_line *gl;
    gl = CREATE(grammar_line);
    gl->original_text = wn;
    gl->resulting_action = ac;
    gl->belongs_to_gv = NULL;
    if (ac != NULL) act_add_gl(ac, gl);
    gl->mistaken = FALSE;
    gl->mistake_response_wn = -1;
    gl->next_with_action = NULL;
    gl->next_line = NULL;
    gl->tokens = token_list;
    gl->where_grammar_specified = current_sentence;
    gl->gl_type = gty_new(TRUE);
    gl->lexeme_count = -1;                                    no count made as yet
    gl->reversed = reversed;
    gl->pluralised = pluralised;
    gl->understand_when_w1 = -1;
    gl->understand_when_w2 = -1;
    gl->suppress_compilation = FALSE;
    gl->general_sort_bonus = UNCALCULATED_BONUS;
    gl->understanding_sort_bonus = UNCALCULATED_BONUS;
    return gl;
}
void log_grammar_line(grammar_line *gl) {
    LOG("<GL%d:$W>", gl->allocation_id,
        gl->tokens->word_ref1, gl->tokens->word_ref2);
}
void gl_set_single_type(grammar_line *gl, specification *gl_value) {
    gty_set_single_type(&(gl->gl_type), gl_value);
}
```

The function gl_new is called from 13/tfg.

The function log_grammar_line is called from 2/dl.

The function gl_set_single_type is called from 13/tfg.

§1. **GL lists.** Grammar lines are themselves generally stored in linked lists (belonging, for instance, to a GV). Here we add a GL to the back of a list.

```
int gl_list_length(grammar_line *list_head) {
    int c = 0;
    grammar_line *posn;
    for (posn = list_head; posn; posn = posn->next_line) c++;
    return c;
}
grammar_line *gl_list_add(grammar_line *list_head, grammar_line *new_gl) {
    new_gl->next_line = NULL;
    if (list_head == NULL) list_head = new_gl;
    else {
```

```
        grammar_line *posn = list_head;
        while (posn->next_line) posn = posn->next_line;
        posn->next_line = new_gl;
    }
    return list_head;
}
int gl_line_list_is_uncensored(grammar_line *list_head) {
    grammar_line *gl;
    for (gl = list_head; gl; gl = gl->next_line) {
        action_name *an = gl->resulting_action;
        if ((an) && (act_is_censored(an) == FALSE)) return TRUE;
    }
    return FALSE;
}
```

The function gl_list_length is called from 13/gv.
The function gl_list_add is called from 13/gv.
The function gl_line_list_is_uncensored is called from 13/gv.

§**2. Two special forms of grammar lines.** GLs can have either or both of two orthogonal special forms: they can be mistaken or conditional. (Mistakes only occur in command grammars, but conditional GLs can occur in any grammar.) GLs of this kind need special support, in that I6 general parsing routines need to be compiled for them to use as tokens: here's where that support is provided. The following step needs to take place before the command grammar (I6 `Verb` directives, etc.) is compiled because of I6's requirement that all GPRs be defined as routines prior to the `Verb` directive using them.

```
void gl_line_list_compile_condition_tokens(OUTPUT_STREAM, grammar_line *list_head) {
    grammar_line *gl;
    for (gl = list_head; gl; gl = gl->next_line) {
        gl_compile_condition_token_as_needed(OUT, gl);
        gl_compile_mistake_token_as_needed(OUT, gl);
    }
}
```

The function gl_line_list_compile_condition_tokens is called from 13/gv.

§**3. Conditional lines.** Some grammar lines take effect only when some circumstance holds: any I7 condition is valid to specify this, with the notation "Understand ... as ... when ...". Such GLs have an "understand when" set, as follows. They compile preceded by a match-no-text token which matches correctly if the condition holds and incorrectly if it fails. For instance, for a command grammar, we might have:

```
* Cond_Token_26 'draw' noun -> Draw

void gl_set_understand_when(grammar_line *gl, int w1, int w2) {
    gl->understand_when_w1 = w1;
    gl->understand_when_w2 = w2;
}
void gl_compile_condition_token_as_needed(OUTPUT_STREAM, grammar_line *gl) {
    if (gl->understand_when_w1 >= 0) {
        ph_stack_frame *phsf;
        phsf = phsf_create_nonphrase_stack_frame();
        OUT = begin_compiling_phrase(OUT);
        begin_code_blocks();
```

```
        specification *spec
            = parse_expression(gl->understand_when_w1, gl->understand_when_w2, CONDITION_EXPCON);
        if (validate_when(spec) == FALSE) {
            LOG("Offending SP of condition: ");
            LOG("Error at: $X", spec);

                gl->allocation_id, current_label);
    }
}
```

The function gl_set_understand_when is called from 13/tfg.

§4. **Mistakes.** These are grammar lines used in command GVs for commands which are accepted but only in order to print nicely worded rejections. A number of schemes were tried for this, for instance producing parser errors and setting `pe` to some high value, but the method now used is for a mistaken line to produce a successful parse at the I6 level, resulting in the (I6 only) action `##MistakeAction`. The tricky part is to send information to the I6 action routine `MistakeActionSub` indicating what the mistake was, exactly: we do this by including, in the I6 grammar, a token which matches empty text and returns a "preposition", so that it has no direct result, but which also sets a special global variable as a side-effect. Thus a mistaken line "act [thing]" comes out as something like:

```
* Mistake_Token_12 'act' noun -> MistakeAction
```

Since the I6 parser accepts the first command which matches, and since none of this can be recursive, the value of this variable at the end of I6 parsing is guaranteed to be the one set during the line causing the mistake.

```
void gl_set_mistake(grammar_line *gl, int wn) {
    gl->mistaken = TRUE;
    gl->mistake_response_wn = wn;
```

```
}
void gl_compile_mistake_token_as_needed(OUTPUT_STREAM, grammar_line *gl) {
    if (gl->mistaken) {
        WRITE("[ Mistake_Token_%d;\n", gl->allocation_id); INDENT;
        WRITE("if (actor ~= player) return GPR_FAIL;\n");
        WRITE("understand_as_mistake_number = %d;\n", 100 + gl->allocation_id);
        WRITE("return GPR_PREPOSITION;\n");
        OUTDENT; WRITE("];\n");
    }
}
void gl_compile_extra_token_for_mistake(OUTPUT_STREAM, grammar_line *gl,
    int gv_is, int current_label) {
    if (gl->mistaken) {
        if (gv_is == GV_IS_COMMAND)
            WRITE("Mistake_Token_%d ", gl->allocation_id);
        else
            internal_error("GLs may only be mistaken in command grammar");
    }
}
int gl_compile_result_of_mistake(OUTPUT_STREAM, grammar_line *gl) {
    if (gl->mistaken) { WRITE(" -> MistakeAction\n"); return TRUE; }
    return FALSE;
}
void compile_MistakeActionSub_routine(OUTPUT_STREAM) {
    WRITE("[ MistakeActionSub;\n"); INDENT;
    WRITE("switch(understand_as_mistake_number) {\n"); INDENT;
    grammar_line *gl;

        if (gl->mistaken) {
            if (gl->mistake_response_wn >= 0) {
                specification *spec;
                current_sentence = gl->where_grammar_specified;
                spec = parse_expression(
                    gl->mistake_response_wn, gl->mistake_response_wn,
                    VALUE_EXPCON);
                WRITE("%d: ParserError(", 100+gl->allocation_id);
                spec_compile(OUT, spec);
                WRITE(");\n");
            }
        }
    WRITE("default: \"I didn't understand that sentence.\";\n");
    OUTDENT; WRITE("}\n");
    WRITE("say__p = 1;\n");
    OUTDENT; WRITE("];\n");
}
```

The function gl_set_mistake is called from 13/tfg.

The function compile_MistakeActionSub_routine is invoked by a command in a `.i6t` template file.

§**5. Single word optimisation.** The grammars used to parse names of objects are normally compiled into `parse_name` routines. But the I6 parser also uses the `name` property, and it is advantageous to squeeze as much as possible into `name` and as little as possible into `parse_name`. The only possible candidates are grammar lines consisting of single unconditional words, as detected by the following routine:

```
int gl_contains_single_unconditional_word(grammar_line *gl) {
    parse_node *pn = gl->tokens->down;
    if ((pn)
        && (pn->next == NULL)
        && (pn_int_annotation(pn, slash_class_ANNOT) == 0)
        && (pn_int_annotation(pn, grammar_token_literal_ANNOT))
        && (gl->pluralised == FALSE)
        && (gl->understand_when_w1 < 0))
        return pn->word_ref1;
    return -1;
}
```

§**6.** This routine looks through a GL list and marks to suppress all those GLs consisting only of single unconditional words, which means they will not be compiled into a `parse_name` routine (or anywhere else). If the `of` file handle is set, then the words in question are printed as I6-style dictionary words to it. In practice, this is done when compiling the `name` property, so that a single scan achieves both the transfer into `name` and the exclusion from `parse_name` of affected GLs.

```
grammar_line *gl_list_take_out_one_word_grammar(OUTPUT_STREAM,
    grammar_line *list_head) {
    grammar_line *gl, *glp;
    for (gl = list_head, glp = NULL; gl; gl = gl->next_line) {
        int wn = gl_contains_single_unconditional_word(gl);
        if (wn >= 0) {
            if (OUT) {
                isn_compile_dictionary_word(OUT, lw_array[wn].lw_text, FALSE);
                WRITE(" ");
            }
            gl->suppress_compilation = TRUE;
        } else glp = gl;
    }
    return list_head;
}
```

The function gl_list_take_out_one_word_grammar is called from 13/gv.

§**7. Phase I: Slash Grammar.** Slashing is an activity carried out on a per-grammar-line basis, so to slash a list of GLs we simply slash each GL in turn.

```
void gl_line_list_slash(grammar_line *gl_head) {
    grammar_line *gl;
    for (gl = gl_head; gl; gl = gl->next_line) {
        slash_grammar_line(gl);
    }
}
```

The function gl_line_list_slash is called from 13/gv.

§**8.** Now the actual slashing process, which does not descend to tokens. We remove any slashes, and fill in positive numbers in the `qualifier` field corresponding to non-singleton equivalence classes. Thus "take up/in all washing/laundry/linen" begins as 10 tokens, three of them forward slashes, and ends as 7 tokens, with `qualifier` values 0, 1, 1, 0, 2, 2, 2, for four equivalence classes in turn. Each equivalence class is one lexical unit, or "lexeme", so the lexeme count is then 4.

```
void slash_grammar_line(grammar_line *gl) {
    parse_node *pn;
    int alternatives_group = 0;
    current_sentence = gl->where_grammar_specified;                    to report problems
    if (gl->tokens == NULL)
        internal_error("Null tokens on grammar");
    LOGIF(GRAMMAR_CONSTRUCTION, "Preparing grammar line:\n$T", gl->tokens);
    for (pn = gl->tokens->down; pn; pn = pn->next)
        pn_annotate_int(pn, slash_class_ANNOT, 0);
    for (pn = gl->tokens->down; pn; pn = pn->next) {
        if ((pn->next != NULL) && [[pn->next == FORWARDSLASH]]) {          slash follows:
            if (pn_int_annotation(pn, slash_class_ANNOT) == 0)
                alternatives_group++;                                  start new equiv class
            pn_annotate_int(pn, slash_class_ANNOT,
                alternatives_group);                                make two sides of slash equiv
            if (pn->next->next)
                pn_annotate_int(pn->next->next, slash_class_ANNOT, alternatives_group);
            pn->next = pn->next->next;                          excise the slash from the token list
        }
    }
    LOGIF(GRAMMAR_CONSTRUCTION, "Regrouped as:\n$T", gl->tokens);
    for (pn = gl->tokens->down; pn; pn = pn->next)
        if ((pn_int_annotation(pn, slash_class_ANNOT) > 0) &&
            (pn_int_annotation(pn, grammar_token_literal_ANNOT) == FALSE)) {
            sentence_problem(_P_(C13OverAmbitiousSlash),
                "the slash '/' can only be used between single literal words",
                "so 'underneath/under/beneath' is allowed but "
                "'beneath/[florid ways to say under]/under' isn't.");
            break;
        }
    gl->lexeme_count = 0;
```

```
    for (pn = gl->tokens->down; pn; pn = pn->next) {
        int i = pn_int_annotation(pn, slash_class_ANNOT);
        if (i > 0)
            while ((pn->next) && (pn_int_annotation(pn->next, slash_class_ANNOT) == i))
                pn = pn->next;
        gl->lexeme_count++;
    }
    LOGIF(GRAMMAR_CONSTRUCTION, "Slashed as:\n$T", gl->tokens);
}
```

§**9. Phase II: Determining Grammar.** Here there is substantial work to do both at the line list level and on individual lines, and the latter does recurse down to token level too.

The following routine calculates the type of the GL list as the union of the types of the GLs within it, where union means the narrowest type such that every GL in the list casts to it. We return null if there are no GLs in the list, or if the GLs all return null types, or if an error occurs. (Note that actions in command verb grammars are counted as null for this purpose, since a grammar used for parsing the player's commands is not also used to determine a value.)

```
specification *gl_line_list_determine(grammar_line *list_head,
    int depth, int gv_is, grammar_verb *gv, int genuinely_verbal) {
    grammar_line *gl;
    int first_flag = TRUE;
    specification *spec_union = NULL;
    LOGIF(GRAMMAR_CONSTRUCTION, "Determining GL list for $G\n", gv);
    for (gl = list_head; gl; gl = gl->next_line) {
        specification *spec_of_line =
            gl_determine(gl, depth, gv_is, gv, genuinely_verbal);
        if (first_flag) {                              initially no expectations: spec_union is meaningless
            spec_union = spec_of_line;                                          so we set it to the first result
            first_flag = FALSE;
            continue;
        }
        if ((spec_union == NULL) && (spec_of_line == NULL))
            continue;                                  we expected to find no result, and did: so no problem
        if ((spec_union) && (spec_of_line)) {
            if (can_we_match_value_descriptions(spec_union, spec_of_line) == ALWAYS_MATCH) {
                spec_union = spec_of_line;                          here spec_of_line was a wider type
                continue;
            }
            if (can_we_match_value_descriptions(spec_of_line, spec_union) == ALWAYS_MATCH) {
                continue;                                       here spec_union was already wide enough
            }
        }
        current_sentence = gl->where_grammar_specified;
        sentence_problem(_P_(C13MixedOutcome),
            "grammar tokens must have the same outcome whatever the way they are "
            "reached",
            "so writing a line like 'Understand \"within\" or \"next to "
            "[something]\" as \"[my token]\" must be wrong: one way it produces "
            "a thing, the other way it doesn't.");
        spec_union = NULL;
        break;                                 to prevent the problem being repeated for the same grammar
    }
    LOGIF(GRAMMAR_CONSTRUCTION, "Union: $S\n");
    return spec_union;
}
```

The function gl_line_list_determine is called from 13/gv.

§**10.** There are three tasks here: to determine the type of the GL, to issue a problem if this type is impossibly large, and to calculate two numerical quantities used in sorting GLs: the "general sorting bonus" and the "understanding sorting bonus" (see below).

```
specification *gl_determine(grammar_line *gl, int depth,
    int gv_is, grammar_verb *gv, int genuinely_verbal) {
    specification *spec = NULL;
    parse_node *pn, *pn2;
    int nulls_count, i, nrv, line_length;
    current_sentence = gl->where_grammar_specified;

    gl->understanding_sort_bonus = 0;
    gl->general_sort_bonus = 0;

    nulls_count = 0;                                        number of tokens with null results

    pn = gl->tokens->down;                                  start from first token
    if ((genuinely_verbal) && (pn)) pn = pn->next;          unless it's a command verb

    for (pn2=pn, line_length=0; pn2; pn2 = pn2->next) line_length++;

    for (i=0; pn; pn = pn->next, i++) {
        if (pn_get_node_type(pn) != TOKEN_NT)
            internal_error("Bogus node types on grammar");

        spec = gtok_determine(pn, depth);
        LOGIF(GRAMMAR_CONSTRUCTION, "Result of token <$W> is $S\n",
            pn->word_ref1, pn->word_ref2, spec);

        if (spec) {
            if ((spec_is_generic_CONSTANT(spec)) &&
                (is_kova(spec_get_kind_of_value(spec), UNDERSTANDING_TY))) {        "[text]" token
                int usb_contribution = i - 100;
                if (usb_contribution >= 0) usb_contribution = -1;
                usb_contribution = 100*usb_contribution + (line_length-1-i);
                gl->understanding_sort_bonus += usb_contribution;                   reduces!
            }
            gl->general_sort_bonus +=
                gty_add_type(&(gl->gl_type), spec, gtok_is_multiple(pn));
        } else nulls_count++;
    }

    nrv = gty_get_no_resulting_values(&(gl->gl_type));
    if (nrv == 0) gl->general_sort_bonus = 100*nulls_count;
    if (gv_is == GV_IS_COMMAND) spec = NULL;
    else {
        if (nrv < 2) spec = gty_get_single_type(&(gl->gl_type));
        else sentence_problem(_P_(C13TwoValuedToken),
            "there can be at most one varying part in the definition of a "
            "named token",
            "so 'Understand \"button [a number]\" as \"[button indication]\"' "
            "is allowed but 'Understand \"button [a number] on [something]\" "
            "as \"[button indication]\"' is not.");
    }

    LOGIF(GRAMMAR_CONSTRUCTION,
        "Determined $g: lexeme count %d, sorting bonus %d, arguments %d, "
        "fixed initials %d, type $S\n",
        gl, gl->lexeme_count, gl->general_sort_bonus, nrv,
        gl->understanding_sort_bonus, spec);
```

```
    return spec;
}
```

§**11. Phase III: Sort Grammar.** Insertion sort is used to take the linked list of GLs and construct a separate, sorted version. This is not the controversial part.

```
grammar_line *gl_list_sort(grammar_line *list_head) {
    grammar_line *gl, *gl2, *gl3, *sorted_head;
    if (list_head == NULL) return NULL;
    sorted_head = list_head;
    list_head->sorted_next_line = NULL;
    gl = list_head;
    while (gl->next_line) {
        gl = gl->next_line;
        gl2 = sorted_head;
        if (grammar_line_must_precede(gl, gl2)) {
            sorted_head = gl;
            gl->sorted_next_line = gl2;
            continue;
        }
        while (gl2) {
            gl3 = gl2;
            gl2 = gl2->sorted_next_line;
            if (gl2 == NULL) {
                gl3->sorted_next_line = gl;
                break;
            }
            if (grammar_line_must_precede(gl, gl2)) {
                gl3->sorted_next_line = gl;
                gl->sorted_next_line = gl2;
                break;
            }
        }
    }
    return sorted_head;
}
```

The function gl_list_sort is called from 13/gv.

§**12.** This is the controversial part: the routine which decides whether one GL takes precedence (i.e., is parsed earlier than and thus in preference to) another GL. This algorithm has been hacked many times to try to reach a position which pleases all designers: something of a lost cause. The basic motivation is that we need to sort because the various parsers of I7 grammar (`parse_name` routines, general parsing routines, the I6 command parser itself) all work by returning the first match achieved. This means that if grammar line L2 matches a superset of the texts which grammar line L1 matches, then L1 should be tried first: trying them in the order L2, L1 would mean that L1 could never be matched, which is surely contrary to the designer's intention. (Compare the rule-sorting algorithm, which has similar motivation but is entirely distinct, though both use the same primitive methods for comparing types of single values, i.e., at stages 5b1 and 5c1 below.)

Recall that each GL has a numerical USB (understanding sort bonus) and GSB (general sort bonus). The following rules are applied in sequence:

(1) Higher USBs beat lower USBs.

(2a) For sorting GLs in player-command grammar, shorter lines beat longer lines, where length is calculated as the lexeme count.

(2b) For sorting all other GLs, longer lines beat shorter lines.

(3) Mistaken commands beat unmistaken commands.

(4) Higher GSBs beat lower GSBs.

(5a) Fewer resulting values beat more resulting values.

(5b1) A narrower first result type beats a wider first result type, if there is a first result.

(5b2) A multiples-disallowed first result type beats a multiples-allowed first result type, if there is a first result.

(5c1) A narrower second result type beats a wider second result type, if there is a second result.

(5c2) A multiples-disallowed second result type beats a multiples-allowed second result type, if there is a second result.

(6) Conditional lines (with a "when" proviso, that is) beat unconditional lines.

(7) The grammar line defined earlier beats the one defined later.

Rule 1 is intended to resolve awkward ambiguities involved with command grammar which includes "[text]" tokens. Each such token subtracts 10000 from the USB of a line but adds back 100 times the token position (which is at least 0 and which we can safely suppose is less than 99: we truncate just in case so that every `"[text]"` certainly makes a negative contribution of at least −100) and then subtracts off the number of tokens left on the line.

Because a high USB gets priority, and "[text]" tokens make a negative contribution, the effect is to relegate lines containing "[text]" tokens to the bottom of the list – which is good because "[text]" voraciously eats up words, matching more or less anything, so that any remotely specific case ought to be tried first. The effect of the curious addition back in of the token position is that later-placed "[text]" tokens are tried before earlier-placed ones. Thus `"read chapter [text]"` has a USB of −98, and takes precedence over `"read [text]"` with a USB of −99, but both are beaten by just `"read [something]"` with a USB of 0. The effect of the subtraction back of the number of tokens remaining is to ensure that `"read [token] backwards"` takes priority over `"read [token]"`.

The voracity of `"[text]"`, and its tendency to block out all other possibilities unless restrained, has to be addressed by this lexically based numerical calculation because it works in a lexical sort of way: playing with the types system to prefer `DESCRIPTION/UNDERSTANDING` over, say, `VALUE/OBJECT` would not be sufficient.

The most surprising point here is the asymmetry in rule 2, which basically says that when parsing commands typed at the keyboard, shorter beats longer, whereas in all other settings longer beats shorter. This arises because the I6 parser, at run time, traditionally works that way: I6 command grammars are normally stored with short forms first and long forms afterward. The I6 parser can afford to do this because it is matching text of known length: if parsing TAKE FROG FROM AQUARIUM, it will try TAKE FROG first but is able to reject this as not matching the whole text. In other parsing settings, we are trying to make a maximum-length match against a potentially infinite stream of words, and it is therefore important to try to match WATERY CASCADE EFFECT before WATERY CASCADE when looking at text like WATERY CASCADE EFFECT IMPRESSES PEOPLE, given that the simplistic parsers we compile generally return the first match found.

Rule 3, that mistakes beat non-mistakes, was in fact rule 1 during 2006: it seemed logical that since mistakes were exceptional cases, they would be better checked earlier before moving on to general cases. However, an example provided by Eric Eve showed that although this was logically correct, the I6 parser would try to auto-complete lengthy mistakes and thus fail to check subsequent commands. For this reason, `"look behind [something]"` as a mistake needs to be checked after `"look"`, or else the I6 parser will respond to the command LOOK by replying "What do you want to look behind?" – and then saying that you are mistaken.

Rule 4 is intended as a lexeme-based tiebreaker. We only get here if there are the same number of lexemes in the two GLs being compared. Each is given a GSB score as follows: a literal lexeme, which produces no result, such as `"draw"` or `"in/inside/within"`, scores 100; all other lexemes score as follows:

– `"[things inside]"` scores a GSB of 10 as the first parameter, 1 as the second;

– `"[things preferably held]"` similarly scores a GSB of 20 or 2;

– `"[other things]"` similarly scores a GSB of 20 or 2;

– `"[something preferably held]"` similarly scores a GSB of 30 or 3;

– any token giving a logical description of some class of objects, such as `"[open container]"`, similarly scores a GSB of 50 or 5;

– and any remaining token (for instance, one matching a number or some other kind of value) scores a GSB of 0.

Literals score highly because they are structural, and differentiate cases: under the superset rule, `"look up [thing]"` must be parsed before `"look [direction] [thing]"`, and it is only the number of literals which differentiates these cases. If two lines have an equal number of literals, we now look at the first resultant lexeme. Here we find that a lexeme which specifies an object (with a GSB of at least 10/1) beats a lexeme which only specifies a value. Thus the same text will be parsed against objects in preference to values, which is sensible since there are generally few objects available to the player and they are generally likely to be the things being referred to. Among possible object descriptions, the very general catch-all special cases above are given lower GSB scores than more specific ones, to enable the more specific cases to go first.

Rule 5a is unlikely to have much effect: it is likely to be rare for GL lists to contain GLs mixing different numbers of results. But Rule 5b1 is very significant: it causes `"draw [animal]"` to have precedence over `"draw [thing]"`, for instance. Rule 5b2 ensures that `"draw [thing]"` takes precedence over `"draw [things]"`, which may be useful to handle multiple and single objects differently.

The motivation for rule 6 is similar to the case of "when" clauses for rules in rulebooks: it ensures that a match of `"draw [thing]"` when some condition holds beats a match of `"draw [thing]"` at any time, and this is necessary under the strict superset principle.

To get to rule 7 looks difficult, given the number of things about the grammar lines which must match up – same USB, GSB, number of lexemes, number of resulting types, equivalent resulting types, same conditional status – but in fact it isn't all that uncommon. Equivalent pairs produced by the Standard Rules include:

`"get off [something]"` and `"get in/into/on/onto [something]"`

`"turn on [something]"` and `"turn [something] on"`

Only the second of these pairs leads to ambiguity, and even then only if an object has a name like ON VISION ON – perhaps a book about the antique BBC children's television programme *Vision On* – so that the command TURN ON VISION ON would match both of the alternative GLs.

    return FALSE;
}
```

§13. Phase IV: Compile Grammar. At this level we compile the list of GLs in sorted order: this is what the sorting was all for. In certain cases, we skip any GLs marked as "one word": these are cases arising from, e.g., "Understand "frog" as the toad.", where we noticed that the GL was a single word and included it in the `name` property instead. This is faster and more flexible, besides writing tidier code.

The need for this is not immediately obvious. After all, shouldn't we have simply deleted the GL in the first place, rather than leaving it in but marking it? The answer is no, because of the way inheritance works: values of the `name` property accumulate from class to instance in I6, since `name` is additive, but grammar doesn't.

```
void gl_sorted_line_list_compile(OUTPUT_STREAM, grammar_line *list_head,
    int gv_is, grammar_verb *gv, int genuinely_verbal) {
    grammar_line *gl;
    INDENT;
    for (gl = list_head; gl; gl = gl->sorted_next_line)
        if (gl->suppress_compilation == FALSE)
            compile_grammar_line(OUT, gl, gv_is, gv, genuinely_verbal);
    OUTDENT;
}
```

The function gl_sorted_line_list_compile is called from 13/gv.

§14. The following apparently global variables are used to provide a persistent state for the routine below, but are not accessed elsewhere. The label counter is reset at the start of each GV's compilation, though this is a purely cosmetic effect.

```
int current_grammar_block = 0;
int current_label = 1;
void gl_reset_labels(void) {
    current_label = 1;
}
```

The function gl_reset_labels is called from 13/gv.

§15. As fancy as the following routine may look, it contains very little. What complexity there is comes from the fact that command GVs are compiled very differently to all others (most grammars are compiled in "code mode", generating procedural I6 statements, but command GVs are compiled to lines in `Verb` directives) and that GLs resulting in actions (i.e., GLs in command GVs) have not yet been type-checked, whereas all others have.

```
void compile_grammar_line(OUTPUT_STREAM, grammar_line *gl, int gv_is, grammar_verb *gv,
    int genuinely_verbal) {
    parse_node *pn;

    }
    current_label++;
    return;
}
```

§16. Indexing by grammar. This is the more obvious form of indexing: we show the grammar lines which make up an individual GL. (For instance, this is used in the Actions index to show the grammar for an individual command word, by calling the routine below for that command word's GV.) Such an index list is done in sorted order, so that the order of appearance in the index corresponds to the order of parsing – this is what the reader of the index is interested in.

```
void gl_sorted_list_index_normal(grammar_line *list_head, char *headword) {
    grammar_line *gl;
    for (gl = list_head; gl; gl = gl->sorted_next_line)
        gl_index_normal(gl, headword);
}
void gl_index_normal(grammar_line *gl, char *headword) {
    action_name *an = gl->resulting_action;
    if ((an == NULL) || (act_is_censored(an))) return;
    index_anchor(headword);
    if (act_is_out_of_world(an))
        INDEX("<font color=\"#800000\">");
    INDEX("&quot;");
    index_verb_definition(lw_array[gl->original_text].lw_text, headword);
    INDEX("&quot;");
    index_link(lw_array[gl->original_text].lw_source);
    INDEX(" - <i>");
    print_raw_text_to_file(an->word_ref1, an->word_ref2, ifl);
    index_below_link(an_get_I6_representation(an));
    index_detail_link("A", an->allocation_id, TRUE);
    if (gl->reversed) INDEX(" (reversed)");
    INDEX("</i>");
    if (act_is_out_of_world(an))
        INDEX("</font>");
    INDEX("<br>");
}
```

The function gl_sorted_list_index_normal is called from 13/gv.

§17. Indexing by action. Grammar lines are typically indexed twice: the other time is when all grammar lines belonging to a given action are tabulated. Special linked lists are kept for this purpose, and this is where we unravel them and print to the index. The question of sorted vs unsorted is meaningless here, since the GLs appearing in such a list will typically belong to several different GVs. (As it happens, they appear in order of creation, i.e., in source text order.)

Tiresomely, all of this means that we need to store "uphill" pointers in GLs: back up to the GVs that own them. The following routine does this for a whole list of GLs:

```
void gl_list_assert_ownership(grammar_line *list_head, grammar_verb *gv) {
    grammar_line *gl;
    for (gl = list_head; gl; gl = gl->next_line)
        gl->belongs_to_gv = gv;
}
```

The function gl_list_assert_ownership is called from 13/gv.

§**18.** And this routine accumulates the per-action lists of GLs:

```
void gl_list_with_action_add(grammar_line *list_head, grammar_line *gl) {
    if (list_head == NULL) internal_error("tried to add to null action list");
    while (list_head->next_with_action)
        list_head = list_head->next_with_action;
    list_head->next_with_action = gl;
}
```

The function gl_list_with_action_add is called from 11/act.

§**19.** Finally, here we index an action list of GLs, each getting a line in the HTML index.

```
int gl_index_list_with_action(grammar_line *gl) {
    int said_something = FALSE;
    while (gl != NULL) {
        if (gl->belongs_to_gv) {
            int vwn = gv_get_verb_wn(gl->belongs_to_gv);
            if (vwn != -1) {
                open_html_paragraph(ifl, 2, "hanging");
                INDEX("&quot;");
                index_verb_definition(lw_array[gl->original_text].lw_text,
                    lw_array[vwn].lw_text);
                INDEX("&quot;");
                index_link(lw_array[gl->original_text].lw_source);
                if (gl->reversed) INDEX(" <i>reversed</i>");
                INDEX("</p>");
                said_something = TRUE;
            }
        }
        gl = gl->next_with_action;
    }
    return said_something;
}
```

The function gl_index_list_with_action is called from 11/act.

Grammar Types 13/gty

Purpose

Some grammar text specifies one or more values, and we need to keep track of their data type(s). Here we manage the data structure doing this.

Definitions

```
typedef struct grammar_type {
    int no_resulting_values;                    number of resulting values: 0, 1 or 2; or -1
    struct specification *first_type;                                  and their types
    struct specification *second_type;
    int first_multiplicity;                        lines only: allow a multiple object here?
    int second_multiplicity;                       lines only: allow a multiple object here?
} grammar_type;
```

The structure grammar_type is private to this section.

```
grammar_type gty_new(int supports_return_type) {
    grammar_type gty;
    gty.first_type = NULL;
    gty.second_type = NULL;
    gty.first_multiplicity = FALSE;
    gty.second_multiplicity = FALSE;
    if (supports_return_type)
        gty.no_resulting_values = 0;
    else
        gty.no_resulting_values = -1;
    return gty;
}
```

The function gty_new is called from 13/gv and 13/gl.

§**1.** The multiplication by 10 here is explained in the discussion of GSB tallying during GL sorting in "Grammar Lines". Do not amend it without changing that discussion.

```
int gty_add_type(grammar_type *gty, specification *spec,
    int multiple_flag) {
    switch((gty->no_resulting_values)++) {
        case 0:
            gty->first_type = spec;
            gty->first_multiplicity = multiple_flag;
            return 10*(spec_get_data(spec, GRAMMAR_TOKEN_SCORE_SPDATA));
        case 1:
            gty->second_type = spec;
            gty->second_multiplicity = multiple_flag;
            return spec_get_data(spec, GRAMMAR_TOKEN_SCORE_SPDATA);
        case 2:
            sentence_problem(_P_(C13ThreeValuedLine),
                "there can be at most two varying parts to a line of grammar",
                "so 'put [something] in [a container]' is allowed but 'put "
                "[something] in [something] beside [a door]' is not.");
```

```
    }
    return 0;
}

§**2.** The behaviour of this sorting routine is documented in the discussion of GL sorting in "Grammar Lines". Do not amend it without changing that discussion.

```
int gtk_must_precede(grammar_type *gty1, grammar_type *gty2) {
    int cs;
    if ((gty1->no_resulting_values) < (gty2->no_resulting_values)) return TRUE;
    if ((gty1->no_resulting_values) > (gty2->no_resulting_values)) return FALSE;
    if (gty1->no_resulting_values == 0) return NOT_APPLICABLE;
    cs = compare_specificity_of_spec(gty1->first_type, gty2->first_type);
    if (cs == 1) return TRUE;
    if (cs == -1) return FALSE;
    if ((gty1->first_multiplicity) && (gty2->first_multiplicity == FALSE))
        return FALSE;
    if ((gty1->first_multiplicity == FALSE) && (gty2->first_multiplicity))
        return TRUE;
    if (gty1->no_resulting_values == 1) return NOT_APPLICABLE;
    cs = compare_specificity_of_spec(gty1->second_type, gty2->second_type);
    if (cs == 1) return TRUE;
    if (cs == -1) return FALSE;
    if ((gty1->second_multiplicity) && (gty2->second_multiplicity == FALSE))
        return FALSE;
    if ((gty1->second_multiplicity == FALSE) && (gty2->second_multiplicity))
        return TRUE;
    return NOT_APPLICABLE;
}
```

The function gtk_must_precede is called from 13/gl.

Grammar Tokens 13/gtok

Purpose

To handle grammar at the level of individual tokens. I7 grammar tokens correspond in a 1-to-1 way with I6 tokens: here we determine the I7 type a token represents (if any) and compile it to its I6 grammar token equivalent as needed.

13/gtok.§2 Multiple tokens; §3-7 The special tokens; §8 Phase II: Determining Grammar; §9 Phase IV: Compiling Grammar

---

Definitions

¶1. I7 tokens are (at present) stored simply as parse tree nodes of type `TOKEN_NT`, with meaningful information hidden in annotations. At one time I thought this was a simple arrangement, but it now seems obfuscatory, so at some point I plan to create a "grammar token" structure to avoid these arcane annotations of the parse tree.

`grammar_token_nonliteral_ANNOT` is clear for literal words such as `"into"` and set for square-bracketed tokens such as `"[something]"`.

`index` stores the GSB scoring contribution made by the token to the GL sorting algorithm.

The `grammar_token_code_ANNOT` annotation is meaningful only for parse nodes with an evaluation of type `DESCRIPTION`. These are tokens which describe a range of objects. Examples include "[open container]", which compiles to an I6 noun filter, "[any container]", which compiles to an I6 scope filter, or "[things]", one of a small number of special cases compiling to primitive I6 parser tokens. The annotation holds the allocation ID for the noun/scope filter structure built for the occasion in the former cases, and one of the following constants in the latter case. (These must all have negative values in order not to clash with allocation IDs 0, 1, 2, ..., and clearly must all be different, but otherwise the values are not significant and there is no preferred order.)

For tokens with any other evaluation, `general_purpose` is always 0, so that the special values below cannot arise.

define `NOUN_TOKEN_GTC -1` — *I6* `noun`
define `MULTI_TOKEN_GTC -2` — *I6* `multi`
define `MULTIINSIDE_TOKEN_GTC -3` — *I6* `multiinside`
define `MULTIHELD_TOKEN_GTC -4` — *I6* `multiheld`
define `HELD_TOKEN_GTC -5` — *I6* `held`
define `CREATURE_TOKEN_GTC -6` — *I6* `creature`
define `TOPIC_TOKEN_GTC -7` — *I6* `topic`
define `MULTIEXCEPT_TOKEN_GTC -8` — *I6* `multiexcept`

---

§**1.** Tokens are created when text such as "drill [something] with [something]" is parsed, from an Understand sentence or elsewhere. The following routine builds a token list in the parse tree as children of `pn`:

```
void gtok_break_into_tokens(parse_node *pn, int w1, int w2) {
    int i;
    parse_node *newpn;
    if ((i = is_word_intermediate(COMMA_V, w1, w2))>=0) {
        gtok_break_into_tokens(pn, w1, i-1);
        gtok_break_into_tokens(pn, i+1, w2);
        return;
    }
    if (is_kova(is_a_literal(w1, w2), TEXT_TY)) {
```

```
        dequote_word(w1);
        if (*(lw_array[w1].lw_text) == 0) return;
        feed_into_lexer(lw_array[w1].lw_text, FALSE, TRUE);
        w1 = lexer_feed_w1; w2 = lexer_feed_w2;
        for (i=w1; i<=w2; i++) {
            newpn = new_nounphrase_raw(i, i);
            pn_set_node_type(newpn, TOKEN_NT);
            pn_annotate_int(newpn, grammar_token_literal_ANNOT, TRUE);
            graft(newpn, pn);
        }
        return;
    }
    newpn = new_nounphrase_raw(w1, w2);
    pn_set_node_type(newpn, TOKEN_NT);
    pn_annotate_int(newpn, grammar_token_literal_ANNOT, FALSE);
    graft(newpn, pn);
}

int gtok_is_literal(parse_node *pn) {
    return pn_int_annotation(pn, grammar_token_literal_ANNOT);
}
```

The function gtok_break_into_tokens is called from 13/tfg.
The function gtok_is_literal is called from 13/tfg.

§2. Multiple tokens.

A multiple token is one which permits multiple matches in the I6 parser: for instance, permits the use of "all".

```
int gtok_is_multiple(parse_node *pn) {
    switch (pn_int_annotation(pn, grammar_token_code_ANNOT)) {
        case MULTI_TOKEN_GTC:
        case MULTIINSIDE_TOKEN_GTC:
        case MULTIHELD_TOKEN_GTC:
        case MULTIEXCEPT_TOKEN_GTC:
            return TRUE;
    }
    return FALSE;
}
```

The function gtok_is_multiple is called from 13/gl.

§**3. The special tokens.** Do not change any of these GTC numbers without first checking and updating the discussion of GL sorting in Grammar Lines:

```
int gsb_for_special_token(int gtc) {
    switch(gtc) {
        case NOUN_TOKEN_GTC: return 0;
        case MULTI_TOKEN_GTC: return 0;
        case MULTIINSIDE_TOKEN_GTC: return 1;
        case MULTIHELD_TOKEN_GTC: return 2;
        case HELD_TOKEN_GTC: return 3;
        case CREATURE_TOKEN_GTC: return 0;
        case TOPIC_TOKEN_GTC: return -1;
        case MULTIEXCEPT_TOKEN_GTC: return 2;
        default: internal_error("tried to find GSB for invalid GTC");
    }
    return 0;                                                    to prevent a gcc error: never reached
}
```

§**4.** These translate into I6 as follows:

```
char *i6_token_for_special_token(int gtc) {
    switch(gtc) {
        case NOUN_TOKEN_GTC: return "noun";
        case MULTI_TOKEN_GTC: return "multi";
        case MULTIINSIDE_TOKEN_GTC: return "multiinside";
        case MULTIHELD_TOKEN_GTC: return "multiheld";
        case HELD_TOKEN_GTC: return "held";
        case CREATURE_TOKEN_GTC: return "creature";
        case TOPIC_TOKEN_GTC: return "topic";
        case MULTIEXCEPT_TOKEN_GTC: return "multiexcept";
        default: internal_error("tried to find I6 token for invalid GTC");
    }
    return "";                                                   to prevent a gcc error: never reached
}
char *i6_constant_for_special_token(int gtc) {
    switch(gtc) {
        case NOUN_TOKEN_GTC: return "NOUN_TOKEN";
        case MULTI_TOKEN_GTC: return "MULTI_TOKEN";
        case MULTIINSIDE_TOKEN_GTC: return "MULTIINSIDE_TOKEN";
        case MULTIHELD_TOKEN_GTC: return "MULTIHELD_TOKEN";
        case HELD_TOKEN_GTC: return "HELD_TOKEN";
        case CREATURE_TOKEN_GTC: return "CREATURE_TOKEN";
        case TOPIC_TOKEN_GTC: return "TOPIC_TOKEN";
        case MULTIEXCEPT_TOKEN_GTC: return "MULTIEXCEPT_TOKEN";
        default: internal_error("tried to find I6 constant for invalid GTC");
    }
    return "";                                                   to prevent a gcc error: never reached
}
```

§**5.** The special tokens all return a value in I6 which needs a data type to be used in I7: these are defined by the following routine.

```
kind_of_value *data_type_for_special_token(int gtc) {
    if (gtc == TOPIC_TOKEN_GTC) return kova(UNDERSTANDING_TY);
    return kova(OBJECT_TY);
}
```

§**6.** The I7 equivalent names for these special tokens are as follows:

```
int parse_special_token(int w1, int w2) {
    if [[w1, w2 == something]] return NOUN_TOKEN_GTC;
    if [[w1, w2 == anything]] return NOUN_TOKEN_GTC;
    if [[w1, w2 == things]] return MULTI_TOKEN_GTC;
    if [[w1, w2 == things inside]] return MULTIINSIDE_TOKEN_GTC;
    if [[w1, w2 == things preferably held]] return MULTIHELD_TOKEN_GTC;
    if [[w1, w2 == something preferably held]] return HELD_TOKEN_GTC;
    if [[w1, w2 == other things]] return MULTIEXCEPT_TOKEN_GTC;
    if [[w1, w2 == someone]] return CREATURE_TOKEN_GTC;
    if [[w1, w2 == somebody]] return CREATURE_TOKEN_GTC;
    if [[w1, w2 == anybody]] return CREATURE_TOKEN_GTC;
    if [[w1, w2 == anyone]] return CREATURE_TOKEN_GTC;
    if [[w1, w2 == text]] return TOPIC_TOKEN_GTC;
    if [[w1, w2 == something held]] {
        incompatible_change_problem(
            "something held", "something", "something preferably held");
        return HELD_TOKEN_GTC;
    }
    if [[w1, w2 == things held]] {
        incompatible_change_problem(
            "things held", "things", "things preferably held");
        return MULTIHELD_TOKEN_GTC;
    }
    return 0;
}
```

§**7.** Something of an extended mea culpa: but it had the desired effect, in that nobody complained about what might have been a controversial change.

```
void incompatible_change_problem(char *token_tried, char *token_instead,
    char *token_better) {
    quote_source(1, current_sentence);
    quote_text(2, token_tried);
    quote_text(3, token_instead);
    quote_text(4, token_better);
    handmade_problem(_P_(C13ObsoleteHeldTokens));
    issue_problem_segment(
        "In the sentence %1, you used the '[%2]' as a token, which was "
        "allowed in the early Public Beta versions of Inform 7, but became "
        "out of date in August 2006%|. A change was then made so that if an "
        "action needed to apply to something which was carried, this would "
        "now be specified when the action is created - not in the Understand "
        "line for it. For instance, one might say 'Dismantling is an action "
        "which applies to one carried thing', instead of '...which applies "
        "to one thing', and then write grammar such as 'Understand \"dismantle "
        "[something] as dismantling' instead of '...[something held]...'. "
        "So you probably need to change your '[%2]' token to '[%3]', and "
        "change the action's definition (unless it is a built-in action "
        "such as 'dropping'). An alternative, though, for fine-tuning is to "
        "change it to '[%4]', which allows anything to be Understood, but "
        "in cases of ambiguity tends to guess that something held is more "
        "likely to be what the player means than something not held.");
    issue_problem_end();
}
```

§**8. Phase II: Determining Grammar.** Slashing does not recurse down to individual tokens, so the first time we look seriously at tokens is in Phase II.

```
specification *gtok_determine(parse_node *pn, int depth) {
    int w1, w2;
    specification *spec = NULL;
    grammar_verb *gv;
    if (pn_int_annotation(pn, grammar_token_literal_ANNOT)) return NULL;
    [[w1, w2 <-- pn]];
    if ([[w1, w2 == topic]] || [[w1, w2 == a topic]]) {
        quote_source(1, current_sentence);
        quote_words(2, pn->word_ref1, pn->word_ref2);
        handmade_problem(_P_(C13UseTextNotTopic));
        issue_problem_segment(
            "The grammar token '%2' in the sentence %1 would in some "
            "ways be the right logical way to suggest 'any words at "
            "all here', but (partly for historical reasons) Inform in "
            "fact uses the special syntax '[text]' for that.");
        issue_problem_end();
        return NULL;
    }
    if ([[w1, w2 == object]] || [[w1, w2 == an object]]) {
        quote_source(1, current_sentence);
```

```

    }
    return spec;
}
```

The function gtok_determine is called from 13/gl.

§**9. Phase IV: Compiling Grammar.** Tokens play no direct part in Phase III either, having made their contribution earlier by recording their GSB scores instead. So we next see them at compilation time.

In code mode, we compile a test that the token matches, jumping to the failure label if it doesn't, and setting the I6 local variable `rv` to a suitable GPR return value if it does match and produces an outcome. We are allowed to use the I6 local `w` for temporary storage, but nothing else.

```
int ol_loop_counter = 0;
kind_of_value *gtok_compile(OUTPUT_STREAM, parse_node *pn, int code_mode,
    char *failure_label, int consult_mode) {
    int wn = pn->word_ref1;
    specification *spec;
    binary_predicate *bp;
    grammar_verb *gv;
    if (pn_int_annotation(pn, grammar_token_literal_ANNOT)) {
        if (code_mode) {
            WRITE("if (NextWordStopped() ~= ");
            isn_compile_dictionary_word(OUT, lw_array[wn].lw_text, FALSE);
            WRITE(") jump %s;\n", failure_label);
        } else isn_compile_dictionary_word(OUT, lw_array[wn].lw_text, FALSE);
        return NULL;
    }
    bp = pn_get_grammar_token_relation(pn);
    if (bp) {
        WRITE("ArticleDescriptors(); w = wn;\n");
        if (bp == a_contains_b_predicate)
            WRITE("if (self hasnt container) jump %s;\n", failure_label);
        if (bp == a_supports_b_predicate)
            WRITE("if (self hasnt supporter) jump %s;\n", failure_label);
        if ((bp == a_has_b_predicate) || (bp == a_wears_b_predicate) ||
            (bp == a_carries_b_predicate))
            WRITE("if (self hasnt animate) jump %s;\n", failure_label);
        if ((bp == a_contains_b_predicate) ||
            (bp == a_supports_b_predicate) ||
            (bp == a_has_b_predicate) ||
            (bp == a_wears_b_predicate) ||
            (bp == a_carries_b_predicate)) {
            WRITE("objectloop (rv in self) {\n"); INDENT;
            if (bp == a_carries_b_predicate)
                WRITE("if (rv has worn) continue;\n");

The function gtok_compile is called from 13/gl.

Noun Filter Tokens 13/nft

Purpose

Filters are used to require nouns to have specific kinds or attributes, or to have specific scoping rules: they correspond to Inform 6's `noun=Routine` and `scope=Routine` tokens. Though these are quite different concepts in I6, their common handling seems natural in I7.

13/nft.§2 Access via ID; §3 Compiling everything

Template interpreter commands

```
3   {-callv:compile_filters}
```

Definitions

```
typedef struct noun_filter_token {
    struct specification *the_filter;
    int global_scope_flag;
    MEMORY_MANAGEMENT
} noun_filter_token;
```

The structure noun_filter_token is private to this section.

---

§**1.** There are only three things we can do with these: create them, compile their names (used as I6 tokens), and compile their routines.

```
noun_filter_token *nft_new(specification *spec, int global_scope) {
    noun_filter_token *nft = CREATE(noun_filter_token);
    nft->the_filter = spec;
    nft->global_scope_flag = global_scope;
    return nft;
}
void nft_compile_routine_name(OUTPUT_STREAM, noun_filter_token *nft) {
    if (nft->global_scope_flag)
        WRITE("Scope_Filter_%d", nft->allocation_id);
    else
        WRITE("Noun_Filter_%d", nft->allocation_id);
}
void nft_compile_routine(OUTPUT_STREAM, noun_filter_token *nft) {
    specification *noun_var = new_QUANTITY_spec(I6_noun_quantity);
    WRITE("[ ");
    nft_compile_routine_name(OUT, nft);
    if (nft->global_scope_flag) {
        WRITE(" obj o2;\n"); INDENT;
        WRITE("switch (scope_stage) {\n"); INDENT;
        WRITE("1: rfalse;\n");
        WRITE("2: obj=noun;\n");
        WRITE("suppress_scope_loops = true;\n");
        WRITE("objectloop(noun ofclass Object && (");
        compile_test_if_var_matches_description(OUT, noun_var, nft->the_filter);
```

```
        WRITE(")) {\n"); INDENT;
        WRITE("o2 = noun; noun = obj; PlaceInScope(o2, true); noun = o2;\n");
        OUTDENT; WRITE("}\n");
        WRITE("noun=obj;\n");
        WRITE("suppress_scope_loops = false;\n");
        WRITE("3: nextbest_etype = NOTINCONTEXT_PE; return -1;\n");
        OUTDENT; WRITE("}\n");
        OUTDENT; WRITE("];\n");
    } else {
        WRITE(" x;\n"); INDENT;
        WRITE("x=noun;\n");
        WRITE("return ");
        if (spec_get_proposition(nft->the_filter)) {
            prop_type_check(spec_get_proposition(nft->the_filter), tc_no_problem_reporting());
            compile_test_of_proposition(
                OUT, noun_var, spec_get_proposition(nft->the_filter));
        } else
            compile_test_if_var_matches_description(
                OUT, noun_var, nft->the_filter);
        WRITE(";\n");
        OUTDENT; WRITE("];\n");
    }
}
```

§**2. Access via ID.** For now, though, these are perhaps strangely accessed by ID number. (Because the `parse_node` structure can't conveniently be annotated with pointers, that's why.)

```
int nft_new_id(specification *spec, int global_scope) {
    return nft_new(spec, global_scope)->allocation_id;
}
void nft_compile_by_id(OUTPUT_STREAM, int id, int code_mode) {
    noun_filter_token *nft;
    LOOP_OVER(nft, noun_filter_token)
        if (nft->allocation_id == id) {
            if (code_mode) {                                  arguments to the I6 routine ParseTokenStopped
                if (nft->global_scope_flag) WRITE("SCOPE_TT, ");
                else WRITE("ROUTINE_FILTER_TT, ");
            } else {                                                  tokens for use in Verb directives
                if (nft->global_scope_flag) WRITE("scope=");
                else WRITE("noun=");
            }
            nft_compile_routine_name(OUT, nft);
        }
}
```

The function nft_new_id is called from 13/gtok.

The function nft_compile_by_id is called from 13/gtok.

§3. Compiling everything. Having referred to these filter routines, we need to compile them.

```
void compile_filters(OUTPUT_STREAM) {
    noun_filter_token *nft;
    LOOP_OVER(nft, noun_filter_token)
        nft_compile_routine(OUT, nft);
}
```

The function compile_filters is invoked by a command in a `.i6t` template file.

Tokens Parsing Values 13/gprv

Purpose

In the argot of Inform 6, GPR stands for General Parsing Routine, and I7 makes heavy use of GPR tokens to achieve its ends. This section is where the necessary I6 routines are compiled.

Template interpreter commands

```
0   {-callv:compile_number_grammar}
0   {-callv:compile_time_grammar}
0   {-callv:compile_truth_state_grammar}
0   {-callv:compile_type_gprs}
```

```

                            WRITE(") jump Failed_%d;\n", next_label);
                        }
                        WRITE("parsed_number = ");
                        compile_quantity_name(OUT, q);
                        WRITE("; return GPR_NUMBER;\n");
                        WRITE(".Failed_%d;\n", next_label++);
                    }
            }
        }
        WRITE("return GPR_FAIL;\n");
        OUTDENT; WRITE("];\n");
    }
}

void gprv_compile(OUTPUT_STREAM, kind_of_value *kov) {
    WRITE("Designed_Type_GPR_%d", kov_I6_ID(kov));
}
```

The function compile_number_grammar is invoked by a command in a `.i6t` template file.

The function compile_time_grammar is invoked by a command in a `.i6t` template file.

The function compile_truth_state_grammar is invoked by a command in a `.i6t` template file.

The function compile_type_gprs is invoked by a command in a `.i6t` template file.

The function gprv_compile is called from 13/gtok and 13/gpr.

General Parsing Routines 13/gpr

Purpose

To compile I6 general parsing routines (GPRs) and/or `parse_name` properties as required by the I7 grammar.

§**1.** In this section we compile GPRs, routines to handle `Consult`-like text, and also `parse_name` routines, which as we shall see come in two different forms. These routines share a basic protocol for dealing with the I6 library, which makes things considerably easier. In each case, the routine is compiled as a head and then, subsequently, a tail: the user of the routines is expected to compile the actual grammar in between the two. Every head must be followed by exactly one tail of the same sort; every tail must be preceded by exactly one head of the same sort; but code to parse at `wn` may be placed in between.

The GPRs compiled to parse literal values of given kinds of values (for instance, exotic verbal forms of numbers, or verbal names of the constants for new kinds of value, or literal patterns) are not compiled here: they are in Tokens Parsing Values.

§**2. GPRs used as tokens.** To parse a token, we match as much as possible from word number `wn`.

```
void gpr_compile_gpr_head(OUTPUT_STREAM, int id) {
    WRITE("[ GPR_Line_%d\n", id); INDENT;
    WRITE("original_wn  ! first word of text parsed\n");
    WRITE("group_wn  ! first word matched against A/B/C/... disjunction\n");
    WRITE("w  ! for use by individual grammar lines\n");
    WRITE("rv  ! for use by individual grammar lines\n");
    WRITE(";\n");
    WRITE("original_wn = wn; rv = GPR_PREPOSITION;\n");
}
void gpr_compile_gpr_tail(OUTPUT_STREAM) {
    WRITE("return GPR_FAIL;\n");
    OUTDENT; WRITE("];\n\n");
}
void gpr_compile_prn_pr_head(OUTPUT_STREAM, property_name *prn) {
    WRITE("[ PRN_PN_%d\n", prn->allocation_id); INDENT;
    WRITE("original_wn  ! first word of text parsed\n");
    WRITE("group_wn  ! first word matched against A/B/C/... disjunction\n");
    WRITE("w  ! for use by individual grammar lines\n");
    WRITE("rv  ! for use by individual grammar lines\n");
    WRITE(";\n");
    WRITE("original_wn = wn; rv = GPR_PREPOSITION;\n");
}
void gpr_compile_prn_pr_tail(OUTPUT_STREAM, property_name *prn) {
    WRITE("return GPR_FAIL;\n");
    OUTDENT; WRITE("];\n\n");
}
```

The function gpr_compile_gpr_head is called from 13/gv.

The function gpr_compile_gpr_tail is called from 13/gv.

The function gpr_compile_prn_pr_head is called from 13/gv.

The function gpr_compile_prn_pr_tail is called from 13/gv.

§**3. Consult routines.** These are used to parse an explicit range of words (such as traditionally found in the CONSULT command) at run time, and they are *not* I6 grammar tokens, and do *not* appear in `Verb` declarations: otherwise, such routines are very similar to GPRs.

First, we need to look after a pointer to the GV used to hold the grammar being matched against the snippet of words.

```
grammar_verb *consultation_gv = NULL;                                    used only in routines below
grammar_verb *gpr_get_consultation_gv(void) {
    if (consultation_gv == NULL) consultation_gv = gv_consultation_new();
    return consultation_gv;
}
void gpr_prepare_consultation_gv(void) {
    consultation_gv = NULL;
}
void gpr_print_consultation_gv_name(OUTPUT_STREAM) {
    if (consultation_gv)
        WRITE("Consult_Grammar_%d", consultation_gv->allocation_id);
}
```

The function gpr_get_consultation_gv is called from 13/tfg.
The function gpr_prepare_consultation_gv is called from 13/tfg.
The function gpr_print_consultation_gv_name is called from 13/tfg.

§**4.** We also, at another time, need to compile the routine being named. There are no timing difficulties here: the routine's name is used in the context of an I6 constant rather than in a `Verb` declaration, so no predeclaration is needed.

```
void gpr_compile_consult_head(OUTPUT_STREAM, int id) {
    WRITE("[ Consult_Grammar_%d\n", id); INDENT;
    WRITE("range_from  ! call parameter: word number of snippet start\n");
    WRITE("range_words  ! call parameter: snippet length\n");
    WRITE("original_wn  ! first word of text parsed\n");
    WRITE("group_wn  ! first word matched against A/B/C/... disjunction\n");
    WRITE("w  ! for use by individual grammar lines\n");
    WRITE("rv  ! for use by individual grammar lines\n");
    WRITE(";\n");
    WRITE("wn = range_from; original_wn = wn; rv = GPR_PREPOSITION;\n");
}
void gpr_compile_consult_tail(OUTPUT_STREAM) {
    WRITE("return GPR_FAIL;\n");
    OUTDENT; WRITE("];\n\n");
}
```

The function gpr_compile_consult_head is called from 13/gv.
The function gpr_compile_consult_tail is called from 13/gv.

§**5. Parse name properties.** One of the major services provided by I7, as compared with I6, is that it automatically compiles what would otherwise be laborious `parse_name` routines for its objects. This is messy, because the underlying I6 syntax is messy. The significant complication is that the I6 parser makes two quite different uses of `parse_name`: not just for parsing names, but also for determining whether two objects are visually distinguishable, something it needs to know in order to make plural objects work properly.

If an object has any actual grammar attached, say a collection of grammar lines belonging to GV3, we will compile the `parse_name` as an independent I6 routine with a name like `Parse_Name_GV3`. If not, a `parse_name` may still be needed, because of the distinguishability problem: if so then we will simply compile a `parse_name` routine inline, in the usual I6 way.

```
void gpr_compile_parse_name_property(OUTPUT_STREAM, world_object *wo,
    grammar_verb *gv) {
    if (gv_is_empty(gv) == FALSE)
        WRITE(" with parse_name Parse_Name_GV%d\n", gv->allocation_id);
    else
        if (gpr_compile_parse_name_head(OUT, wo, NULL)) {
            gpr_compile_parse_name_tail(OUT);
            WRITE(",\n");
        }
}
```

The function gpr_compile_parse_name_property is called from 9/cot.

§**6.** The following routine produces one of three outcomes: either (i) the head of an I6 declaration of a free-standing routine to be used as a `parse_name` property, or (ii) the head of an I6 inline declaration of a `parse_name` property as a `with` clause for an `Object` directive, or

(iii) the empty output, in happy cases where neither parsing nor distinguishability need to be investigated. The routine returns a flag indicating if a tail need be compiled (i.e., in cases (i) or (ii) but not (iii)).

In cases (i) and (ii), the head is immediately followed by code which looks at the names of visible properties. Recall that a visible property is one which can be used to describe an object: for instance, if colour is a visible property of a car, then it can be called "green car" if and only if the current value of the colour of the car is "green", and so forth. In all such cases, we need to parse the text to look for the name of the current value.

But if a property can be used as part of the name, then it follows that two objects with the same grammar (and name words) cease to be indistinguishable when their values for this property differ. For instance, given two otherwise identical cars which can only be called "car", we can distinguish them with the names "red car" and "green car" if one is red and the other green. The parser needs to know this. It calls the `parse_name` routine with an I6 global called `parser_action` set to `##TheSame` in such a case, and we can return 0 to make no decision or `-2` to say that they are different.

Note that the parser checks this only if two or more objects share the same `parse_name` routine: which will in I7 happen only if they each inherit it from the I6 class of a common kind. Because `parse_name` is not additive in I6, this can only occur if the objects, and any intervening classes for intervening kinds, define no `parse_name` of their own.

We will test distinguishability only for kinds which have permissions for visible properties: kinds because no other `parse_name` values can ever be duplicated in instance objects, and visible properties because these are the only ways to tell apart instances which have no grammar of their own. (If either had grammar of its own, it would also have its own `parse_name` routine.) For all other kinds, we return a make-no-decision value in response to a `##TheSame` request: this ensures that the I6 parser looks at the `name` properties of the objects instead, and in the absence of either I7-level grammar lines or visible properties, that will be the correct decision.

```
int gpr_compile_parse_name_head(OUTPUT_STREAM, world_object *wo, grammar_verb *gv) {
    int allow_inheritance = FALSE, test_distinguishability = FALSE,
```

```
        sometimes_has_visible_properties = FALSE, use_two_passes = TRUE;
    if (wo == NULL) internal_error("compiling parse_name head for null wo");
    sometimes_has_visible_properties = pr_any_visible_to_wo(wo, TRUE);
    if (gv) {
        top_of_head(OUT, gv->allocation_id, use_two_passes);
        allow_inheritance = TRUE;
        if ((wo->kind_flag) && (sometimes_has_visible_properties == FALSE))
            WRITE("if (parser_action == ##TheSame) return 0;\n");
    } else {
        if (pr_any_visible_to_wo(wo, FALSE) == FALSE) return FALSE;
        top_of_head(OUT, -1, use_two_passes);
    }
    if (wo->kind_flag) test_distinguishability = TRUE;
    consider_visible_properties(OUT, wo, allow_inheritance, test_distinguishability);
    return TRUE;
}
```

The function gpr_compile_parse_name_head is called from 13/gv.

§**7.** Each head is followed by a tail before the next head: there is no recursion. Therefore it is safe to record a state when compiling the head, and to recover it when compiling the tail.

The two-pass form of the routine is used in cases where there are visible properties. The two passes check the possible patterns:

(1) (words in `name` property) (visible property names) (longer grammar)

(2) (visible property names) (longer grammar) (words in `name` property)

The longer match is taken: but note that a match of visible property names alone is rejected unless at least one property has been declared sufficient to identify the object all by itself. Longer grammar means grammar lines containing 2 or more words, since all single-fixed-word grammar lines for GVs destined to be `parse_name`s is stripped out and converted into the `name` property.

There are clearly other possibilities and the above system is something of a pragmatic compromise (in that to check other cases would be slower and more complex). I suspect we will return to this.

```
int this_parse_name_is_two_pass = NOT_APPLICABLE;
void top_of_head(OUTPUT_STREAM, int id, int two_pass) {
    if (id >= 0) WRITE("[ Parse_Name_GV%d\n", id);
    else WRITE("with parse_name [\n");
    INDENT;
    this_parse_name_is_two_pass = two_pass;
    WRITE("original_wn  ! first word of text parsed\n");
    WRITE("group_wn  ! first word matched against A/B/C/... disjunction\n");
    WRITE("try_from_wn  ! position to try matching from\n");
    WRITE("n  ! number of words matched\n");
    WRITE("f  ! flag: sufficiently good match found to justify success\n");
    WRITE("w  ! for use by individual grammar lines\n");
    WRITE("rv  ! for use by individual grammar lines\n");
    WRITE("g  ! temporary: success flag for parsing visibles\n");
    WRITE("ss  ! temporary: saves 'self' in distinguishing visibles\n");
    WRITE("spn  ! temporary: saves 'parsed_number' in parsing visibles\n");
    if (this_parse_name_is_two_pass) {
        WRITE("pass  ! pass counter (1 or 2)\n");
```

```
        WRITE("pass1_n  ! value of n recorded during pass 1\n");
        WRITE(";\n");
        WRITE("if (parser_trace >= 3) print \"Two-pass parse_name called^\";\n");
        WRITE("original_wn = wn;\n");
        WRITE("for (pass = 1: pass <= 2: pass++) {\n"); INDENT;
        WRITE("wn = original_wn;\n");
        WRITE("try_from_wn = wn; f = false; n = 0;\n");
        WRITE("! On pass 1 only, advance wn past name property words\n");
        WRITE("! (but do not do this for ##TheSame, when wn is undefined)\n");
        WRITE("if ((parser_action ~= ##TheSame) && (pass == 1)) {\n"); INDENT;
        WRITE("while (WordInProperty(NextWordStopped(), self, name)) f = true;\n");
        WRITE("wn--; try_from_wn = wn;\n");
        OUTDENT; WRITE("}\n");
    } else {
        WRITE(";\n");
        WRITE("original_wn = wn;\n");
        WRITE("try_from_wn = wn;\n");
    }
}
```

§**8.** The head and tail routines can only be understood by knowing that the following code is used to reset the grammar-line parser after each failure of a GL to parse.

```
void gpr_after_gl_failed(OUTPUT_STREAM, int label, int pluralised) {
    if (pluralised) WRITE("parser_action = ##PluralFound;\n");
    WRITE("try_from_wn = wn; f = true;\n");
    WRITE(".Fail_%d; wn = try_from_wn;\n", label);
}
```

The function gpr_after_gl_failed is called from 13/gl.

§**9.** The interesting point about the tail of the `parse_name` routine is that it ends on the `]` "close routine" character, in mid-source line. This is because the routine may be being used inside an `Object` directive, and would therefore need to be followed by a comma, or in free-standing I6 code, in which case it would need to be followed by a semi-colon.

```
void gpr_compile_parse_name_tail(OUTPUT_STREAM) {
    if (this_parse_name_is_two_pass == NOT_APPLICABLE)
        internal_error("synchrony broken between parse_name head and tail");
    if (this_parse_name_is_two_pass == TRUE) {
        WRITE("! On pass 2 only, match name property words at end\n");
        WRITE("if (pass == 2)\n");
    }
    WRITE("while (WordInProperty(NextWordStopped(), self, name)) n++;\n");
    WRITE("if ((f) || (n>0)) n = n + try_from_wn - original_wn;\n");
    if (this_parse_name_is_two_pass == TRUE) {
        WRITE("if (pass == 1) pass1_n = n;\n");
        OUTDENT; WRITE("} ! End of pass loop\n");
        WRITE("if (parser_trace >= 3)\n"); INDENT;
        WRITE("print \"Pass 1: \", pass1_n, \" Pass 2: \", n, \"^\";\n");
        OUTDENT;
        WRITE("if (pass1_n > n) n = pass1_n;\n");
    }
```

```
    WRITE("wn = original_wn + n;\n");
    WRITE("if (n == 0) return -1;\n");
    WRITE("DetectPluralWord(original_wn, n);\n");
    WRITE("return n;\n");
    OUTDENT; WRITE("]");
    this_parse_name_is_two_pass = NOT_APPLICABLE;
}
```

The function gpr_compile_parse_name_tail is called from 13/gv.

§**10.** We generate code suitable for inclusion in a `parse_name` routine which either tests distinguishability then parses, or else just parses, the visible properties of a given world object (which may be a kind). Sometimes we allow visibility to be inherited from a permission given to a kind, sometimes we require that the permission be given to this specific object.

```
void consider_visible_properties(OUTPUT_STREAM, world_object *wo,
    int allow_inheritance, int test_distinguishability) {
    int phase = 2;
    if (test_distinguishability) phase = 1;
    for (; phase<=2; phase++) {
        property_name *pr;
        start_considering_visible_properties(OUT, phase);
        LOOP_OVER(pr, property_name) {
            property_permission *pp;
            for (pp = prn_permission_list(pr); pp; pp = pp->next)
                if (pp_visible_to_wo(pp, wo, allow_inheritance))
                    consider_visible_property(OUT, wo, pr, pp, phase);
        }
        finish_considering_visible_properties(OUT, phase);
    }
}
```

§**11. Common handling for distinguishing and parsing.** The top-level considering routines parcel up work and hand it over to the distinguishing routines if `phase` is 1, and the parsing routines if `phase` is 2. Note that if there are no sometimes-visible-properties then the correct behaviour is to call none of the routines below this level, and to compile nothing to the file.

```
int visible_properties_code_written = FALSE;                    persistent state used only here
void start_considering_visible_properties(OUTPUT_STREAM, int phase) {
    visible_properties_code_written = FALSE;
}
void consider_visible_property(OUTPUT_STREAM, world_object *wo,
    property_name *pr, property_permission *pp, int phase) {
    int conditional_vis = FALSE;
    specification *spec;
    if (visible_properties_code_written == FALSE) {
        visible_properties_code_written = TRUE;
        if (phase == 1)
            begin_distinguishing_visible_properties(OUT);
        else
            begin_parsing_visible_properties(OUT);
    }
```

```
    spec = pp_get_visibility_condition(pp);
    if (spec) {
        conditional_vis = TRUE;
        TEMPORARY_STREAM;
        LOG("Understand when condition: $S\n", spec);
        spec_compile(TEMP, spec);
        if (phase == 1)
            test_distinguish_visible_property(OUT, TEMP);
        else
            test_parse_visible_property(OUT, TEMP);
        CLOSE_TEMPORARY_STREAM;
    }
    if (phase == 1)
        distinguish_visible_property(OUT, pr);
    else
        parse_visible_property(OUT, wo, pr, pp_visibility_level(pp));
    if (conditional_vis) { OUTDENT; WRITE("}\n"); }
}
void finish_considering_visible_properties(OUTPUT_STREAM, int phase) {
    if (visible_properties_code_written) {
        if (phase == 1)
            finish_distinguishing_visible_properties(OUT);
        else
            finish_parsing_visible_properties(OUT);
    }
}
```

§**12. Distinguishing visible properties.** We distinguish two objects P1 and P2 based on the following criteria:

(i) if any property is currently visible for P1 but not P2 or vice versa, then they are distinguishable; (ii) if any value property is visible but P1 and P2 have different values for it, then they are distinguishable;

(iii) if any either/or property is visible but P1 has it and P2 hasn't, or vice versa, then they are distinguishable; and otherwise we revert to the I6 parser's standard algorithm, which looks at the `name` property.

```
void begin_distinguishing_visible_properties(OUTPUT_STREAM) {
    WRITE("if (parser_action==##TheSame) {\n"); INDENT;
    WRITE("if (parser_trace >= 4) print \"p1, p2 = \", parser_one, \", \", parser_two, \"^\";\n");
    WRITE("ss = self;\n");
}
void test_distinguish_visible_property(OUTPUT_STREAM, STREAM *COND) {
    WRITE("self = parser_one; f = (");
    STREAM_COPY(OUT, COND);
    WRITE(");\n");
    WRITE("self = parser_two; g = (");
    STREAM_COPY(OUT, COND);
    WRITE(");\n");
    WRITE("if (f ~= g) return -2;\n");
    WRITE("if (f) {\n"); INDENT;
}
void distinguish_visible_property(OUTPUT_STREAM, property_name *prn) {
    if (prn_is_either_or(prn)) {
```

```
        WRITE("if ((parser_one "); compile_has_property(OUT, prn);
        WRITE(") && (~~(parser_two "); compile_has_property(OUT, prn);
        WRITE("))) return -2;\n");
        WRITE("if ((parser_two "); compile_has_property(OUT, prn);
        WRITE(") && (~~(parser_one "); compile_has_property(OUT, prn);
        WRITE("))) return -2;\n");
    } else {
        kind_of_value *kov = prn_get_kind_of_value(prn);
        char *distinguisher = kov_get_distinguisher(kov);
        if (distinguisher) {
            WRITE("if (%s(parser_one.%s, parser_two.%s)) return -2;\n",
                distinguisher, prn_get_i6_identifier(prn), prn_get_i6_identifier(prn));
        } else {
            WRITE("if (parser_one.%s ~= parser_two.%s) return -2;\n",
                prn_get_i6_identifier(prn), prn_get_i6_identifier(prn));
        }
    }
}
void finish_distinguishing_visible_properties(OUTPUT_STREAM) {
    WRITE("self = ss; return 0;\n");
    OUTDENT; WRITE("}\n");
}
```

§**13. Parsing visible properties.** Here, unlike in distinguishing visible properties, it is unambiguous that `self` refers to the object being parsed: there is therefore no need to alter the value of `self` to make any visibility condition work correctly.

```
void begin_parsing_visible_properties(OUTPUT_STREAM) {
    WRITE("! Match any number of visible property values\n");
    WRITE("try_from_wn = wn; g = true; while (g) {\n"); INDENT;
    WRITE("g = false;\n");
}
void test_parse_visible_property(OUTPUT_STREAM, STREAM *COND) {
    WRITE("if (");
    STREAM_COPY(OUT, COND);
    WRITE(") {\n"); INDENT;
}
int unique_pvp_counter = 0;
void parse_visible_property(OUTPUT_STREAM,
    world_object *wo, property_name *prn, int visibility_level) {
    if (prn_is_either_or(prn)) {
        property_name *prnbar;
        parse_visible_either_or(OUT, prn, visibility_level, unique_pvp_counter);
        prnbar = prn_either_or_get_negation(prn);
        if (prnbar)
            parse_visible_either_or(OUT, prnbar, visibility_level, unique_pvp_counter);
        WRITE(".pvp_pass_L_%d;\n", unique_pvp_counter++);
    } else {
        kind_of_value *kov = prn_get_kind_of_value(prn);
        char *recog_gpr;
        pvp_test_begins(OUT);
```

```
        WRITE("spn = parsed_number; if ((");
        recog_gpr = kov_get_recognition_only_GPR(kov);
        if (recog_gpr) {
            WRITE("%s(self.%s) == GPR_PREPOSITION))",

Test Scripts 13/test

Purpose

A rudimentary but useful testing system built in to IF produced by Inform, allowing short sequences of commands to be concisely noted in the source text and tried out in the Inform application using the TEST command.

Template interpreter commands

```
0   {-callv:write_test_text}
0   {-callv:compile_test_switch}
0   {-callv:compile_test_printout}
1   {-routine:InternalTestCases}
```

Definitions

¶1. Test scenarios are used for the "TEST" command: they consist of a string of commands in text format, with a few stipulations on place and possessions attached.

```
define MAX_LENGTH_OF_SCRIPT 10000                    including length byte, so the max no of chars is one less
define MAX_LENGTH_OF_COMMAND 100                     any single command must be this long or shorter
define MAX_POSSESSIONS_PER_SCENARIO 16

typedef struct test_scenario {
    int name_wn;                                     word number of single word identifying the test
    char text_of_script[MAX_LENGTH_OF_SCRIPT];
    int commands_wn;                                 word number of quoted text of command sequence
    struct world_object *place;                      room we need to be in to perform test
    int no_possessions;                              number of required possessions of player
    struct world_object *possessions[MAX_POSSESSIONS_PER_SCENARIO];   what they are
    struct parse_node *sentence_test_declared_at;
    MEMORY_MANAGEMENT
} test_scenario;
```

The structure test_scenario is private to this section.

¶2.

```
define HEADLINE_INTT 1
define SENTENCE_INTT 2
define DESCRIPTION_INTT 3
define DIMENSIONS_INTT 4
define EVALUATION_INTT 5
define EQUATION_INTT 6
```

```
typedef struct internal_test_case {
    int itc_code;                                   one of the above *_INTT values

14 Program Control

`14/main`: *Main Routine.w* As with all C programs, NI begins execution in the `main` routine, reading command-line arguments to modify its behaviour. This is where we define `main`.

`14/i6t`: *I6 Template Interpreter.w* Inform 6 meta-language is the language used by template files (with extension `.i6t`). It is not itself I6 code, but a list of instructions for making I6 code: most of the content is to be copied over verbatim, but certain escape sequences cause NI to insert more elaborate material, or to do something active. The entire top-level logic of NI is carried out by interpreting the `Main.i6t` file in this way.

Main Routine 14/main

Purpose

As with all C programs, NI begins execution in the `main` routine, reading command-line arguments to modify its behaviour. This is where we define `main`.

Definitions

¶1. From the local environment, we also extract the time at which NI is running. We need this to fill in the correct date of creation in the bibliographic data for a work, for instance.

```

---

§**1.** As with all C programs, NI begins execution in the `main` routine, which takes command-line arguments with the standard parameters `argc` and `argv`.

In this program, `main` consists only of command-line processing and the very minimum setup necessary to begin an I6 inclusion before handing over to the meta-language interpreter to run through `Main.i6t`.

NI returns only two possible values to the shell, either here or via `exit(1)` in the case of fatal errors: 0 if it completed its run with no errors, 1 if errors were produced.

```
int main(int argc, char *argv[]) {
    int i, a = 1, source_specified = FALSE;
    char *val;
    STREAM_WRITE(STDOUT, "%s build %s has started.\n", NI_VERSION, NI_BUILD);
    STREAM_FLUSH(STDOUT);
    what_day_is_it();
    bundle_name = NULL;
    crash_on_internal_errors = FALSE;
    crash_on_all_errors = FALSE;
    story_filename_extension = NULL;
    make_pathname_of_extensions();
    if (argc == a) return 0;
    while (a < argc) {
        char *option = argv[a];
        if ((option[0] == '-') && (option[1] == '-')) option++;
        if (strcmp("-log", option) == 0) {
            Non-functional for now
            a++; continue;
        }
        if (strlen(option) > 5) {
            if ((option[0] == '-') && (option[1] == 'l') && (option[2] == 'o') &&
                (option[3] == 'g') && (option[4] == '=')) {
                set_dl_from_command_line(option+5);
                a++; continue;
            }
        }
        if (strcmp("-rng", option) == 0) {
            fix_rng_at_start_of_play = TRUE;
```

```
        rng_seed_at_start_of_play = -16339;
        a++; continue;
    }
    if ((val = cli_pair("-extension", option)) != 0) {
        story_filename_extension = val;
        a++; continue;
    }
    if (strcmp("-release", option) == 0) {
        for_release = TRUE;
        a++; continue;
    }
    if (strcmp("-noprogress", option) == 0) {
        show_progress_indicator = FALSE;
        a++; continue;
    }
    if (strcmp("-census", option) == 0) {
        census_mode = TRUE;
        a++; continue;
    }
    if (strcmp("-sigils", option) == 0) {
        echo_problem_message_sigils = TRUE;
        a++; continue;
    }
    if (strcmp("-gdb", option) == 0) {
        crash_on_internal_errors = TRUE;
        a++; continue;
    }
    if (strcmp("-gdball", option) == 0) {
        crash_on_all_errors = TRUE;
        a++; continue;
    }
    if (strcmp("-noindex", option) == 0) {

    }
    if (strcmp("-package", option) == 0) {
        source_specified = TRUE;
        bundle_name = argv[a+1];
        a = a+2; continue;
    }
    if (strcmp("-rules", option) == 0) {
        strcpy(pathname_of_built_in_extensions, argv[a+1]);
        a = a+2; continue;
    }
    if (source_specified) {
        fatal_error("Unknown parameter at the command line");
    } else {
        source_specified = TRUE;
        source_text_file = argv[a]; a++;
    }
}
```

```
    set_VM_identifier(story_filename_extension);
    if ((census_mode == FALSE) && (source_specified == FALSE))
        fatal_error("Except in census mode, source text must be supplied");
    if ((census_mode) && (source_specified))
        fatal_error("In census mode, no source text may be supplied");
    open_log_files();
    LOG("NI called as: ");
    for (i=0; i<argc; i++) LOG("%s ", argv[i]);
    LOG("\n");
    interpret_I6T_file(NULL, NULL, "Main.i6t", -1);
    LOG("Total of %d files written as streams.", total_file_writes);
    close_log_files();
    STREAM_WRITE(STDOUT, "%s has finished.\n", NI_VERSION);
    STREAM_FLUSH(STDOUT);
    if (problem_count > 0) return 1; return 0;
}
void what_day_is_it(void) {
    time_t right_now = time(NULL);
    long long int rni = (long long int) right_now;
    if (rni < 0) right_now = (time_t) 0;
    the_present = localtime(&right_now);
}
char *cli_pair(char *wanted, char *got) {
    int i;
    if (strlen(wanted)+1 >= strlen(got)) return NULL;
    for (i=0; wanted[i]; i++) if (wanted[i] != got[i]) return NULL;
    if (got[i] != '=') return NULL;
    return got+i+1;
}
```

The function main is where execution begins.

I6 Template Interpreter 14/i6t

Purpose

Inform 6 meta-language is the language used by template files (with extension `.i6t`). It is not itself I6 code, but a list of instructions for making I6 code: most of the content is to be copied over verbatim, but certain escape sequences cause NI to insert more elaborate material, or to do something active. The entire top-level logic of NI is carried out by interpreting the `Main.i6t` file in this way.

Template interpreter commands

```
32    {-callv:report_unacted_upon_interventions}
33    {-callv:compile_build_number}
```

Definitions

¶1. The user (or an extension used by the user) is allowed to register gobbets of I6T code to be used before, instead of, or after any whole segment or named part of a segment of the template layer: the following structure holds such a request.

```
typedef struct I6T_intervention {
    int intervention_stage;                                  −1 for before, 0 for instead, 1 for after
    char *segment_name;
    char *part_name;                                         or NULL to mean the entire segment
    char *I6T_matter;                                        to be used at the given position, or NULL
    char *alternative_segment;                               to be used at the given position, or NULL
    int segment_found;                                       did the segment name match one actually read?
    int part_found;                                          did the part name?
    struct parse_node *where_intervention_requested;         at what sentence?
    MEMORY_MANAGEMENT
} I6T_intervention;
```

The structure I6T_intervention is private to this section.

¶2. The following flag is set by the `-noindex` command line option.

```
int do_not_generate_index = FALSE;
```

---

§**1. Syntax of I6T files.** The syntax of these files has been designed so that a valid I6T file is also a valid Inweb section file. This means that no tangling is required to make the I6T files: they can be, and indeed are, simply copied verbatim from Appendix B of the source web.

Formally, an I6T file consists of a preamble followed by one or more parts. The preamble takes the form:

```
B/name: Longer Form of Name.

@Purpose: ...

@-------------------------------------------------------------------------------
```

(for some number of dashes). Each part begins with a heading line in the form

```
@p Title.
```

At some point during the part, a heading line

```
@c
```

introduces the code of the part. When NI interprets an I6T file, it ignores the preamble and the material in every part before the `@c` heading: these are commentary.

It actually doesn't matter if a template file contains lines longer than this, so long as they do not occur inside `{-lines:...}` and `{-endlines}`, and so long as no individual braced command `{-...}` exceeds this length.

```
define MAX_I6T_LINE_LENGTH 1024
```

§**2.** We can regard the whole NI program as basically a filter: it copies its input, the `Main.i6t` template file, directly into its output, but making certain replacements along the way.

The code portions of `.i6t` files are basically written in I6, but with a special escape syntax:

```
{-command:argument}
```

tells NI to act *immediately* on the I6T command given, with the argument supplied. One of these commands is special:

```
{-lines:commandname}
```

tells NI that all subsequent lines in the I6T file, up to the next `{-endlines}`, are to be read as a series of arguments for the `commandname` command. Thus,

```
{-lines:admire}
Jackson Pollock
Paul Klee
Wassily Kandinsky
{-endlines}
```

is a shorthand form for:

```
{-admire:Jackson Pollock}{-admire:Paul Klee}{-admire:Wassily Kandinsky}
```

The following comment syntax is useful mainly for commenting out commands:

```
{-! Something very clever happens next.}
```

The commands all either instruct NI to do something (say, traverse the parse tree and convert its assertions to inferences) but output nothing, or else to compile some I6 code to the output. There are no control structures, no variables: I6T commands do not amount to a programming language.

§**3.** I7 expressions can be included in I6T code exactly as in inline invocation definitions: thus

```
Constant FROG_CLASS = (+ pond-dwelling amphibian +);
```

will expand "pond-dwelling amphibian" into the I6 translation of the kind of object with this name. Because of this syntax, one has to watch out for I6 code like so:

```
if (++counter_of_some_kind > 0) ...
```

which can trigger an unwanted `(+`.

§**4.** It is not quite true that the following routine acts as a filter from input to output, because:

(i) It skips the preamble and the commentary portion of each part in the input.

(ii) It has an `active` mode, outside of which it ignores most commands and copies no output – it begins in active mode and leaves it only when NI issues problem messages, so that subsequent commands almost certainly cannot safely be used. In a successful compilation run, the interpreter remains in active mode throughout. Otherwise, generally speaking, it goes into passive mode as soon as an I6T command has resulted in Problem messages, and then in stays in passive mode until the output file is closed again; then it goes back into active mode to carry out some shutting-down-gracefully steps.

(iii) The output file is not always open. In fact, it starts unopened (and with `of` set to null); two of the I6T commands open and close it. When the file isn't open, no output can be written, but I6T commands telling NI to do something can still take effect: in fact, the `Main.i6t` file begins with dozens of I6T commands before the output file is opened, and concludes with a couple of dozen more after it has been closed. For almost all of the I6T files, however, the output file is open throughout; the other exception being `Types.i6t`, a long run of commands to create NI's data types, which is interpreted before the output file is opened.

(iv) It can abort, cleanly exiting NI when it does so, if a global flag is set as a result of work done by one of its commands. In fact, this is used only to exit NI early after performing an extension census when called with the command line option `-census`, and can never happen on a compilation run, whatever problems or disasters may occur.

§**5.** The I6T interpreter is a single routine which implements the description above:

```
define MAX_I6T_COMMAND_LENGTH 128

void interpret_I6T_file(OUTPUT_STREAM, char *sf, char *segment_name, int N_escape) {
    FILE *Input_File = NULL;
    char default_command[MAX_I6T_COMMAND_LENGTH]; default_command[0] = 0;
    char heading_name[MAX_I6T_LINE_LENGTH+1]; heading_name[0] = 0;
    int active = TRUE, closed = FALSE, indexing = FALSE, skip_part = FALSE, comment = TRUE;
    int no_phases = 0, col = 1, cr, sfp = 0;
    if (segment_name) I6T_file_intervene(OUT, -1, segment_name, NULL);
    if ((segment_name) && (I6T_file_intervene(OUT, 0, segment_name, NULL))) goto OmitFile;
    if (segment_name) {
        ⟨Open the I6 template file 6⟩;
        comment = TRUE;
    } else comment = FALSE;
    do {
        ⟨Read next character from I6T stream 9⟩;
        NewCharacter: if (cr == EOF) break;
        char I6T_buffer[MAX_I6T_LINE_LENGTH+1];                    storage for an I6T command
        char *command = "", *argument = "";
        if (abort_I6T_interpreter) {                               in effect, if NI has thrown an exception
            fclose(Input_File); exit(0);
        }
```

```
        if ((cr == '@') && (col == 1)) {
            ⟨Read the rest of line as an at-heading 10⟩;
            ⟨Act on the at-heading, going in or out of comment mode as appropriate 11⟩;
            continue;
        }
        if (comment == FALSE) {
            if (default_command[0] != 0) {
                if ((cr == 10) || (cr == 13)) continue;                    skip blank lines here
                ⟨Set the command to the default, and read rest of line as argument 12⟩;
                if ((argument[0] == '!') || (argument[0] == 0)) continue;    skip blanks and comments
                if (strcmp(argument, "{-endlines}") == 0) default_command[0] = 0;
                else ⟨Act on I6T command and argument 16⟩;
                continue;
            }
            if (cr == '{') {
                ⟨Read next character from I6T stream 9⟩;
                if (cr == '-') {
                    ⟨Read up to the next close brace as an I6T command and argument 13⟩;
                    if (command[0] == '!') continue;
                    ⟨Act on I6T command and argument 16⟩;
                    continue;
                } else if ((cr == 'N') && (N_escape >= 0)) {
                    ⟨Read next character from I6T stream 9⟩;
                    if (cr == '}') {
                        WRITE("%d", N_escape);
                        continue;
                    }
                    if ((OUT) && (active)) WRITE("{N");
                    goto NewCharacter;
                } else {                                    otherwise the open brace was a literal
                    if ((OUT) && (active)) STREAM_PUT(OUT, '{');
                    goto NewCharacter;
                }
            }
            if (cr == '(') {
                ⟨Read next character from I6T stream 9⟩;
                if (cr == '+') {
                    ⟨Read up to the next plus close-bracket as an I7 expression 14⟩;
                    ⟨Evaluate the I7 expression resulting 15⟩;
                    continue;
                } else {                                  otherwise the open bracket was a literal
                    if ((OUT) && (active)) STREAM_PUT(OUT, '(');
                    goto NewCharacter;
                }
            }
            if ((OUT) && (active)) STREAM_PUT(OUT, cr);
        }
    } while (cr != EOF);
    if (Input_File) { if (dl) STREAM_FLUSH(dl); fclose(Input_File); }
    OmitFile:
    if (segment_name) I6T_file_intervene(OUT, 1, segment_name, NULL);
}
```

The function interpret_I6T_file is called from 10/isin and 14/main.

§**6.** We look for the `.i6t` files first in the `I6T` subfolder of the `Materials` folder for the project, then failing that (as we almost always will) in the `Reserved` part of the built-in extensions area. Note the way we handle a failure to open the file: if this should happen to `Main.i6t` then we must assume that the problems machinery is not in working order, because the commands to initialise this are themselves in `Main.i6t`. If it happens to any other segment then, conversely, `Main.i6t` must have opened safely and processed numerous early commands, so we can safely issue Problems.

⟨Open the I6 template file 6⟩ ≡

```
⟨Look for the I6T file in the Materials folder 7⟩;
if (Input_File == NULL) {
    ⟨Look for the I6T file in the Reserved built-in extensions area 8⟩;
    if (Input_File == NULL) {
        if (strcmp(segment_name, "Main.i6t") == 0)
            fatal_error2("Error: can't open input file", segment_name);
        STREAM_WRITE(STDERR, "inform: Unable to open segment <%s>\n", segment_name);
        unlocated_problem(_P_(BelievedImpossible),                    or anyway not usefully testable
            "I couldn't open a requested I6T segment: see the console "
            "output for details.");
    }
}
```

This code is used in §5.

§**7.** The following is a little wasteful in that it will be tried 20 or so times in a typical NI run, almost always in vain. On a platform where attempts to `fopen` nonexistent directories are slow, we might care about that.

⟨Look for the I6T file in the Materials folder 7⟩ ≡

```
int i;
char the_filename[MAX_FILENAME_LENGTH];
if (bundle_name) strcpy(the_filename, bundle_name);
else the_filename[0] = 0;
i = strlen(the_filename)-1;
while ((i>0) && (the_filename[i] != '.')) i--;
if (i>0) the_filename[i++] = ' ';
sprintf(the_filename+i, "Materials%cI6T%c%s",
    FOLDER_SEPARATOR, FOLDER_SEPARATOR, segment_name);
Input_File = iso_fopen(the_filename, "r");
```

This code is used in §6.

§**8.** Similarly, but more simply:

⟨Look for the I6T file in the Reserved built-in extensions area 8⟩ ≡

```
char the_filename[MAX_FILENAME_LENGTH];
sprintf(the_filename, "%s%cReserved%c%s",
    pathname_of_built_in_extensions,
    FOLDER_SEPARATOR, FOLDER_SEPARATOR, segment_name);
Input_File = iso_fopen(the_filename, "r");
```

This code is used in §6.

§**9.** I6 template files are encoded as ISO Latin-1, not as Unicode UTF-8, so ordinary `fgetc` is used, and no BOM marker is parsed. Lines are assumed to be terminated with either `0x0a` or `0x0d`. (Since blank lines are harmless, we take no trouble over `0a0d` or `0d0a` combinations.) The built-in template files, almost always the only ones used, are line terminated `0x0a` in Unix fashion.

⟨Read next character from I6T stream 9⟩ ≡

```
if (Input_File) cr = fgetc(Input_File);
else if (sf) {
    cr = sf[sfp]; if (cr == 0) cr = EOF; else sfp++;
} else cr = EOF;
col++; if ((cr == 10) || (cr == 13)) col = 0;
```

This code is used in §5,10,12,13,14,5,10,12,13,14,5.

§**10.** Anything following an at-character in the first column is a heading:

⟨Read the rest of line as an at-heading 10⟩ ≡

```
int i = 0;
while (i<MAX_I6T_LINE_LENGTH) {
    ⟨Read next character from I6T stream 9⟩;
    if ((cr == 10) || (cr == 13)) break;
    I6T_buffer[i++] = (char) cr;
}
I6T_buffer[i] = 0;
command = I6T_buffer;
```

This code is used in §5.

§**11.** As can be seen, only a small minority of Inweb syntaxes are allowed: in particular, no `@d` or angle-bracketed macros. This interpreter is not a full-fledged tangler.

⟨Act on the at-heading, going in or out of comment mode as appropriate 11⟩ ≡

```
if ((command[0] == 'p') && (command[1] == ' ')) {
    int i;
    if ((heading_name[0] != 0) && (segment_name))
        I6T_file_intervene(OUT, 1, segment_name, heading_name);
    strcpy(heading_name, command+2);
    i = strlen(heading_name)-1;
    while ((i>=0) &&
        ((heading_name[i] == ' ') || (heading_name[i] == '\t') || (heading_name[i] == '.'))) i--;
    heading_name[i+1] = 0;
    if (heading_name[0] == 0)
        internal_error("Empty heading name in I6 template file");
    comment = TRUE; skip_part = FALSE;
    if (segment_name) {
        I6T_file_intervene(OUT, -1, segment_name, heading_name);
        if (I6T_file_intervene(OUT, 0, segment_name, heading_name)) skip_part = TRUE;
    }
    continue;
}
if (strcmp(command, "c") == 0) {
    if (skip_part == FALSE) comment = FALSE;
    continue;
}
if (command[0] == '-') continue;
```

```
    if (strncmp(command, "Purpose:", 8) == 0) continue;
    LOG("heading: <%s>\n", command);
    internal_error("Unknown heading format in I6 template file");
```

This code is used in §5.

§**12.** Here we are in `{-lines:...}` mode, so that the entire line of the file is to be read as an argument. Note that initial and trailing white space on the line is deleted: this makes it easier to lay out I6T template files tidily.

⟨Set the command to the default, and read rest of line as argument 12⟩ ≡

```
    int i;
    strcpy(I6T_buffer, default_command);
    command = I6T_buffer;
    i = strlen(command)+1;
    argument = command + i;
    I6T_buffer[i++] = (char) cr;
    while (i<MAX_I6T_LINE_LENGTH) {
        ⟨Read next character from I6T stream 9⟩;
        if ((cr == 10) || (cr == 13)) break;
        I6T_buffer[i++] = (char) cr;
    }
    I6T_buffer[i] = 0;
    while ((argument[0] == ' ') || (argument[0] == '\t')) argument++;
    while ((I6T_buffer[i-1] == ' ') || (I6T_buffer[i-1] == '\t'))
        I6T_buffer[--i] = 0;
```

This code is used in §5.

§**13.** And here we read a normal command. The command name must not include `}` or `:`. If there is no `:` then the argument is left unset (so that it will be the empty string: see above). The argument must not include `}`.

⟨Read up to the next close brace as an I6T command and argument 13⟩ ≡

```
    int i=0;
    while (i<MAX_I6T_LINE_LENGTH) {
        ⟨Read next character from I6T stream 9⟩;
        if ((cr == '}') || (cr == EOF)) break;
        I6T_buffer[i++] = (char) cr;
    }
    I6T_buffer[i] = 0;
    command = I6T_buffer;
    for (i=0; I6T_buffer[i]; i++)
        if (I6T_buffer[i] == ':') {
            I6T_buffer[i] = 0;
            argument = I6T_buffer+i+1;
        }
```

This code is used in §5.

§**14.** And similarly, for the `(+ ... +)` notation used to mark I7 material within I6:

⟨Read up to the next plus close-bracket as an I7 expression 14⟩ ≡

```
int i=0;
while (i<MAX_I6T_LINE_LENGTH) {
    ⟨Read next character from I6T stream 9⟩;
    if (cr == EOF) { I6T_buffer[i] = 0; break; }
    if ((cr == ')') && (i>0) && (I6T_buffer[i-1] == '+')) { I6T_buffer[i-1] = 0; break; }
    I6T_buffer[i++] = (char) cr;
}
```

This code is used in §5.

§**15.** We delegate:

⟨Evaluate the I7 expression resulting 15⟩ ≡

```
TEMPORARY_STREAM;
compile_I7_expression_from_I6(TEMP, I6T_buffer);
STREAM_COPY(OUT, TEMP);
CLOSE_TEMPORARY_STREAM;
```

This code is used in §5.

§**16. Acting on I6T commands.** Only a few commands work even in passive mode, but they include file-handling because the close-file command needs to be able to get out of passive mode and back into active (and besides, because the file still needs to be closed).

The `{-type:...}` command hands over the argument to a more specific interpreter, one which constructs data types and is to be found in Chapter 7.

The `{-segment:...}` command recursively calls the I6T interpreter on the supplied I6T filename, which means it acts rather like `#include` in C. Note that because we pass the current output file handle `of` through to this new invocation, it will have the file open if we do, and closed if we do. It will run in active mode, but that's fine, because we're in active mode too. It won't run in indexing mode, so `{-segment:...}` can't be used safely between `{-open-index}` and `{-close-index}`.

⟨Act on I6T command and argument 16⟩ ≡

```
⟨Act on an I6T file-handling command 17⟩;
⟨Act on the I6T lines command 18⟩;
if (active == FALSE) continue;
if (strcmp(command, "segment") == 0) { interpret_I6T_file(OUT, NULL, argument, -1); continue; }
if (strcmp(command, "type") == 0) { despatch_type_command(argument); continue; }
⟨Act on an I6T indexing command 19⟩;
⟨Act on an I6T command which keeps track of progress 20⟩;
⟨Act on the I6T counter command 21⟩;
⟨Act on the I6T value command 22⟩;
⟨Act on the I6T read-assertions command 23⟩;
⟨Act on the I6T callv command 24⟩;
⟨Act on the I6T call command 25⟩;
⟨Act on the I6T array command 26⟩;
⟨Act on the I6T routine command 27⟩;
⟨Act on the I6T test command 28⟩;
LOG("command: <%s> argument: <%s>\n", command, argument);
internal_error("Unknown I6T command in I6 template file");
```

This code is used in §5.

§**17.** This where the primary output from NI, the I6 file it compiles, is opened.

Note that closing this file again sends us back into active move: that is so that, whatever may have happened earlier, we can still follow I6T commands to deallocate memory, issue a Problems report, and so on, as part of the finishing-up process.

⟨Act on an I6T file-handling command 17⟩ ≡

```
if (strcmp(command, "open-file") == 0) {
    if (OUT) internal_error("output file already open");
    if (STREAM_OPEN_TO_FILE(inform6_file, build_filename(I6_OUTPUT_LEAFNAME), ISO_ENC) == FALSE)
        fatal_error("Can't open output file");
    OUT = inform6_file;
    continue;
}
if (strcmp(command, "close-file") == 0) {
    if (OUT) STREAM_CLOSE(OUT);
    OUT = NULL;
    active = TRUE;
    continue;
}
```

This code is used in §16.

§**18.** There is no corresponding code here to act on `{-endlines}` because it is not valid as a free-standing command: it can only occur at the end of a `{-lines:...}` block, and is acted upon above.

⟨Act on the I6T lines command 18⟩ ≡

```
if (strcmp(command, "lines") == 0) {
    truncated_strcpy(default_command, argument, MAX_I6T_COMMAND_LENGTH);
    continue;
}
```

This code is used in §16.

§**19. Indexing commands.** Commands in between `{-open-index}` and `{-close-index}` are skipped when NI has been called with a command-line switch to disable the index. (As is done by `intest`, to save time.) `{-index:name}` opens the index file called `name`.

⟨Act on an I6T indexing command 19⟩ ≡

```
if (strcmp(command, "open-index") == 0) { indexing = TRUE; continue; }
if (strcmp(command, "close-index") == 0) { indexing = FALSE; continue; }
if ((indexing) && (do_not_generate_index)) continue;
if (strcmp(command, "index") == 0) {
    int i;
    char leafname[MAX_FILENAME_LENGTH];
    strcpy(leafname, argument);
    for (i=0; leafname[i]; i++)
        if ((leafname[i] == ' ') || (leafname[i] == '=')) {
            leafname[i] = 0;
            break;
        }
    strcpy(leafname+i, ".png");
    char titling[MAX_FILENAME_LENGTH], explanation[MAX_FILENAME_LENGTH],
        image[MAX_FILENAME_LENGTH], caption[MAX_FILENAME_LENGTH];
    strcpy(image, leafname);
```

```
        strcpy(leafname+i, ".html");
        strcpy(titling, argument); explanation[0] = 0; caption[0] = 0;
        for (i=0; titling[i]; i++)
            if (titling[i] == '=') {
                titling[i] = 0;
                if (explanation[0] == 0) strcpy(explanation, titling+i+1);
                else strcpy(caption, titling+i+1);
            }
        for (i=0; explanation[i]; i++)
            if (explanation[i] == '=') {
                explanation[i] = 0;
            }
        set_thumbnail_image(image, caption);
        open_index_file(leafname, titling, -1, explanation);
        continue;
    }
```

This code is used in §16.

§**20. Annotating progress.** The debugging log has headings at two levels: grand Phases, and mere Stages. These headings are inserted by the `{-log-phase:...}` and `{-log:...}` commands respectively. The `{-progress-stage:...}` command tells NI to print an estimate of the percentage of completion to `stdout`; the Inform interfaces usually catch this output and update graphical progress bars accordingly.

⟨Act on an I6T command which keeps track of progress 20⟩ ≡

```
    if (strcmp(command, "log") == 0) {
        log_new_stage_of_NIs_run(argument); continue;
    }
    if (strcmp(command, "log-phase") == 0) {
        char *phase_names[] = {
            "I", "II", "III", "IV", "V", "VI", "VII", "VIII", "IX", "X",
            "XI", "XII", "XIII", "XIV", "XV", "XVI", "XVII", "XVIII", "XIX", "XX" };
        log_new_phase_of_NIs_run(phase_names[no_phases], argument);
        if (no_phases < 19) no_phases++;
        continue;
    }
    if (strcmp(command, "progress-stage") == 0) {
        progress_bar(atoi(argument), 0); continue;
    }
```

This code is used in §16.

§**21. Commands accessing NI internals.** These are the real point of the I6T interpreter. We begin with two commands which take numerical values from inside NI and output them as literal decimal numbers: first, the number of labels produced for a given label namespace.

⟨Act on the I6T counter command 21⟩ ≡

```
    if (strcmp(command, "counter") == 0) {
        if (OUT == NULL) continue;
        WRITE("%d", lns_read_counter(argument, FALSE)); continue;
    }
```

This code is used in §16.

§**22.** More generally, `{-value:...}` behaves as if it evaluates ... as a C expression in NI, but of course only works for a very select few identifiers: those "allowed" by the following macro.

```
define ALLOW_VALUE(val)
    if (strcmp(argument, #val)==0) { WRITE("%d", val); continue; }
```

⟨Act on the I6T value command 22⟩ ≡

```
    if (strcmp(command, "value") == 0) {
        if (OUT == NULL) continue;
        ALLOW_VALUE(NUMBER_CREATED(action_name));
        ALLOW_VALUE(NUMBER_CREATED(binary_predicate));
        ALLOW_VALUE(NUMBER_CREATED(blorb_figure));
        ALLOW_VALUE(NUMBER_CREATED(blorb_sound));
        ALLOW_VALUE(NUMBER_CREATED(property_name));
        ALLOW_VALUE(NUMBER_CREATED(rulebook));
        ALLOW_VALUE(NUMBER_CREATED(scene));
        ALLOW_VALUE(NUMBER_CREATED(test_scenario));
        ALLOW_VALUE(NUMBER_CREATED(world_object));
        ALLOW_VALUE(OBJECT_TY);
        ALLOW_VALUE(SNIPPET_TY);
        ALLOW_VALUE(UNDERSTANDING_TY);
        ALLOW_VALUE(extent_of_runtime_quotations_array);
        ALLOW_VALUE(instance_count_for_kind(kind_door));
        ALLOW_VALUE(instance_count_for_kind(kind_room));
        ALLOW_VALUE(max_frame_size_needed);
        ALLOW_VALUE(no_verb_verb_defined);
        ALLOW_VALUE(rng_seed_at_start_of_play);
        LOG("command: <%s> argument: <%s>\n", command, argument);
        internal_error("Unknown {-value:...} value in I6 segment");
    }
```

This code is used in §16.

§**23.** Now three commands which cause the template interpreter to stop and call routines in the rest of NI, which may do something dramatic.

The first command makes `{-read-assertions:1}` and `{-read-assertions:2}` run main traverses 1 and 2 of the parse tree, in which assertion sentences are converted to inferences, among much other useful activity. Should any problem messages be issued, we go into passive mode, thus calling no further NI routines for the time being. This enables all subsequent routines to be written on the assumption that they have correct input as far as can be judged so far, which greatly simplifies error recovery.

⟨Act on the I6T read-assertions command 23⟩ ≡

```
    if (strcmp(command, "read-assertions") == 0) {
        if (strcmp(argument, "1") == 0) traverse_for_assertions(1);
        if (strcmp(argument, "2") == 0) traverse_for_assertions(2);
        if (problem_count > 0) active = FALSE;
        continue;
    }
```

This code is used in §16.

§**24.** The `{-callv:whatever}` command makes a void function call `whatever()`, and is once again allowed only for select NI functions.

Problem messages only throw us into passive mode here if the main output file has not yet been closed. This is done because we might be in the post-compilation phase where release instructions are being written, say, and a problem is found with the release requests made by the user: we mustn't go into passive mode in such a case, because then we wouldn't be able to deallocate memory, complete the problems report with these problem messages in, and so on.

```
define ALLOW_CALLV(routine)
    if (strcmp(argument, #routine)==0) {
        routine();
        if ((problem_count > 0) && (closed == FALSE)) active = FALSE;
        continue;
    }
```

⟨Act on the I6T callv command 24⟩ ≡

```
    if (strcmp(command, "callv") == 0) {
        ALLOW_CALLV(add_rules_to_rulebooks);
        ALLOW_CALLV(allow_no_further_deferrals);

        ALLOW_CALLV(verify_parse_tree);
        ALLOW_CALLV(write_headings_as_xml);
        ALLOW_CALLV(write_ifiction_and_blurb);
        LOG("command: <%s> argument: <%s>\n", command, argument);
        internal_error("Unknown {-callv:...} function in I6 segment");
    }
```

This code is used in §16.

§**25.** And the `{-call:whatever}` command makes a function call `whatever(OUT)`, supplying the output file handle as an argument, and is once again allowed only for select NI functions.

```
define ALLOW_CALL(routine)
    if (strcmp(argument, #routine)==0) { routine(OUT); continue; }
```

⟨Act on the I6T call command 25⟩ ≡

```
    if (strcmp(command, "call") == 0) {
        if (OUT == NULL) continue;
        ALLOW_CALL(add_showme_details);
        ALLOW_CALL(chronology_extents_i6_escape);

        ALLOW_CALL(past_tenses_i6_escape);
        ALLOW_CALL(resolve_predeclared_booked_rules);
        ALLOW_CALL(write_test_text);
        LOG("command: <%s> argument: <%s>\n", command, argument);
        internal_error("Unknown {-call:...} function in I6 segment");
    }
```

This code is used in §16.

§**26.** The `{-array:...}` command tells NI to compile an I6 array with the given name which must, of course, be one of those in its repertoire.

define `ALLOW_ARRAY(array)`

```
    if (strcmp(argument, #array)==0) { compile_##array##_array(OUT); continue; }
```

⟨Act on the I6T array command 26⟩ ≡

```
    if (strcmp(command, "array") == 0) {
        if (OUT == NULL) continue;
        ALLOW_ARRAY(ActionCoding);
        ALLOW_ARRAY(ActionData);
        ALLOW_ARRAY(ActionHappened);
        ALLOW_ARRAY(Activity_after_rulebooks);
        ALLOW_ARRAY(Activity_atb_rulebooks);
        ALLOW_ARRAY(Activity_before_rulebooks);
        ALLOW_ARRAY(activity_var_creators);
        ALLOW_ARRAY(Activity_for_rulebooks);
        ALLOW_ARRAY(ConstantListPointers);
        ALLOW_ARRAY(Global_Vars);
        ALLOW_ARRAY(TimedEventsTable);
        ALLOW_ARRAY(TimedEventTimesTable);
        ALLOW_ARRAY(InitialSituation);
        ALLOW_ARRAY(property_metadata);
        ALLOW_ARRAY(relation_metadata);
        ALLOW_ARRAY(rulebook_var_creators);
        ALLOW_ARRAY(RulebookNames);
        ALLOW_ARRAY(rulebooks_array);
        ALLOW_ARRAY(scene_recurs);
        ALLOW_ARRAY(tableoffigures);
        ALLOW_ARRAY(tableofsounds);
        ALLOW_ARRAY(UUID_ARRAY);
        LOG("command: <%s> argument: <%s>\n", command, argument);
        internal_error("Unknown {-array:...} function in I6 segment");
    }
```

This code is used in §16.

§**27.** And the `{-routine:...}` command tells NI to compile an I6 routine with the given name. (There are very few of these, because we try to let template files choose the names of routines, for the most part.)

```
define ALLOW_ROUTINE(routine)
    if (strcmp(argument, #routine)==0) { compile_##routine##_routine(OUT); continue; }
```

⟨Act on the I6T routine command 27⟩ ≡

```
    if (strcmp(command, "routine") == 0) {
        if (OUT == NULL) continue;
        ALLOW_ROUTINE(CreatePropertyOffsets);
        ALLOW_ROUTINE(I7_Kind_Name);
        ALLOW_ROUTINE(RulebookOutcomePrintingRule);
        ALLOW_ROUTINE(DetectSceneChange);
        ALLOW_ROUTINE(ShowSceneStatus);
        ALLOW_ROUTINE(PrintSceneName);
        ALLOW_ROUTINE(ShowExtensionVersions);
        ALLOW_ROUTINE(TestUseOption);
        ALLOW_ROUTINE(MistakeActionSub);
        ALLOW_ROUTINE(InternalTestCases);
        LOG("command: <%s> argument: <%s>\n", command, argument);
        internal_error("Unknown {-array:...} function in I6 segment");
    }
```

This code is used in §16.

§**28.** And the `{-test:...}` command tells NI that an I6 verb directive follows for a testing verb. We want to know that in order to police accidental clashes between testing commands built in the template, and genuine commands defined in the source text.

⟨Act on the I6T test command 28⟩ ≡

```
    if (strcmp(command, "testing-command") == 0) {
        if (OUT == NULL) continue;
        reserve_command_verb(argument);
        WRITE("Verb meta '%s'\n", argument);
        continue;
    }
```

This code is used in §16.

§**29. I7 expression evaluation.** This is not quite like regular expression evaluation, because we want "room" and "lighted" to be evaluated as the I6 translation of the relevant class or property, rather than as code to test the predicate "X is a room" or "X is lighted", and similarly for bare names of defined adjectives. So:

```
void compile_I7_expression_from_I6(OUTPUT_STREAM, char *p) {
    feed_into_lexer(p, FALSE, FALSE);
    property_name *prn = parse_property_name(lexer_feed_w1, lexer_feed_w2);
    if (prn) {
        WRITE("%s", prn_get_i6_identifier(prn));
        return;
    }
    world_object *wo = parse_world_object(lexer_feed_w1, lexer_feed_w2, FALSE);
    if (wo) {
        WRITE("%s", wo_get_I6_representation(wo));
        return;
```

```
    }
    int initial_problem_count = problem_count;
    specification *spec = parse_expression(lexer_feed_w1, lexer_feed_w2, VALUE_EXPCON);
    if (initial_problem_count < problem_count) return;
    typecheck_without_expectations(spec);
    if (initial_problem_count < problem_count) return;
    spec_compile(OUT, spec);
}
```

§**30. Intervention.** This is a system allowing the user to hang explicit code before, instead of or after any part of any segment of the I6T files in use.

```
void I6T_intervention_new(int stage, char *segment, char *part, char *i6, char *seg) {
    I6T_intervention *i6ti = NULL;
    if (stage == 0) {
        LOOP_OVER(i6ti, I6T_intervention)
            if ((i6ti->intervention_stage == 0) &&
                (strcmp(i6ti->segment_name, segment) == 0)) {
                if (((part == NULL) || (i6ti->part_name == NULL)) && (part != i6ti->part_name))
                    continue;
                if ((part) && (strcmp(i6ti->part_name, part) != 0)) continue;
                break;
            }
    }
    if (i6ti == NULL) i6ti = CREATE(I6T_intervention);
    i6ti->intervention_stage = stage;
    i6ti->segment_name = segment;
    i6ti->part_name = part;
    i6ti->I6T_matter = i6;
    i6ti->alternative_segment = seg;
    i6ti->segment_found = FALSE;
    i6ti->part_found = FALSE;
    i6ti->where_intervention_requested = current_sentence;
    LOGIF(SEGMENTS, "New stage %d Segment %s Part %s\n", stage, segment, (part)?part:"<none>");
}
```

The function I6T_intervention_new is called from 10/isin.

§**31.** An intervention "instead" (stage 0) replaces any existing one, but at other stages – before and after – they are accumulated.

```
int I6T_file_intervene(OUTPUT_STREAM, int stage, char *segment, char *part) {
    I6T_intervention *i6ti;
    int rv = FALSE;
    if (strcmp(segment, "Main.i6t") == 0) return rv;
    LOGIF(SEGMENTS, "Stage %d Segment %s Part %s\n", stage, segment, (part)?part:"<none>");
    LOOP_OVER(i6ti, I6T_intervention)
        if ((i6ti->intervention_stage == stage) &&
            (strcmp(i6ti->segment_name, segment) == 0)) {
            i6ti->segment_found = TRUE;
            if (((part == NULL) || (i6ti->part_name == NULL)) && (part != i6ti->part_name))
                continue;
            if ((part) && (strcmp(i6ti->part_name, part) != 0)) continue;
            i6ti->part_found = TRUE;
            LOGIF(SEGMENTS, "Intervention at stage %d Segment %s Part %s\n", stage, segment, (part)?part:"<none>")
            if (i6ti->I6T_matter) interpret_I6T_file(OUT, i6ti->I6T_matter, NULL, -1);
            if (i6ti->alternative_segment) interpret_I6T_file(OUT, NULL, i6ti->alternative_segment,
-1);
            if (stage == 0) rv = TRUE;
        }
    return rv;
}
```

§**32.** At the end of the run, we check to see if any of the interventions were never acted on. This generally means the user mistyped the name of a section or part – which would otherwise be an error very difficult to detect.

```
void report_unacted_upon_interventions(void) {
    I6T_intervention *i6ti;
    LOOP_OVER(i6ti, I6T_intervention) {
        if ((i6ti->segment_found == FALSE) && (strcmp(i6ti->segment_name, "Main.i6t") != 0)) {
            current_sentence = i6ti->where_intervention_requested;
            sentence_problem(_P_(C14NoSuchTemplate),
                "no template file of that name was ever read in",
                "so this attempt to intervene had no effect. "
                "The template files have names like 'Output.i6t', 'Parser.i6t' "
                "and so on. (Looking at the typeset form of the template, "
                "available at the Inform website, may help.)");
        } else if ((i6ti->part_found == FALSE) && (i6ti->part_name) &&
            (strcmp(i6ti->segment_name, "Main.i6t") != 0)) {
            current_sentence = i6ti->where_intervention_requested;
            sentence_problem(_P_(C14NoSuchPart),
                "that template file didn't have a part with that name",
                "so this attempt to intervene had no effect. "
                "Each template file is divided internally into a number of "
                "named parts, and you have to quote their names precisely. "
                "(Looking at the typeset form of the template, available at "
                "the Inform website, may help.)");
        }
    }
}
```

The function report_unacted_upon_interventions is invoked by a command in a `.i6t` template file.

§33. The build constant. That was the end of the template interpreter. Now, since this version-numbering constant belongs nowhere else, we provide a single I6T command in this section of NI: the following routine performs `{-call:compile_build_number}`.

```
void compile_build_number(OUTPUT_STREAM) {
    WRITE("Constant NI_BUILD_COUNT \"%s\";\n", NI_BUILD);
}
```

The function compile_build_number is invoked by a command in a `.i6t` template file.

§34. Registration of sentence handlers. The following routine is placed here, right at the end of the NI code, because at this point all of the sentence handlers – with names like `TABLE_SH_handler` – have now been created.

```
void register_sentence_handlers(void) {
    ⟨Add sentence handlers for the top-level node types 35⟩;
    ⟨Add sentence handlers for the SENTENCE/VERB node types 36⟩;
}
```

The function register_sentence_handlers is called from 8/tass.

§35. This is all of the node types still present at the top level of the tree at the end of sentence-breaking.

⟨Add sentence handlers for the top-level node types 35⟩ ≡

```
    REGISTER_SENTENCE_HANDLER(TRACE_SH);
    REGISTER_SENTENCE_HANDLER(BEGINHERE_SH);
    REGISTER_SENTENCE_HANDLER(ENDHERE_SH);
    REGISTER_SENTENCE_HANDLER(BIBLIOGRAPHIC_SH);
    REGISTER_SENTENCE_HANDLER(INFORM6CODE_SH);
    REGISTER_SENTENCE_HANDLER(COMMAND_SH);
    REGISTER_SENTENCE_HANDLER(ROUTINE_SH);
    REGISTER_SENTENCE_HANDLER(TABLE_SH);
    REGISTER_SENTENCE_HANDLER(EQUATION_SH);
    REGISTER_SENTENCE_HANDLER(HEADING_SH);
    REGISTER_SENTENCE_HANDLER(SENTENCE_SH);
```

This code is used in §34.

§**36.** And here are all of the verb types found in `VERB_NT` nodes which are first children of `SENTENCE_NT` nodes.

⟨Add sentence handlers for the SENTENCE/VERB node types 36⟩ ≡

```
REGISTER_SENTENCE_HANDLER(ASSERT_SH);
REGISTER_SENTENCE_HANDLER(HAS_SH);
REGISTER_SENTENCE_HANDLER(CANBE_SH);
REGISTER_SENTENCE_HANDLER(TRANSLATES_SH);
REGISTER_SENTENCE_HANDLER(TRANSLATESU_SH);
REGISTER_SENTENCE_HANDLER(NEW_ACTIVITY_SH);
REGISTER_SENTENCE_HANDLER(NEW_ACTION_SH);
REGISTER_SENTENCE_HANDLER(NEW_RELATION_SH);
REGISTER_SENTENCE_HANDLER(DOC_SH);
REGISTER_SENTENCE_HANDLER(TEST_SH);
REGISTER_SENTENCE_HANDLER(USEMEANS_SH);
REGISTER_SENTENCE_HANDLER(SPECIFIES_SH);
REGISTER_SENTENCE_HANDLER(DEFINED_BY_SH);
REGISTER_SENTENCE_HANDLER(BEGINS_WHEN_SH);
REGISTER_SENTENCE_HANDLER(ENDS_WHEN_SH);
REGISTER_SENTENCE_HANDLER(USE_SH);
REGISTER_SENTENCE_HANDLER(RELEASE_SH);
REGISTER_SENTENCE_HANDLER(EPISODE_SH);
REGISTER_SENTENCE_HANDLER(PLURAL_SH);
REGISTER_SENTENCE_HANDLER(FIGURE_SH);
REGISTER_SENTENCE_HANDLER(SOUND_SH);
REGISTER_SENTENCE_HANDLER(FILE_SH);
```

This code is used in §34.

A The Standard Rules

`A/sr0`: *SR0 - Preamble.w* The titling line and rubric, use options and a few other technicalities before the Standard Rules get properly started.

`A/sr1`: *SR1 - Physical World Model.w* Verbal descriptions of spatial relationships; the hierarchy of kinds of object, and their properties.

`A/sr2`: *SR2 - Variables and Rulebooks.w* The global variables and those built-in rulebooks which do not belong either to specific actions or to specific activities.

`A/sr3`: *SR3 - Activities.w* The built-in activities and their default stock of rules; the locale description mechanism.

`A/sr4`: *SR4 - Actions.w* The standard stock of actions supplied with Inform, along with the rules which define them; and the Understand grammar which corresponds to them.

`A/sr5`: *SR5 - Phrase Definitions.w* The phrases making up the Inform language, and in terms of which all other phrases and rules are defined; and the final sign-off of the Standard Rules extension, including its minimal documentation.

SR0 - Preamble A/sr0

Purpose

The titling line and rubric, use options and a few other technicalities before the Standard Rules get properly started.

A/sr0.§2 Title; §3-7 Starting up

---

§**1.** The Standard Rules are like a boot program for a computer that is starting up: at the beginning, the process is delicate, and the computer needs a fairly exact sequence of things to be done; halfway through, the essential work is done, but the system is still too primitive to be much use, so we begin to create convenient intermediate-level code sitting on top of the basics; so that, by the end, we have a fully flexible machine ready to go in any number of directions. In this commentary, we try to distinguish between what must be done (or else NI will crash, or fail in some other way) and what is done simply as a design decision (to make the Inform language come out the way we want it). Quite interesting hybrid Informs could be built by making different decisions. Still, our design is not entirely free, since it interacts with the I6 template layer (the I7 equivalent of the old I6 library): a really radical alternate Inform would need a different template layer, too.

§**2. Title.** Every Inform 7 extension begins with a standard titling line and a rubric text, and the Standard Rules are no exception:

```
Version 2/090402 of the Standard Rules by Graham Nelson begins here.
"The Standard Rules, included in every project, define the basic framework
of kinds, actions and phrases which make Inform what it is."
```

§**3. Starting up.** The following block of declarations is actually written by `indoc` and modified each time we alter the documentation. It's a dictionary of symbolic names like `HEADINGS` to HTML page leafnames like `doc71`.

...and so on...

§**4.** Some Inform 7 projects are rather heavy-duty by the expectations of the Inform 6 compiler (which it uses as a code-generator): I6 was written fifteen years earlier, when computers were unimaginably smaller and slower. So many of its default memory settings need to be raised to higher maxima.

Note that the Z-machine cannot accommodate more than 255 verbs, so this is the highest `MAX_VERBS` setting we can safely make here.

```
Use MAX_ARRAYS of 1500.
Use MAX_CLASSES of 200.
Use MAX_VERBS of 255.
Use MAX_LABELS of 10000.
Use MAX_ZCODE_SIZE of 50000.
Use MAX_STATIC_DATA of 120000.
Use MAX_PROP_TABLE_SIZE of 200000.
Use MAX_INDIV_PROP_TABLE_SIZE of 20000.
Use MAX_STACK_SIZE of 65536.
Use MAX_SYMBOLS of 20000.
Use MAX_EXPRESSION_NODES of 256.
```

§**5.** These, on the other hand, are settings used by the dynamic memory management code, which runs in I6 as part of the template layer. Each setting translates to an I6 constant declaration, with the value chosen being substituted for `{N}`.

The "dynamic memory allocation" defined here is slightly misleading, in that the memory is only actually consumed in the event that any of the data types needing to use the heap are actually employed in the source text being compiled. (8192 bytes may not sound much these days, but in the tight array space of the Z-machine it's quite a large commitment, and we want to avoid it whenever possible.)

```
Use dynamic memory allocation of at least 8192 translates as
    (- Constant DynamicMemoryAllocation = {N}; -).
Use maximum indexed text length of at least 1024 translates as
    (- Constant IT_MemoryBufferSize = {N}+3; -).

Use dynamic memory allocation of at least 8192.
```

§**6.** This setting is to do with the Inform parser's handling of multiple objects.

```
Use maximum things understood at once of at least 100 translates as
    (- Constant MATCH_LIST_WORDS = {N}; -).

Use maximum things understood at once of at least 100.
```

§**7.** Finally, some definitions of miscellaneous options: none are used by default, but all translate into I6 constant definitions if used. (These are constants whose values are used in the I6 library or in the template layer, which is how they have effect.)

```
Use American dialect translates as (- Constant DIALECT_US; -).
Use the serial comma translates as (- Constant SERIAL_COMMA; -).
Use full-length room descriptions translates as (- Constant I7_LOOKMODE = 2; -).
Use abbreviated room descriptions translates as (- Constant I7_LOOKMODE = 3; -).
Use memory economy translates as (- Constant MEMORY_ECONOMY; -).
Use authorial modesty translates as (- Constant AUTHORIAL_MODESTY; -).
Use no scoring translates as (- Constant NO_SCORING; -).
Use command line echoing translates as (- Constant ECHO_COMMANDS; -).
Use undo prevention translates as (- Constant PREVENT_UNDO; -).
Use predictable randomisation translates as (- Constant FIX_RNG; -).
Use fast route-finding translates as (- Constant FAST_ROUTE_FINDING; -).
Use slow route-finding translates as (- Constant SLOW_ROUTE_FINDING; -).
Use numbered rules translates as (- Constant NUMBERED_RULES; -).
Use telemetry recordings translates as (- Constant TELEMETRY_ON; -).
```

SR1 - Physical World Model A/sr1

Purpose

Verbal descriptions of spatial relationships; the hierarchy of kinds of object, and their properties.

---

§**1.** Although at this point we can freely use the exceptional fixed-form command sentences – like "Use ⟨use-option⟩" – since their wording is built into NI, we are very limited in the general assertion sentences we can make. Only two verbs are built in, and this is because they require rather special handling: *to be*, since it is both fundamental and irregular; and *to have*, since although regular is it used also as an auxiliary coupled with *to be* (as in "if Daphne has been in the garden"). And no prepositions exist at all.

Well, we can't do much in talking about the world model without the fundamental spatial relationships of being inside, on top of and so forth. While the relations themselves are built-in to NI, and so are their one-word names (such as "containment"), the rest is down to us:

```
Part SR1 - The Physical World Model

Section SR1/0 - Language

The verb to provide (he provides, they provide, he provided, it is provided,
he is providing) implies the provision relation.

The verb to be in implies the reversed containment relation.
The verb to be inside implies the reversed containment relation.
The verb to be within implies the reversed containment relation.
The verb to be held in implies the reversed containment relation.
The verb to be held inside implies the reversed containment relation.

The verb to contain (he contains, they contain, he contained, it is contained,
he is containing) implies the containment relation.
The verb to be contained in implies the reversed containment relation.

The verb to be on implies the reversed support relation.
The verb to be on top of implies the reversed support relation.

The verb to support (he supports, they support, he supported, it is supported,
he is supporting) implies the support relation.
The verb to be supported on implies the reversed support relation.

The verb to incorporate (he incorporates, they incorporate, he incorporated,
it is incorporated, he is incorporating) implies the incorporation relation.
The verb to be part of implies the reversed incorporation relation.
The verb to be a part of implies the reversed incorporation relation.
The verb to be parts of implies the reversed incorporation relation.
```

§**2.** The enclosure relation, indirectly defined in terms of the above more fundamental ones, has a verb but no prepositions (though of course "to be enclosed by" is in effect a prepositional expression of this).

```
The verb to enclose (he encloses, they enclose, he enclosed, it is enclosed,
he is enclosing) implies the enclosure relation.
```

§**3.** Those three relations expressed how the inanimate world is arranged, on the small scale: the relationships become a little more complicated once living beings are involved. One living being is special to our language – the protagonist character, that is, the "player" – and so these three verbs all have adjectival forms which imply the player as the missing term. Thus, to say "The felt hat is worn." implies "...by the player": the curious syntax "(adjectival)" below, applied to the past participle, causes this to happen. This is a syntax not documented in the Inform manuals and which may change to be replaced with something more general later on; for the moment, please do not use it.

```
The verb to carry (he carries, they carry, he carried, it is carried
(adjectival), he is carrying) implies the carrying relation.
The verb to hold (he holds, they hold, he held, it is held (adjectival),
he is holding) implies the holding relation.
The verb to wear (he wears, they wear, he wore, it is worn (adjectival),
he is wearing) implies the wearing relation.
```

§**4.** Animate beings also have the ability to see and touch their surroundings, but note that we only model the ability to do these things – we do not attempt to track what they actually do see or touch at any given moment, so there are no built-in verbs *to see* or *to touch*.

```
The verb to be able to see (he is seen) implies the visibility relation.
The verb to be able to touch (he is touched) implies the touchability relation.
```

§**5.** The special status of the player as the sensory focus, so to speak, is again shown in the adjectives defined here:

```
Definition: Something is visible rather than invisible if the player can see it.
Definition: Something is touchable rather than untouchable if the player can touch it.
```

§**6.** While many of the world-modelling assumptions in I7 are carried over from those tried and tested by I6, the idea of concealment is an exception. The old I6 attribute `concealed` simply marked some objects (which we would call "things") as being hidden from view in some way, but was never very satisfactory. What does hidden mean, exactly – to whose eyes, and in what way? Should you be able to take something which is hidden, if you happen to know it's there? And so on. It was the muddiest of all the attributes, and widely disused as a result. In I7, we instead took the view that concealment required an active agent continuously doing the concealing: it applies, for instance, to a dagger which someone intentionally hides beneath a cloak, but not to a key placed at the back of a shelf by somebody long gone.

```
The verb to conceal (he conceals, they conceal, he concealed, it is concealed,
he is concealing) implies the concealment relation.
Definition: Something is concealed rather than unconcealed if the holder of it conceals it.
```

§**7.** A final sort of pseudo-containment: does the entire world contain something, or not? (For things destroyed during play, or not yet created, the answer would be no.) These definitions are rather crudely made not in terms of a defined verb *to include* but instead use the phrase "the world model includes ...", which will be defined later. (It doesn't matter that it hasn't been defined yet, because definitions, phrases and rules can be made in any order and still refer to each other.)

```
Definition: Something is on-stage rather than off-stage if I6 routine "OnStage"
    says so (it is indirectly in one of the rooms).
```

§**8. Verbal descriptions of numerical comparisons.** We might as well declare these now, too, though they're not needed for any of the world-building work. (The verbal usages `<`, `>`, `<=` and `>=` are built into NI; those would be the same in any language, and are unlike other verbs since they have no inflected forms for non-present tenses.)

```
The verb to be greater than implies the numerically-greater-than relation.
The verb to be less than implies the numerically-less-than relation.
The verb to be at least implies the numerically-greater-than-or-equal-to relation.
The verb to be at most implies the numerically-less-than-or-equal-to relation.
```

§**9. Creating the world model.** The 0th kind, "kind", is not created here but by NI itself. The first through to ninth kinds created now follow: they must not be reordered or moved. Note the two alterative plural definitions for the word "person", with "people" being defined earlier to make it the default: "persons" is correct, but "people" is more idiomatically usual.

```
Section SR1/1 - Primitive Kinds

A room is a kind. [1]
A thing is a kind. [2]
A direction is a kind. [3]
A door is a kind of thing. [4]
A container is a kind of thing. [5]
A supporter is a kind of thing. [6]
A backdrop is a kind of thing. [7]
The plural of person is people. The plural of person is persons.
A person is a kind of thing. [8]
A region is a kind. [9]
```

§**10.** At this point, then, the hierarchy looks like so:

```
kind
    room [1]
    thing [2]
        door [4]
        container [5]
        supporter [6]
        backdrop [7]
        person [8]
    direction [3]
    region [9]
```

This framework is the minimum kit needed in order for NI to be able to manage the spatial relationships arising from its basic verbs. Room and thing are needed to distinguish places and objects; door and backdrop because they need to violate the basic rule that an object can only be in one place at once – a door is "in" both of the rooms it faces onto – and this requires special handling by NI; region because it violates the rule that rooms are not themselves subject to being contained in other objects, and again this requires special handling. That leaves "direction", "container", "supporter" and "person", and these are needed to express the concepts inherent in the sentences "A is east of B", "A is in B", "A is on B" and "A is carried by B". (We also need room and person in order to make sense of the words "somewhere" and "someone", for instance.)

Although further kinds will be created later ("vehicle", for instance), those are merely design choices, and NI would not be troubled by their absence.

§**11. Rooms.** We now detail each of the fundamental kinds in turn, in order of their declaration, and thus beginning with rooms.

```
Section SR1/2 - Rooms

The specification of room is "Represents geographical locations, both indoor
and outdoor, which are not necessarily areas in a building. A player in one
room is mostly unable to sense, or interact with, anything in a different room.
Rooms are arranged in a map."
```

§**12.** Rooms have rather few properties built in; this reflects their usual role in IF as ambient environments in which interesting things happen, rather than being direct participants.

```
A room can be privately-named or publically-named. A room is usually publically-named.
A room can be lighted or dark. A room is usually lighted.
A room can be visited or unvisited. A room is usually unvisited.

A room has a text called description.
A room has a text called printed name.
```

§**13.** Note that the "map region" property here is created with the type "object", not "region", even though we think of it as always being a region. This is because of I7's type-checking rule: the type "object" can legally hold 0, meaning "nothing", but more specific object types – in this case "region" – cannot. That would make them illegal to use in a situation where no regions were created, because variables or properties of this kind couldn't be initialised. This is why the Standard Rules almost always declare object properties as "object" rather than anything more specific.

```
A room has an object called map region. The map region of a room is usually nothing.
```

§**14.** Rooms have two specialised spatial relationships of their own, which again we need verbal forms of:

```
The verb to be adjacent to implies the reversed adjacency relation.
Definition: A room is adjacent if it is adjacent to the location.

The verb to be regionally in implies the reversed regional-containment relation.
```

§**15.** There's no detailed writeup of regions, since they have no properties in the usual setup. So let's add this here for the Kinds index:

```
The specification of region is "Represents a broader area than a single
room, and allows rules to apply to a whole geographical territory. Each
region can contain many rooms, and regions can even be inside each other,
though they cannot otherwise overlap. For instance, the room Place d'Italie
might be inside the region 13th Arrondissement, which in turn is inside
the region Paris. Regions are useful mainly when the world is a large one,
and are optional."
```

§**16. Things.** Things are ubiquitous:

```
Section SR1/3 - Things

The specification of thing is "Represents anything interactive in the model
world that is not a room. People, pieces of scenery, furniture, doors and
mislaid umbrellas might all be examples, and so might more surprising things
like the sound of birdsong or a shaft of sunlight."
```

§**17.** The large number of either/or properties things can have reflects the flexibility of the I6 world model, which we largely adopt for I7 too. That is, you can have any combination of lit/unlit, edible/inedible, fixed in place/portable, and so on. We can divide them into three broad categories: first, physical properties. Things come in $2^6 = 64$ physically different varieties, which is rather a lot, but although some combinations are very rare (edible lit pushable between rooms scenery is not met with often) this flexibility is helpful in mitigating the rigidity of the kinds structure, given that we have single inheritance of kinds. Note that, except for "lit", these are all really to do whether and how people can move things around – even edibility, which is the ability to be removed from the world model entirely.

```
A thing can be lit or unlit. A thing is usually unlit.
A thing can be edible or inedible. A thing is usually inedible.
A thing can be fixed in place or portable. A thing is usually portable.
A thing can be scenery.
A thing can be wearable.
A thing can be pushable between rooms.
```

§**18.** Second, status properties, which in effect refer to the past history of an item without our needing to use the past tenses (which can be tricky or inefficient). "Handled" means that the player has at some time carried the thing in question, "initially carried" means that the player started with it. ("Carried", which means the player is carrying it now, is not defined as an either/or property but as an adjectival use of the past participle of *to carry*: see above.)

```
A thing can be handled.
A thing can be initially carried.
```

§**19.** Third, linguistic properties, influencing when and how the thing's name will be included in lists. ("Mentioned" goes here rather than as a status property because it refers only to the current room description, so it carries no long-term historic information. "Marked for listing", similarly, carries only short-term information and is used as workspace by the I6 library and also by some of the I7 template routines.)

```
A thing can be privately-named or publically-named. A thing is usually publically-named.
A thing can be plural-named or singular-named. A thing is usually singular-named.
A thing can be proper-named or improper-named. A thing is usually improper-named.
A thing can be described or undescribed. A thing is usually described.
A thing can be marked for listing or unmarked for listing. A thing is usually
unmarked for listing.
A thing can be mentioned or unmentioned. A thing is usually mentioned.
```

§**20.** We now have a mixed bag of value properties, all descriptive – it's an interesting reflection on how qualitative English text usually is that the world model so seldom needs quantitative properties (sizes, weights, distances, and so on).

```
A thing has a text called an indefinite article.
A thing has a text called a description.
A thing has a text called an initial appearance.
A thing has a text called printed name.
A thing has a text called a printed plural name.
```

§**21.** The kind "thing", like all kinds of object, is compiled by NI into an I6 `Class` definition. The three `component_*` properties form up the "part of" hierarchy: if A and B are parts of C then the `component_parent` of both A and B is C, while A is the `component_child` of C and B is the `component_sibling` of A. (This is all directly analogous to I6's built in object tree for containment and support. Incorporation, being a part of, was a concept which didn't exist in the I6 world model, and we choose not to implement in a way matching the I6 handing of containment and support because we want the extra flexibility of allowing anything to incorporate anything else – we don't want the restrictions inherent in the way, in I6, something can be either a container or a supporter but not both. This is why incorporation is not tied to any I7 kind, or any I6 class – there's no notion of "incorporator" – even though linguistically the incorporation, containment and support relations are so similar to each other. Anyway, the reason something can't be both `container` and `supporter` in I6 is ultimately because they share the same tree structure: to escape from that, we need incorporation to have a tree all its own at the I6 level, and this is it.)

```
Include (-
    with component_parent nothing, component_sibling nothing, component_child nothing,
-) when defining a thing.
```

§**22.** Lastly on things: an implication about scenery. The following sentence looks like an assertion much like others above ("A thing is usually inedible", for instance) – but this is misleading. What is different is that instead of reading $K(x) \Rightarrow Q(x)$, where K is a kind and Q is a property, this has the form $P(x) \Rightarrow Q(x)$: it says that an object having property P also probably has property Q. Such sentences are called implications, and the Standard Rules make only very sparing use of them. They can trip up the user (who may quite reasonably say that it is up to him what properties something has): but they are invaluable if they cause Inform to make deductions which any human reader would always make without thought.

They can of course be overruled by explicit sentences in the source text, just as every sentence qualified by "usually" can.

The handful of implications in the Standard Rules are all commented as such.

```
Scenery is usually fixed in place. [An implication.]
```

§**23. Directions.** The first important point about directions is that they are not things and not rooms. They are not positions in the world, but imaginary arrows pointing in different ways one could go from those positions. In the language of geometry, we could call them tangent vectors which can be taken anywhere in space by parallel transport without altering them: that's to say, the "north" in one place is the same as the "north" anywhere else. (This is how we get away with having just one set of 12 direction objects, not 12 different ones for every location.) Implicit in that assumption is that the model world occupies a "flat" Euclidean space, to use further mathematical jargon: it doesn't wrap around on itself, and there are no bad positions where the directions fail. (Compare the Infocom game *Leather Goddesses of Phobos*, in which the South Pole of Mars is just such a singularity: there are three routes out of this location, all of them "north". This of course required special programming, and so it would in an Inform 7 work, too.) More concisely:

```
Section SR1/4 - Directions

The specification of direction is "Represents a direction of movement, such
as northeast or down. They always occur in opposite, matched pairs: northeast
and southwest, for instance; down and up."
```

§**24.** The only either/or property created for directions is used to allow them to be part of lists of objects:

```
A direction can be privately-named or publically-named. A direction is usually
publically-named.
A direction can be marked for listing or unmarked for listing. A direction is
usually unmarked for listing.
```

§**25.** The following value property expresses that all directions in I7 come in matched, diametrically opposing pairs – north/south, up/down and so on. This is a concept we need to provide so that I7 can apply its assumption that if room X is north of room Y, then probably room Y is also south of room X, and so on. (Geometrically, this is the operation of negation in the tangent bundle.) Note that the kind of value here is "direction", not "object": a value of 0, meaning "there's no opposite", is illegal.

```
A direction has a direction called an opposite.
```

§**26.** I6 historically began with no formal concept of "direction" and has no `direction` attribute marking some of its objects as directions (it looked instead for object-tree chidren of a pseudo-object called `compass`); by the time I6 did want such a formal concept, the use of attributes to encode what amounted to class membership was no longer thought to be good practice. So I6 directions are now expected to belong to a class called `CompassDirection`, and here we assert just that.

Our I7 directions will be created just like any other I7 objects, but we want them to emerge with the traditional names which I6 direction objects had: so, because the I6 object for north was always called `n_obj`, we want to ensure that the I7 direction "north" also comes out as `n_obj` in the compiled code. Special translates-into-I6-as sentences are used to force the I7 object compiler to use a given I6 identifier to represent the object, rather inventing something like `O12_north` as it otherwise would.

```
Include (- class CompassDirection, -) when defining a direction.
```

§**27.** The Standard Rules define only thirteen I7 objects, and here we go with twelve of them: the standard set of directions, which come in six pairs of opposites.

The following set – N/S, NE/SW, E/W, SE/NW, U/D, IN/OUT – is rooted in IF tradition. It seems unlikely that people would make IN/OUT a pair of directions today if starting from a clean slate: this is really a residue of the traditional implementation, in 70s and 80s IF, of commands which moved the player in unorthodox way. Outside the cave mouth, typing IN should take you inside; in the Y2 Rock Room, typing the magic word PLUGH should take you far away. The most convenient way to implement such commands in as few instructions as possible was to regard these as little-used compass directions rather than independent commands (some implementations of the original Adventure regarded XYZZY, PLUGH, PLOVER as all being directions, thus using 15 of the 16 possibilities which could be represented in a 4-bit field). In the 90s this was seen to be a little bogus, but since IN and OUT clearly applied in a variety of settings, they continued to be regarded as bona fide directions. In effect, they allow for one location to surround another: the canonical example would be a small white building in the middle of a field. Anyway, I7 accepts the current orthodoxy, so IN/OUT are allowed, even though they cause headaches for the interpretation of words like "inside" which might refer either to the "horizontal" or "vertical" spatial models as a result.

Of the rest, N/S, NE/SW, E/W, SE/NW and U/D, it's noteworthy that this choice imposes a cubical grid on the world, simply because the compass directions are at 45 and 90 degree angles to each other: a hexagonal tessalation would be more faithful to distances (it would get rid of the awkward point that a NE move is $\sqrt{2}$ times the length of a N move), but in practice the world model doesn't care much about distances, another example of its qualitative nature. A further point is that, in a three-dimensional cubic lattice, we ought to have another eight pairs of directions for "up and northeast", "down and west" and so on – instead of which U/D are the only ways out of the horizontal plane. But natural language doesn't work that way: it overwhelmingly provides words for horizontal travel, because that's the plane in which our eyes normally see, and in which we normally walk. Linguistically, "north" genuinely means north, but "up" allows for any amount of lateral movement into the bargain. It's a doctrine of I7 that linguistic bias is a good guide to what's worth modelling and what is not, so we will now stop worrying about this and declare the actual objects.

The order of definition of the directions affects the way lists come out: the traditional order is N, NE, NW, S, SE, SW, E, W, U, D, IN, OUT.

```
The north is a direction.
The northeast is a direction.
The northwest is a direction.
The south is a direction.
The southeast is a direction.
The southwest is a direction.
The east is a direction.
The west is a direction.
The up is a direction.
The down is a direction.
The inside is a direction.
The outside is a direction.

The north has opposite south. Understand "n" as north.
The northeast has opposite southwest. Understand "ne" as northeast.
The northwest has opposite southeast. Understand "nw" as northwest.
The south has opposite north. Understand "s" as south.
The southeast has opposite northwest. Understand "se" as southeast.
The southwest has opposite northeast. Understand "sw" as southwest.
The east has opposite west. Understand "e" as east.
The west has opposite east. Understand "w" as west.
Up has opposite down. Understand "u" as up.
Down has opposite up. Understand "d" as down.
```

```
Inside has opposite outside. Understand "in" as inside.
Outside has opposite inside. Understand "out" as outside.

The inside object translates into I6 as "in_obj".
The outside object translates into I6 as "out_obj".

The verb to be above implies the mapping-up relation.
The verb to be mapped above implies the mapping-up relation.
The verb to be below implies the mapping-down relation.
The verb to be mapped below implies the mapping-down relation.
```

§**28. Doors.** Doors are, literally, a difficult edge case for the world model of IF, since they occupy the awkward junction between the two different ways of dividing up space: the "vertical" model of objects containing and supporting each other, all within a tree rooted by the room which represents, for the moment, the entire stage-set for the play; and the "horizontal" model of rooms stitched together at compass directions into a map. The difficulty arises because in order for a door to make sense in the horizontal model, it needs to be present in two different rooms at the same time, and then it doesn't make sense in the vertical model any more, because which object tree is it to be in?

```
Section SR1/5 - Doors

The specification of door is "Represents a conduit joining two rooms, most
often a door or gate but sometimes a plank bridge, a slide or a hatchway.
Usually visible and operable from both sides (for instance if you write
'The blue door is east of the Ballroom and west of the Garden.'), but
sometimes only one-way (for instance if you write 'East of the Ballroom is
the long slide. Through the long slide is the cellar.')."
```

§**29.** This is the first kind we have declared to be a kind of something else: a door is a kind of thing. That means a door inherits all of the properties of a thing, but in a way which allows us to change the normal expectations. So here we see the first case of assertions which contradict earlier ones, but in a narrower domain: a thing is usually portable, but a door is usually fixed in place.

Our difficulty with doors being multiply present would be enormously worse if we allowed anybody to move them around during play. So:

```
A door is always fixed in place.
A door is never pushable between rooms.
Include (- has door, -) when defining a door.
```

§**30.** "Every exit is an entrance somewhere else," as Stoppard's play *Rosencrantz and Guildenstern are Dead* puts it: and though not all I7 doors are present on both sides, they do nevertheless have two sides. The representation of this is quite tricky because, as Stoppard implies, it's all a matter of which side you look at it from. What we call the "other side", and whether or not we say that "the Ballroom is through the green door", depends entirely on which side of the green door we stand. The awkward truth is that these expressions are undefined unless the player is in one of the (possibly) two rooms in which the green door is present; and then they are defined relative to him.

The leading-through relation is built in to NI; the other side property, though, is merely a convenient name we give to the property in which the relation data is stored at run-time.

```
A door has an object called other side.
The other side property translates into I6 as "door_to".
Leading-through relates one room (called the other side) to various doors.
The verb to be through implies the leading-through relation.
```

§**31. Containers and supporters.** The carrying capacity property is the exception to the remarks above about the qualitative nature of the world model: here for the first and only time we have a value which can be meaningfully compared.

```
Section SR1/6 - Containers

The specification of container is "Represents something into which portable
things can be put, such as a teachest or a handbag. Something with a really
large immobile interior, such as the Albert Hall, had better be a room
instead."

A container can be enterable.
A container can be opaque or transparent. A container is usually opaque.
A container has a number called carrying capacity.
The carrying capacity of a container is usually 100.

Include (- has container, -) when defining a container.
```

§**32.** The most interesting thing to note here (and we will see it again in the definition of "people") is that "transparent" the I7 property is not a direct match onto `transparent` the I6 attribute. In I7, the term is applicable only to containers (a reform made in January 2008, but clarifying what was already de facto the case). In I6, the `transparent` attribute means that child-objects in the object tree are in scope whenever the parent object is: in the I7 world model that's always true for supporters, so we oblige all supporters to have the attribute `transparent` in their I6 compiled forms. The same will be true for people. That doesn't in practice mean that I7 never has high shelves or people with daggers concealed beneath cloaks – just that we no longer use I6's mechanism for hiding these things, and expect the user to write activity rules instead.

```
Section SR1/7 - Supporters

The specification of supporter is "Represents a surface on which things can be
placed, such as a table."

A supporter can be enterable.
A supporter has a number called carrying capacity.
The carrying capacity of a supporter is usually 100.

A supporter is usually fixed in place.

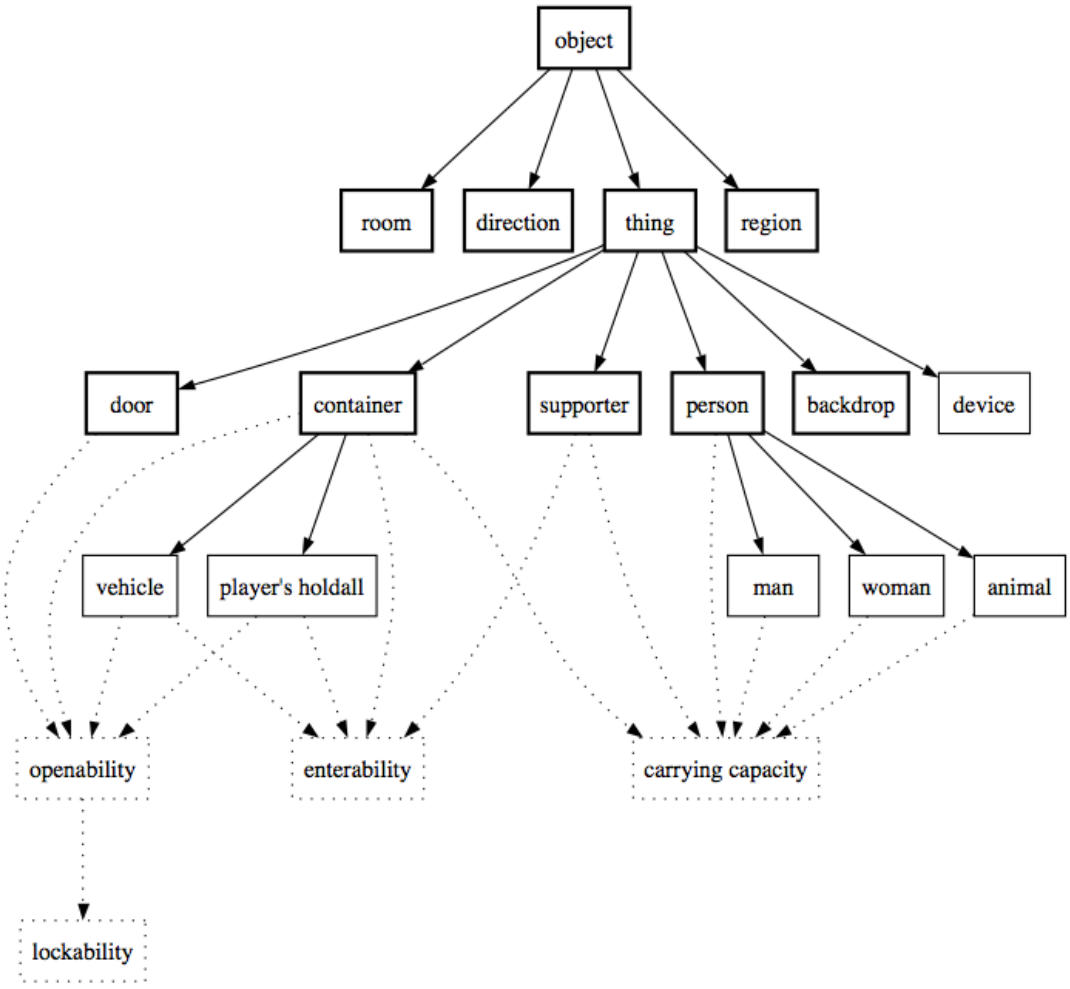
Include (-
    has transparent supporter
-) when defining a supporter.
```

§**33. Kinds vs patterns.** A problem faced by all object-oriented systems is "fear of the diamond", the problematic diagram of inheritance which results when we have two different subclasses B and C of a class A, which represent quite different ideas, but then we also turn out to want some behaviour D which is shared between some of the Bs and some of the Cs. For instance, we might have one class for people and another for buildings, but want to use the same code when it comes to (say) printing out top ten lists of basketball players (people) and skyscrapers (buildings) in height order: why not? But then again, what does D conceptually represent? Surely we aren't saying there's a natural concept of "basketball player/skyscraper"?

There are various responses, of which the most widely used now is probably that of `C++`'s notion of templates. We would define our top-ten business by writing a function applying to a list of objects of any class T such that T provided a height: there would then be no need for "basketball player/skyscraper" to be a class in its own right. Instead, we would define the behaviour as being available to anything for which it makes sense.

This is broadly what Inform 7 does, too, though not so formally. We use the term "pattern" for this, and have actually seen two patterns already – the way that containers and supporters share the "carrying capacity" limit, and also the notion of transparency – and it's by providing two patterns that we are able to deal with the likeness and also unlikeness of doors and containers. Their unlikeness is obvious; but their likeness is that they both grant or withhold access to some extent of space bordering on the current one. (Doors do this for the "horizontal" spatial model between rooms, whereas containers do it for the "vertical" spatial model of objects enclosing each other.)

The following diagram shows the kinds created by the Standard Rules (bold boxes for fundamental kinds, plain ones for discretionary additions) and the patterns of behaviour they share (dotted boxes).



§**34. The openability pattern.** To satisfy the openability pattern, a thing has to provide both of the either/or properties "open" and "openable". This entitles it to be opened and closed by the opening and closing actions, defined below. Note that I7 has no formal concept of patterns as part of its type-checking: instead, the rules for these actions explicitly check that they are being applied to things matching the pattern, as we shall see.

Doors and containers have, as it happens, exactly opposite conventions about the default values of these properties: but that doesn't mean they don't share the pattern.

```
Section SR1/8 - Openability

A door can be open or closed. A door is usually closed.
A door can be openable or unopenable. A door is usually openable.

A container can be open or closed. A container is usually open.
A container can be openable or unopenable. A container is usually unopenable.
```

§**35. The lockability pattern.** And similarly for lockability, because a principle of the world model is that any spatial barrier can be given a lock if the designer so chooses. To satisfy this pattern, a thing must

(i) satisfy the openability pattern, and
(ii) provide both the either/or properties "lockable" and "locked", and also the value property "matching key".

Both doors and containers make some implications so that the words "lockable" and "locked" carry the implied meanings which human readers expect, but this is not essential to the functioning of lockability: it's only a graceful addition.

```
Section SR1/9 - Lockability

A door can be lockable. A door is usually not lockable.
A door can be locked or unlocked. A door is usually unlocked.
A door has an object called a matching key.
A locked door is usually lockable. [An implication.]
A locked door is usually closed. [An implication.]
A lockable door is usually openable. [An implication.]

A container can be lockable. A container is usually not lockable.
A container can be locked or unlocked. A container is usually unlocked.
A container has an object called a matching key.
A locked container is usually lockable. [An implication.]
A locked container is usually closed. [An implication.]
A lockable container is usually openable. [An implication.]
```

§**36.** Note that the lock-fitting relation has, as its domains, "thing" and "thing". That means that compile-time typechecking will not reject an attempt to apply the relation to (say) two vehicles. At run time, evaluating "if X unlocks P" where P is a peculiar thing with no possibility of a lock will always come out false; but trying to force it with "now X unlocks P" will cause a run-time problem. In short, patterns are defended at run-time, not at compile-time.

```
Lock-fitting relates one thing (called the matching key) to various things.
The verb to unlock (it unlocks, they unlock, it unlocked, it is unlocked)
implies the lock-fitting relation.
```

§**37. Backdrops.** The true subtlety of backdrops is not visible in the brief description here: but they require careful handling both in NI and in the template layer code, because they can be in many rooms at once.

```
Section SR1/10 - Backdrops

The specification of backdrop is "Represents an aspect of the landscape
or architecture which extends across more than one room: for instance,
a stream, the sky or a long carpet."

A backdrop is usually scenery.
A backdrop is always fixed in place.
A backdrop is never pushable between rooms.
```

§**38. People.** From a compilation point of view, people are surprisingly easy to deal with. It may well be argued that this is because the I6 world model is so sketchy in modelling them, but that may actually be a good thing, because it's not at all obvious that any single model will be sensible for what different authors want to do with their characters.

On gender, see also the "man" and "woman" kinds below. Note that we have three gender choices available – male, female and neuter – but these are, for historical reasons to do with how gender is handled by the I6 library, managed using either/or properties rather than a single three-way value property. This doesn't in practice cause trouble. (Specifying something as neuter overrides the male/female choice, if anyone does both for the same object, but in practice nobody does.) When nothing is said about a person's gender, it is assumed male, though this is used only linguistically (for instance, the pronoun HIM can be used in commands about the object, rather than HER or IT). There has to be some convention here, and in a case where we don't know our linguistic ground, opting for the least surprising behaviour seems wisest.

```
Section SR1/11 - People

The specification of person is "Despite the name, not necessarily
a human being, but anything animate enough to envisage having a
conversation with, or bartering with."

A person can be female or male. A person is usually male.
A person can be neuter. A person is usually not neuter.

A person has a number called carrying capacity.
The carrying capacity of a person is usually 100.
```

§**39.** I6 has a concept approximately equivalent to I7's "person" – the I6 library attribute `animate` – but I6 allows only some of those objects to become the protagonist during play (using I6's `ChangePlayer` routine). To be eligible, an object must not only be `animate` but also provide a whole host of writeable properties.

But I7 provides those I6 properties for every "person", for the sake of a clean, uniform design, and accepting the cost that people therefore take more bytes of precious Z-machine array space than they necessarily would in I6. This is all part of the doctrine that in I7, all characters are equal in status: all can be the player, all can carry out actions. Anyway: here are all of those I6 properties, spatchcocked into the `Class` definition which NI will compile for "person" – see §21 of the DM4 for details of why these are needed and what they do.

```
Include (-
    has transparent animate
    with before NULL, ! number 0,
-) when defining a person.
```

§**40.** So to the thirteenth and final object created by the Standard Rules: the enigmatic default protagonist, whose name is not "player" but "yourself". (The I6 library requires this object to be created as `selfobj`, but that's not a name that is ever printed or parsed: it's a constant value used only in I6 source code.)

The `yourself` object has to be proper-named to prevent the I6 library from talking about "the yourself", as it otherwise might. "Undescribed" in this context means that "yourself" is not described as being present in room descriptions: this would be redundant and annoying.

The I6 property `saved_short_name` property is an implementation convenience for use if there is ever a change of player, in which case the printed name of the object will cease to be "yourself" and become "your former self" instead. When this happens, the previous printed name (or `short_name` in I6 terms) is stored in `saved_short_name` so that it can recovered later. (We can't assume it was necessarily "yourself" because the source text might have overridden this with a sentence like "The printed name of the player is "your dreary self".")

```
The yourself is an undescribed person. The yourself is proper-named.

The description of yourself is usually "As good-looking as ever."

The yourself object translates into I6 as "selfobj".
Include (-
    has proper,
    with saved_short_name "yourself",
-) when defining yourself.
```

§**41. Non-fundamental kinds.** We have now finished defining the nine fundamental kinds which NI requires in order for it to function. There are six more to define, but it's worth emphasising that none of these are required or assumed by either NI or its template layer of I6 code. So any of them could be changed drastically or got rid of entirely simply by amending the Standard Rules. (Like the "player-character" kind, born early 2003, died July 2007.)

Equally, we could add others if we wanted. The judgement of what ought to be part of the basic hierarchy of kinds created by the Standard Rules isn't easy. The maximalist position is that users welcome a plethora of kinds to simulate many facets of real life, from canal-boats to candles. The minimalist position is that kinds are necessary only as the domain of relations (so that person is necessary as the domain of P in "P carries X", for instance), and that too many kinds confuses the picture and imposes what may be a constraining structure on the user, who should be free to decide for himself what concepts are most helpful to organise. These arguments are discussed further in the white paper, *Natural Language, Semantic Analysis and Interactive Fiction* (2005), but briefly: we are minimalist but not puritanically so.

§**42. Men, women and animals.** Of these discretionary kinds, so to speak, "man" and "woman" are perhaps the least challengeable. They are not obviously the domains of any natural relation (unless one takes a very old-fashioned idea of gender identity and supposes that, oh, "X keeps Y" implies that X is a wealthy man and Y a mistress). But they are so linguistically natural in story-telling: who would ever write "Jack is a person in the House. Jack is male." in preference to "Jack is a man in the House."

An awkward point here is that, of course, most people would simply say "Jack is in the House." and expect us to infer that Jack is a person from the fact that this is more often a human name than, say, a proprietary brand of microphone plug; and that Jack is male, because relatively few girls called Jacqueline are nicknamed Jack. As it happens the NI compiler doesn't allow for tentative statements about the kinds of objects (only about their property values), but it wouldn't be too hard to add such a system, with a little care. The trouble is that we would then need a large dictionary of boys' and girls' names, valid across American, Canadian, Australian and British English (together with a selection from foreign tongues), and this would always lead to puzzling omissions (why isn't "Glanville" recognised?) or ambiguities (why is "Pat" a man?). And similarly for titles: "Mr", "Mrs" and "Ms" are fairly indicative of gender, except in certain military contexts, but what about (say) "Admiral" or "Reverend", where there is a strong likelihood of masculinity but no more than that? So Inform 7's compromise position is that the user does have to specify gender

explicitly, but that the kinds "man" and "woman" provide conveniently abbreviated ways to do so. (We consider male and female children to qualify in these categories.)

Anyway, we set out the Anglo-Saxon plurals, and then declare these kinds purely in terms of gender: they have no distinguishing behaviour.

```
Section SR1/12 - Animals, men and women

The plural of man is men. The plural of woman is women.

A man is a kind of person.
The specification of man is "Represents a man or boy."
A man is always male. A man is never neuter.

A woman is a kind of person.
The specification of woman is "Represents a woman or girl."
A woman is always female. A woman is never neuter.
```

§**43.** But what about "animal"? Animals turn up often in IF, and of course domestic animals have been part of human society since prehistoric times: but then again, the same can be said for stoves and larders, and we aren't declaring kinds for those.

The reason "animal" exists is mainly because it is almost always peculiar to write "P is a person". Now that we have "man" and "woman" taken care of, the remaining objects we might want to declare will almost always fall into this category: it's intended to be used for "people" who are animate but probably not intelligent, or anyway, not participants in human society. It seems unusual to write "The black Labrador is a person." because that sounds like an insistent assertion of rights and thus a quite different sort of statement. (Don't drown that Labrador! He's a *person*.)

As can be seen from the tiny definition of "animal", though, it's really nothing more than a name for a position in the kinds hierarchy. There is not even any implication for gender.

```
An animal is a kind of person.

The specification of animal is "Represents an animal, or at any rate a
non-human living creature reasonably large and possible to interact with: a
giant Venus fly-trap might qualify, but not a patch of lichen."
```

§**44. Devices.** The justification for providing a "device" kind is much thinner. It's done largely for traditional reasons – such a concept existed in the I6 library, which in turn followed Infocom conventions dating from the early 1980s. The inclusion is defensible as representing a common linguistic category found in everyday situations, where an inanimate object nevertheless does something while under direct or indirect human control: we can also imagine relations for which it could be a domain ("X is able to work D" meaning that person X understands how to use the controls of device D, say). It could equally be attacked as having a rather flimsy world model – it's just an on/off switch – and representing a pretty inchoate mass of concepts, from a mousetrap to a nuclear reactor.

```
Section SR1/13 - Devices

A device is a kind of thing.

A device can be switched on or switched off. A device is usually switched off.
Include (- has switchable, -) when defining a device.

The specification of device is "Represents a machine or contrivance of some
kind which can be switched on or off."
```

§**45. Vehicles.** Here again the justification boils down to tradition. Vehicles were a staple ingredient of the Infocom classics, largely because of code originally written for the inflatable boat in the 1978-79 mainframe version of *Zork*, which was then copied through into later titles. Unlike devices, though, vehicles are genuinely difficult to model, and the implementation provided by the Standard Rules would be quite a lot of work for a user to manage alone. (Consider, for instance, the case when the player is sitting in an open basket when Bill, driving a fork-lift truck, uses his vehicle to push the basket into another room.) There might perhaps be a case for moving all of the vehicles material into an extension, but it would have to be an extension supplied as part of the built-in set, and whenever it was used the result would be that the going action would rely on a pretty complicated interlacing of rules as between this extension and the Standard Rules.

Turning to implementation, I6 – surprisingly, perhaps – doesn't have a `vehicle` attribute: a vehicle is an object which is `enterable` and whose `before` rule for the I6 `##Go` action returns the magic value 1. A troublesome point here is that I6 makes no distinction between vehicles which contain and vehicles which support. But we do, because once we have decided to make "vehicle" a kind, it has to be either a kind of container or a kind of supporter: it can't be both. We get around this by providing for container-vehicles in the Standard Rules, as being the more commonly occurring case, while providing for the other with the extension Rideable Vehicles by Graham Nelson, which is in effect an offshoot of the Standard Rules and is built-in to every installation of Inform 7. This also provides for animals used as vehicles.

The alternative approach here would be to make "vehicle" not a kind but an either/or property of things, so as to provide a pattern of behaviour common to certain animals, containers and supporters. We could then move Rideable Vehicles back into the Standard Rules, but that would add a fair amount of code, and besides, it is unclear that "vehicleness" is something we want to come and go during play, or that it's appropriate as an either/or property of (for instance) a door or a person.

```
Section SR1/14 - Vehicles

A vehicle is a kind of container.

The specification of vehicle is "Represents a container large enough for
a person to enter, and which can then move between rooms at the driver's
instruction. (If a supporter is needed instead, try the extension
Rideable Vehicles by Graham Nelson.)"

A vehicle is always enterable.
```

§**46.** The part about vehicles not usually being portable is simply for realism's sake: generally speaking if something can hold human weight it's pretty large and heavy. (A bicycle is an edge case, and a skateboard is clearly an exception, but that's why the rule is only "usually".)

If all vehicles were wheeled, there would be a case for a rule such as "A vehicle is usually pushable between rooms." But this seems more likely to trip up the designer with a surprise discovery in beta-testing than to help him achieve realism. We don't want to be able to push hot-air balloons, boats or spacecraft between rooms.

```
A vehicle is usually not portable.
```

§**47. Player's holdalls.** This is the final kind created in the Standard Rules, and probably the most doubtful of all. It simply provides a hook to a cute and traditional feature of the I6 library whereby spare possessions are automatically cleared out of the player's way: it derives from the rucksack in the 1993 IF title *Curses*.

```
Section SR1/15 - Player's holdall

A player's holdall is a kind of container.

The specification of player's holdall is "Represents a container which the
player can carry around as a sort of rucksack, into which spare items are
automatically stowed away."

A player's holdall is always portable.
A player's holdall is usually openable.
```

§**48.** To enable the use of player's holdalls, we must declare a constant `RUCKSACK_CLASS` to tell some code in the template layer to use possessions with this I6 class as the rucksack pro tem. This is all a bit of a hack, to retrofit a degree of generality onto the original I6 library feature, and even then it isn't really fully general: only the player has the benefit of a "player's holdall" (hence the name), with other actors oblivious.

```
Include (-
    Constant RUCKSACK_CLASS = (+ player's holdall +);
-) after "Definitions.i6t".
```

§**49. Correspondence between I6 and I7 property and attribute names.** All of the kinds, objects and properties which make up the standard kit provided to every source text are now complete. We conclude Section SR1 by giving the NI compiler a dictionary to tell it how I7's names for properties – some value properties, some either/or – mesh with those in the I6 library.

Ordinarily, a new value property such as "astral significance" would be compiled by NI into an I6 property called something like

```
P73_astral_significance
```

whereas a new either/or property might become either an I6 attribute or an I6 property holding only `true` or `false`, at the compiler's discretion. (It needs to use this discretion because I6 has a hard limit on the number of attributes, whereas there are no limits on the number of properties used in I7.) And if "astral significance" is a concept handled only by I7 source text, that's fine.

But we want our "printed name" property, for instance, to be the text which the I6 library prints out whenever it uses the `short_name` of an object: so we want the NI compiler to use the I6 identifier `short_name` for "printed name", not to invent a new one. NI therefore maintains a dictionary of equivalents, and here it is. (Any I7 property not named is handled purely by I7 source text in the remainder of the Standard Rules.)

§**50.** First, equivalents where I7 either/or properties map directly onto I6 attributes. Note the way "lit" (for things) and "lighted" (for rooms) both map onto the same I6 attribute, `light`. Attributes were in scarce supply in I6 (with a limit of 32 in the early days, later raised to 48) and this sort of reuse seemed sensible in the early 1990s, especially as the meanings were basically similar.

```
Section SR1/16 - Inform 6 equivalents

The wearable property translates into I6 as "clothing".
The undescribed property translates into I6 as "concealed".
The edible property translates into I6 as "edible".
The enterable property translates into I6 as "enterable".
The female property translates into I6 as "female".
The initially carried property translates into I6 as "initially_carried".
The mentioned property translates into I6 as "mentioned".
The lit property translates into I6 as "light".
The lighted property translates into I6 as "light".
The lockable property translates into I6 as "lockable".
The locked property translates into I6 as "locked".
The handled property translates into I6 as "moved".
The neuter property translates into I6 as "neuter".
The switched on property translates into I6 as "on".
The open property translates into I6 as "open".
The openable property translates into I6 as "openable".
The privately-named property translates into I6 as "privately_named".
The plural-named property translates into I6 as "pluralname".
The proper-named property translates into I6 as "proper".
The pushable between rooms property translates into I6 as "pushable".
The scenery property translates into I6 as "scenery".
The fixed in place property translates into I6 as "static".
The transparent property translates into I6 as "transparent".
The visited property translates into I6 as "visited".
The marked for listing property translates into I6 as "workflag".
```

§**51.** Second, the I7 value properties mapping onto I6 properties. Again, `map_region` is a new I6 property of our own, while the rest are I6 staples. And see also "other side", which is translated above for timing reasons.

```
The indefinite article property translates into I6 as "article".
The carrying capacity property translates into I6 as "capacity".
The description property translates into I6 as "description".
The initial appearance property translates into I6 as "initial".
The map region property translates into I6 as "map_region".
The printed plural name property translates into I6 as "plural".
The printed name property translates into I6 as "short_name".
The matching key property translates into I6 as "with_key".
```

SR2 - Variables and Rulebooks A/sr2

Purpose

The global variables and those built-in rulebooks which do not belong either to specific actions or to specific activities.

---

§**1.** With the kinds, objects and properties all now made, we turn to more abstract constructions: rules, rulebooks, activities, global variables and so on. As at the beginning of Part SR1 above, we begin with an entirely clean slate – none of any of these things exists yet – but also with expectations on what we do, since NI and the I7 template layer need certain constructions to be made.

We begin with global variables. The order in which these are defined, and the section subheadings under which they are grouped, determine the way they are indexed in the Contents index of a project – that is, moving them around would reorder the Contents index, and rewording the subheadings SR2/1, SR2/2, ..., below would change the text of the subheadings in the Contents index accordingly.

Some of these variables are special to NI, and it knows which they are not by the order in which they're defined (as with kinds, above) but by their (I7) names. These are marked with the comment `[*]`, and cannot be renamed without altering NI to match. Those marked `[**]` are similarly named in the template layer.

§**2.** It's now the occasion for our first global variable definition, because although users often think of the protagonist object as a fixed object whose name is "player", it's in fact possible to change perspective during play and become somebody else – at which point the "player" variable will point to a different object.

Note that "player" is actually a variable belonging to the I6 library, as indeed most of those in the Standard Rules are. Without the explicit translation supplied below, it would probably be compiled as `Q1_player` or some such name; and might well be implemented by NI as an entry in an array (since the Z-machine supports only a limited number of global variables, in effect using them as a set of 240 registers, and we therefore don't want to create too many ourselves).

```
Part SR2 - Variables and Rulebooks

Section SR2/1 - Situation

The player is a person that varies. [*]
The player variable translates into I6 as "player".
```

§**3.** The I7 variable "location" corresponds to I6's `real_location`, not `location`. Its value is never equal to a pseudo-room representing darkness: it is always an actual room, and I7 has nothing corresponding to I6's `thedark` "room". Similarly, we use an I7 variable "darkness witnessed" for a flag which the I6 library would have stored as the `visited` attribute for the `thedark` object.

The "maximum score" is, rather cheekily, translated to an I6 constant: and this cannot be changed at run-time.

```
The location -- documented at var_location -- is an object that varies. [*]
The score -- documented at var_score -- is a number that varies.
The last notified score is a number that varies.
The maximum score is a number that varies. [*]
The turn count is a number that varies.
The time of day -- documented at var_time -- is a time that varies. [*]
The darkness witnessed is a truth state that varies.

The location variable translates into I6 as "real_location".
The score variable translates into I6 as "score".
The last notified score variable translates into I6 as "last_score".
The maximum score variable translates into I6 as "MAX_SCORE".
The turn count variable translates into I6 as "turns".
The time of day variable translates into I6 as "the_time".
```

§**4.** It is arguable that "noun", "second noun" and "person asked" ought to be rulebook variables belonging to the action-processing rules, so that they essentially did not exist outside of the context of an ongoing action. The reason this isn't done is partly historical (rulebook variables were a fairly late development, implemented in April 2007, though they had long been planned). But it is sometimes useful to get at the nouns in an action after it has finished, and making them global variables also makes them a little faster to look up (a good thing since they are used so much), and causes them to be indexed more prominently.

"Item described" is simply an I7 name for `self`. (In an object-oriented system such as I6, `self` is the natural way to refer to the object currently under discussion, within routines applying to all objects of its class.) In early drafts of I7, it was called "this object", but somehow this raised expectations too high about how often it would be meaningful: it looked like a pronoun running meanings from sentence to sentence.

```
Section SR2/2 - Current action

The noun -- documented at var_noun -- is an object that varies. [*]
The second noun is an object that varies. [*]
The person asked -- documented at var_person_asked -- is an object that varies. [*]
The reason the action failed -- documented at var_reason -- is a rule that varies.
The item described is an object that varies.

The noun variable translates into I6 as "noun".
The second noun variable translates into I6 as "second".
The person asked variable translates into I6 as "actor".
The reason the action failed variable translates into I6 as "reason_the_action_failed".
The item described variable translates into I6 as "self".
```

§**5.** "Person reaching" turns out to have exactly the same meaning as "person asked" – they are both the `actor`, in I6 terms, but are used in different situations.

```
Section SR2/3 - Used when ruling on accessibility

The person reaching -- documented at var_person_reaching -- is an object that varies.
The container in question is an object that varies.
The supporter in question is an object that varies.
The particular possession -- documented at var_particular -- is a thing that varies.

The person reaching variable translates into I6 as "actor".
The container in question variable translates into I6 as "parameter_object".
The supporter in question variable translates into I6 as "parameter_object".
The particular possession variable translates into I6 as "particular_possession".
```

§**6.** Parsing variables follow. The I6 parser tends to put any data read as part of a command into the variable `parsed_number`, but then, I6 is typeless: we can't have a single I7 variable for all these possibilities since it could then have no legal type. We solve this as follows. Whenever a kind of value K is created which can be parsed as part of a command, an I7 variable "the K understood" is also created, as a K that varies. All of these variables are translated into I6's `parsed_number`, so in effect they provide aliases of each possible type for the same underlying memory location. The four exceptional kinds of value not parsed by the systematic approaches in NI for enumerated KOVs and units are "number", "time", "snippet" and "truth state": because of their exceptional status, they don't get "the K understood" variables created automatically for them, so we must construct those by hand. Hence "the number understood", "the time understood", "the topic understood" (for historical reasons this one is not called "the snippet understood"), "the truth state understood" but no others.

```
Section SR2/4 - Used when understanding typed commands

The player's command -- documented at var_command -- is a snippet that varies.
The matched text is a snippet that varies.
The number understood -- documented at var_understood -- is a number that varies. [*]
The time understood is a time that varies. [*]
The topic understood is a snippet that varies. [*]
The truth state understood is a truth state that varies. [*]
The current item from the multiple object list is an object that varies.

The player's command variable translates into I6 as "players_command".
The matched text variable translates into I6 as "matched_text".
The topic understood variable translates into I6 as "parsed_number".
The truth state understood variable translates into I6 as "parsed_number".
The current item from the multiple object list variable translates into I6 as
    "multiple_object_item".
```

§**7.** The following are, unless the user creates global variables of his own, the last in the Contents index...

```
Section SR2/5 - Presentation on screen

The command prompt -- documented at var_prompt -- is a text that varies. [**]
The command prompt is ">".

The left hand status line -- documented at var_sl -- is a text that varies.
The right hand status line is a text that varies.

The left hand status line variable translates into I6 as "left_hand_status_line".
The right hand status line variable translates into I6 as "right_hand_status_line".

The listing group size is a number that varies.
The listing group size variable translates into I6 as "listing_size".
```

§**8.** ...but they are not the last global variables created by the Standard Rules.

These bibliographic data variables are concealed because they are under a heading which ends with the word "unindexed". There are two reasons why these variables are unindexed: first, they appear in a different guise only a little lower in the Contents index as part of the Library Card, and second, we don't want users to think of them as manipulable during play.

Rather sneakily, we also define a Figure here. This is done in order to make it legal to declare variables and properties of the kind of value "figure-name" (because it ensures that such variables can always be initialised – there is always at least one Figure in the world). Of course plenty of Inform projects have no artwork at all: so the cover art figure is unique in that it might refer to nothing. That sounds a little arbitrary but in fact follows a convention used by the Blorb format for binding story files with their resources, which in turn follows Infocom conventions of 1987-89: the cover art always has resource ID number 1, whether it exists or not. NI creates figures and sound effects counting upwards from 1, giving them each unique resource ID numbers, so the first to be created gets ID number 1: by defining "figure of cover" here, we can be sure that we are first, so everything works.

```
Section SR2/6 - Unindexed Standard Rules variables - Unindexed

The story title, the story author, the story headline, the story genre
and the story description are text variables. [*****]
The release number and the story creation year are number variables. [**]
Figure of cover is the file of cover art.

The story title variable translates into I6 as "Story".
```

§**9.** And we finish out the set with some "secret" variables used only by the Standard Rules or by NI, and which are therefore also unindexed. Their names are all hyphenated, to reduce the chance of anyone stumbling into them in a namespace clash.

The first set of three secret variables is used by the predicate calculus machinery in NI. This is the code which handles logical sentences such as "at least six doors are open" or descriptions such as "open doors", by reducing them to a logical notation which sometimes makes use of variables. For instance, "open doors" reduces to something like "all x such that door(x) and open(x)", with x being a variable. When NI works with such logical propositions, it often needs to substitute $x = c$, that is, to replace x with a given constant c. But it can only do this if c is an Inform 7 value. This is a problem if what it wants is to substitute in something which is only meaningful at the I6 level: say, it wants to substitute a value c which will eventually translate to `whatever`, but it can't find any I7 value c which will do this.

We solve this problem by constructing some unusual I7 variables whose only purpose is that NI can use them in substitutions. They should never be referred to in I7 source text anywhere else at all, not even elsewhere in the Standard Rules.

(1) The "substitution-variable" is used when NI needs to compile a proposition with one free variable, such as "door(x)", as a condition: it binds x with the substitution $x =$ *say-parameter* in order to turn this into a well-formed predicate calculus sentence with no free variables, then compiles it. This is a trick used in the definition of some of the "repeat" phrases below, as a result of the `{-bind-variable:...}` invocation command.

(2) The sentence "The i6-nothing-constant is an object that varies." is a rare example of a flat lie in the Standard Rules, as it is the I6 constant `nothing` and never varies at all. Again, it exists as a "variable" so that the substitution $x =$ `nothing` can be made.

(3) Well, once you start telling lies it's so hard to stop, and it's also a lie that the "I6-varying-global" translates to `nothing`. It actually translates to whatever the NI machinery for compiling propositions happens to want at the moment, so it has no permanent meaning at all. (It will always translate to an I6 global variable storing a value whose I7 kind is "object", so the type-checking machinery isn't endangered by this chicanery. It will in fact never translate to `nothing`, but we make the translation sentence below in order to avoid allocating any storage at run-time for what is in the end only a label.)

```
The substitution-variable is an object that varies. [*]
The substitution-variable variable translates into I6 as "subst__v".

The I6-nothing-constant is an object that varies. [*]
The I6-nothing-constant variable translates into I6 as "nothing".

The I6-varying-global is an object that varies. [*]
The I6-varying-global variable translates into I6 as "nothing".
```

§**10.** The remaining secret variables are:

(1) The "item-pushed-between-rooms" is needed to get the identity of an object being pushed by a command like PUSH ARMCHAIR NORTH out of I6 and into the action variable "thing gone with" of the going action.

(2) The "actor-location" is needed temporarily to store the room in which the actor of the current action is standing, and it wants to be an I6 global (rather than, say, a rulebook variable belonging to the action-processing rulebook) so that NI can use common code to handle this alongside `noun`, `second` and `actor` when compiling preambles to rules.

(3) The "parameter-object" is likewise needed in order to compile preambles to rules in object-based rulebooks.

```
The item-pushed-between-rooms is an object that varies.
The item-pushed-between-rooms variable translates into I6 as "move_pushing".

The actor-location is an object that varies. [*]
The actor-location variable translates into I6 as "actor_location".

The parameter-object is an object that varies. [*]
The parameter-object variable translates into I6 as "parameter_object".
```

§**11.** And that completes the run through all the variables created in the Standard Rules.

§**12. Rulebooks.** There are 25 rulebooks which are, so to speak, "primitive" in Inform 7 – which are part of its workings and cannot safely be tampered with. NI requires them to be declared by the Standard Rules as the first 25 rulebooks to be created, and in the exact order below. (In fact, though, this is mostly so that it can prepare the index pages correctly: NI is not the part of I7 which decides what to use these rulebooks for. That is almost always the responsibility of the template I6 layer which, for instance, calls upon the action-processing rulebook when it wants an action processed.)

At the I6 level, a rulebook is referred to by its ID number, which counts upwards from 0 in order of creation. Any reordering of the constants below, therefore, is unsafe unless changes are made elsewhere so that the following three tallies always remain in synchrony:

(a) The sequence of declaration of these rulebooks in the Standard Rules.
(b) The inweb `@d` definitions in the form `TURN_SEQUENCE_RB` in the section Rulebooks of Chapter 12 of the NI source code.
(c) The I6 `Constant` definitions in the form `TURN_SEQUENCE_RB` in the file `Rulebooks.i6t` of the template I6 layer.

Anyway, we will declare the rulebooks and their variables or outcomes first, and come back to stock some of them with rules later. It seems appropriate to give first place to the procedural rules, the super-rulebook capable of controlling all others:

```
Section SR2/7 - The Standard Rulebooks

Procedural rules is a rulebook. [0]
```

§**13.** Every story file created by Inform 6 begins execution in a routine called `Main`, which is analogous to the `main()` function of a C program: it is as if the entire program is a call to this function.

In an I7 story file, the code in `Main` is the only code which is not executed in the context of a rulebook, and by design it does as little as possible. The definition is in part "Main" of "OrderOfPlay.i6t", and this is what it does:

(1) Consider the startup rules.
(2) Repeatedly follow the turn sequence rules until `deadflag` is set, which is an I6 variable used to indicate that the game has ended in one way or another.
(3) Follow the shutdown rules.

The startup rules are only considered, not followed, because we cannot risk a procedural rule being the first thing executed: starting up the virtual machine correctly has to be our first priority. (Except for not using the procedural rules, considering a rulebook is identical to following it.)

Briefly, the startup phase takes us to the end of the room description after the banner is printed. The turn sequence covers a complete turn, and runs through from prompting the player for a command to notifying him of any change in score which occurred. The shutdown rules then go from printing the obituary text, through final score, to the question about quitting or restarting.

```
Startup rules is a rulebook. [1]
Turn sequence rules is a rulebook. [2]
Shutdown rules is a rulebook. [3]
```

§**14.** Now a set of rulebooks to do with the passage of time.

```
Scene changing rules is a rulebook. [4]
When play begins is a rulebook. [5]
When play ends is a rulebook. [6]
Every turn rules is a rulebook. [7]
```

§**15.** The action machinery requires some 16 rulebooks to work, though that is the result of gradual simplification – in 2006 it required 25, for instance. The "action-processing" rulebook, like the turn sequence rulebook, is a master of ceremonies: it belongs to the Standard Rules and is only rarely if at all referred to by users.

As remarked above, it's something of a historical accident that "actor" is a rulebook variable belonging to the action-processing rules (and thus in scope for every rulebook it employs) while "noun" and "second noun" are global variables (and thus in scope everywhere).

The main action-processing rulebook delegates most of its detailed work to a subsidiary, the "specific action-processing" rulebook, at the point where what rulebooks we consult next depends on what the action is (hence "specific") – see below for more on how check/carry out/report rules are filed.

```
Action-processing rules is a rulebook. [8]
The action-processing rulebook has a person called the actor.
Setting action variables is a rulebook. [9]
The specific action-processing rules is a rulebook. [10]
The specific action-processing rulebook has a truth state called action in world.
The specific action-processing rulebook has a truth state called action keeping silent.
The specific action-processing rulebook has a rulebook called specific check rulebook.
The specific action-processing rulebook has a rulebook called specific carry out rulebook.
The specific action-processing rulebook has a rulebook called specific report rulebook.
The specific action-processing rulebook has a truth state called within the player's sight.
The player's action awareness rules is a rulebook. [11]
```

§**16.** The rules on accessibility and visibility, which control whether an action is physically possible, have named outcomes as a taste of syntactic sugar.

```
Accessibility rules is a rulebook. [12]
Reaching inside rules is an object-based rulebook. [13]
Reaching inside rules have outcomes allow access (success) and deny access (failure).
Reaching outside rules is an object-based rulebook. [14]
Reaching outside rules have outcomes allow access (success) and deny access (failure).
Visibility rules is a rulebook. [15]
Visibility rules have outcomes there is sufficient light (failure) and there is
insufficient light (success).
```

§**17.** Two rulebooks govern the processing of asking other people to carry out actions:

```
Persuasion rules is a rulebook. [16]
Persuasion rules have outcomes persuasion succeeds (success) and persuasion fails (failure).
Unsuccessful attempt by is a rulebook. [17]
```

§**18.** Next, the six classic rulebooks best known to users of Inform. It's perhaps an unfortunate point of the design that there are so many as six: that seems rather a lot of stages to go through, and indeed means that there is sometimes some ambiguity about which rulebook to use if one wants to achieve a given effect. There are really two reasons why things are done this way:

(a) To try to encourage a distinction between:

(i) the general implementation of an action, made with carry out, check and report rules – say, a "photographing" action which could be used in any situation and could be copied and pasted into another project; and

(ii) the contingent rules applying in particular situations in play, made with before, instead and after rules, such as that custodians at the Metropolitan Museum of Art forbid flash photography.

(b) To improve the efficiency of action-processing by forcing control to run only through those carry out, check and report rules which can possibly be relevant to the current action. Whereas all before, instead and after rules are all piled up together in their own rulebooks, check, carry out and report rules are divided up into specialised rulebooks tied to the particular action in progress. Thus on a taking action, the six stages followed are before, instead, check taking, carry out taking, after and report taking.

During play, then, the three rulebooks "check", "after" and "report" are completely empty. This is the result of a reform in April 2007 which wasn't altogether popular. Before then, NI rather cleverly filed rules like "Check doing something with the haddock" in the generic "check" rulebook and ran this rulebook as part of the action processing sequence. But this clearly broke principle (i) above, and meant that the six-stage process – already quite complicated enough – was actually a nine-stage process only pretending, by deceitful syntax, to be a six-stage one. Check rules sometimes appeared to be filed in the wrong order, breaking the ordinary precedence conventions, and this was not due to a bug but because they were only pretending all to be in the same rulebook. Still more clever indexing and rule-ordering tricks ameliorated this a little, but in the end it was just a bad design: withdrawing the ability to make check, carry out and report rules apply to multiple actions resulted in much cleaner code, and also a clearer conceptual definition of what these rulebooks were for. (But users still *didn't* like the change: actual functionality was withdrawn.)

So if they are always empty and never used, why are the three rulebooks called simply "check", "after" and "report" created in the first place? The answer is that this is a convenience for parsing rule preambles in NI: it provides a temporary home for such rules before they are divided up into their specific rulebooks, and it also makes it easier for NI to detect and give a helpful Problem message in response to rules like "Check taking or dropping the perch" which can't be filed anywhere in our scheme, and so have to be forbidden.

```
Before rules is a rulebook. [18]
Instead rules is a rulebook. [19]
Check rules is a rulebook. [20]
Carry out rules is a rulebook. [21]
After rules is a rulebook. [22]
Report rules is a rulebook. [23]
```

§**19.** The final rulebook in this roundup is one used for parsing ambiguous commands during play. This looks like the job of an activity rather than a rulebook, but (i) we want information in the form of a nicely-named five point scale of responses, rather than wanting something to be done, and (ii) it doesn't really make any sense to split that question into a before, for and after stage. So this is a named rulebook instead.

```
The does the player mean rules are a rulebook. [24]
The does the player mean rules have outcomes it is very likely, it is likely, it is possible,
it is unlikely and it is very unlikely.
```

§**20.** "Does the player mean" is essentially a front end for the I6 parser's `ChooseObjects` entry point, which relies on numerical scores to assess the likelihood of possible choices. That makes it useful to have an I6 wrapper function which consults the "does the player mean" rulebook, translates the named outcomes into a score from 0 to 4, and returns that. Note that if the rulebook makes no decision and has no outcome, we return the middle-of-the-road value 2. (This wrapper routine looks as if it belongs in the template I6 layer, but having it here allows it to use the `(+` and `+)` escapes.)

```
Include (-
    [ CheckDPMR result sinp1 sinp2 rv;
        sinp1 = inp1; sinp2 = inp2; inp1 = noun; inp2 = second;
        rv = FollowRulebook( (+does the player mean rules+) );
        inp1 = sinp1; inp2 = sinp2;
        if ((rv) && RulebookSucceeded()) {
            result = ResultOfRule();
            if (result == (+ it is very likely outcome +) ) return 4;
            if (result == (+ it is likely outcome +) ) return 3;
            if (result == (+ it is possible outcome +) ) return 2;
            if (result == (+ it is unlikely outcome +) ) return 1;
            if (result == (+ it is very unlikely outcome +) ) return 0;
        }
        return 2;
    ];
-);
```

§**21.** And that's it: all 25 of the named rulebooks now exist. There will, of course, be hundreds more rulebooks soon, created automatically as activities and actions are created – when we create the "dropping" action, for instance, we also create the "check dropping", "carry out dropping" and "report dropping" rulebooks – but there are no more stand-alone rulebooks.

§**22. Rules.** At run-time, the value of a rule is the (packed) address of an I6 routine. In the case of rules created in I7 source text, the body of the rule definition is compiled by NI to a new I6 routine which carries it out. But there are also primitive rules which are implemented in the template I6 layer, and these need no I7 source text definitions: instead we simply tell NI the name of the I6 routine which will be handling this rule, and that it need not bother to create one for itself.

An example of this is provided by the first rule we shall create: the "little-used do nothing rule". This is aptly named on both counts. We never follow it, we never put it into any rulebook. It exists only so that variables and properties with the kind of value "rule" can be initialised automatically to a safely neutral default value. It makes no decision.

```
Section SR2/8 - The Standard Rules

The little-used do nothing rule translates into I6 as "LITTLE_USED_DO_NOTHING_R".

Include (-
[ LITTLE_USED_DO_NOTHING_R; rfalse; ];
-);
```

§**23. Startup.** The startup rulebook is considered but not followed (see above) and so is immunised from the effect of procedural rules.

Every rulebook contains a (possibly empty) run of "first" rules, then a (possibly empty) run of miscellaneous rules, then a (possibly empty) run of "last" rules. It's unusual to have more than one rule anchored to either end as "first" or "last", but entirely legal, and we make use of that ability here.

The "first" rules here are the ones which get the basic machinery working to the point where it is safe to run arbitrary I7 source text. They necessarily do very low-level things, and it is not guaranteed that I7 phrases will behave to specification if executed before these early rules have finished. So it is hazardous to obstruct or alter them.

(a) The "virtual machine startup rule" carries out necessary steps to begin execution on the virtual machine in use: this entails relatively little on the Z-machine versions 5 or 8, but can involve extensive work to get the screen display working on Glulx or Z6. Before anything else happens, however, the "starting the virtual machine" activity (see below) is carried out: again, this is done in a careful way which avoids procedural rules firing.

(b) The "initialise memory rule" starts up the memory allocation heap, if there is one, and sets some essential I6 variables. If there is any rule not to meddle with, this is it.

(c) The "seed random number generator rule" seeds the RNG to a fixed value if NI has requested this (which it does in response to the `-rng` command line switch, which is in turn used by the `intest` testing utility: it's a way to make deterministic tests of programs which use random values).

(d) The "update chronological records rule" is described in further detail below, since it appears both here and also in the turn sequence rulebook. Here it's providing us with a baseline of initial truths from which we can later assess conditions such as "the marble door has been open". A subtle and questionable point of the design is that this rule is placed at a time when the object representing the player is not present in the model world. This is done to avoid regarding the initial situation as one of the turns for purposes of a rule preamble like "... when the player has been in the Dining Room for three turns". It's as if the player teleports into an already-existing world, like some Star Trek crewman, just in time for the first command.

(e) And the "position player in model world rule" completes the initial construction of the spatial model world.

(f) The "start in the correct scenes rule" ensures that we start out in the correct scenes. (This can't wait, because it's just conceivable that somebody has written a rule with a preamble like "When play begins during the Hunting Season...": it's also where the scene Entire Game begins.) That completes the necessary preliminaries before ordinary I7 rules can be run.

```
The start in the correct scenes rule is listed first in the startup rulebook. [6th.]
The position player in model world rule is listed first in the startup rulebook. [5th.]
The update chronological records rule is listed first in the startup rulebook. [4th.]
The seed random number generator rule is listed first in the startup rulebook. [3rd.]
The initialise memory rule is listed first in the startup rulebook. [2nd.]
The virtual machine startup rule is listed first in the startup rulebook. [1st.]

The virtual machine startup rule translates into I6 as "VIRTUAL_MACHINE_STARTUP_R".
The initialise memory rule translates into I6 as "INITIALISE_MEMORY_R".
The seed random number generator rule translates into I6 as "SEED_RANDOM_NUMBER_GENERATOR_R".
The update chronological records rule translates into I6 as "UPDATE_CHRONOLOGICAL_RECORDS_R".
The position player in model world rule translates into I6 as "POSITION_PLAYER_IN_MODEL_R".

This is the start in the correct scenes rule: consider the scene changing rules.
```

§**24.** The remaining rules, though, are fair game for alteration, and as if to prove the point they are all written in standard I7 source text. Note that the baseline score is set only after the when play begins rulebook has finished, because games starting with a non-zero score normally do this by changing the score in a when play begins rule: and we don't want such a change to be notified to the player as if it has happened through some action.

```
The when play begins stage rule is listed in the startup rulebook.
The fix baseline scoring rule is listed in the startup rulebook.
The display banner rule is listed in the startup rulebook.
The initial room description rule is listed in the startup rulebook.

This is the when play begins stage rule: follow the when play begins rulebook.

This is the fix baseline scoring rule: now the last notified score is the score.

This is the display banner rule: say "[banner text]".

This is the initial room description rule: try looking.
```

§**25. The turn sequence.** In each turn, a command is read and parsed from the keyboard, and any action(s) that requested is or are processed. (And may in turn cause other actions, which must also be processed.) There is then a fair amount of business needed to end one turn and get ready for another.

The turn sequences rulebook terminates early if `deadflag` becomes set at any point, so the last turn of play will be incomplete. Besides that consideration, it can also end early if the command for the turn was for an out-of-world action such as saving the game: in such cases, the "generate action rule" stops the rulebook once the action has been fully processed. All the same, play basically consists of running down this list of rules over and over again.

The turn sequence rulebook is the only one protected from being ignored by a procedural rule: ignoring it would lock the story file into an endless loop, so a run-time problem is issued instead if this is tried. (In pre-2008 drafts of Inform 7, ignoring what was then the turn sequence rulebook was a legitimate tactic, so the RTP message explains how to achieve the same effect by new methods.)

§**26.** The "first" rules in the turn sequence cover us up to the end of the events which take place in the model world during this turn's action(s).

(a) The "parse command rule" prints up the prompt, reads a command from the keyboard, parses it into dictionary words, deals with niceties such as UNDO or OOPS, and then runs it through the traditional I6 parser to turn it into a request for an action or list of actions. But see note below.

(b) The "generate action rule" then either sends a single action to the action-processing rules, or else runs through the list, printing the noun up with a colon each time and then sending the action to the action-processing rules. But see note below.

(c) We then run the scene changing rulebook, because people often write every turn rules which are predicated on particular scenes ("Every turn during the Grand Waltz: ..."), and such rules will fail if we haven't kept up with possible scene changes arising from something done in the action(s) just completed.

(d) The "every turn stage rule" follows the every turn rulebook. This earns its place among the "first" rules in order for it to have priority over all the other book-keeping rules at the end of a turn – including any which the user, or an extension included by the user, chooses to add to the turn sequence rules.

An unusual point here is that the "parse command rule" and the "generate action rule" are written such that they *do nothing unless the turn sequence rulebook is being followed at the top level* (by `Main`, that is). This prevents them from being used recursively, which would not work properly, and enables a popular trick from the time before the 2008 reform to keep working: we can simulate six turns going by in which the player does nothing by running "follow the turn sequence rules" six times in a row. Everything happens exactly as it should – the turn count, the time of day, timed events, and so on – except that no commands are read and no consequent actions generated.

```
A first turn sequence rule (this is the every turn stage rule): follow the every turn rules. [4th.]
A first turn sequence rule: consider the scene changing rules. [3rd.]
The generate action rule is listed first in the turn sequence rulebook. [2nd.]
The parse command rule is listed first in the turn sequence rulebook. [1st.]
```

§**27.** Three miscellaneous things then happen, all implemented by primitives in the template I6 layer:

(e) The "timed events rule" is the one which causes other rules, keyed to particular times of day, to fire.

(f) The "advance time rule" then causes the "time of day" global variable to advance by the duration of a single turn, which by default is 1 minute.

(g) The "update chronological records rule" tells the chronology machine that a slice of time has been completed. Inform can only decide past tense conditions like "the black door has been open" by continuously measuring the present to see if the black door is open now, and making a note for future reference if it is. But of course it's impossible for any computer to continuously do anything, and besides, Inform has other calls on it. What in fact happens is the Inform performs these measurements at "chronology points", which are strategic moments during play, and this is one of them.

```
The timed events rule is listed in the turn sequence rulebook.
The advance time rule is listed in the turn sequence rulebook.
The update chronological records rule is listed in the turn sequence rulebook.
```

§**28.** We now come to the rules anchored at the end, using "last". This part of the rulebook is reserved for book-keeping which has to happen positively at the end of the turn.

(h) First, we check for scene changes again. We did this only a short while ago, but scene changes might well have arisen as a result of rules which fired during the every turn rulebook, or from timed events, or in some other way, and it's important to start the next turn in the correct scene – so we check again to make sure.

(i) Then we run the "adjust light rule". Keeping track of light and darkness is quite difficult, and potentially also quite slow: it's not unlike a sort of discretised version of ray-tracing, with many light sources and barriers to think about (some transparent, some opaque). So we do this as little as possible: once per turn we calculate whether the player is in light or not, and act accordingly if so.

(j) The "note object acquisitions rule" does two things:

  (i) Gives the "handled" property to everything carried or worn by the player.

  (ii) Changes the current player's holdall in use, if necessary. (That's to say: if the player has dropped his previous player's holdall, we try to find a new one to use from his remaining possessions.)

(k) The "notify score changes rule" tells the player if the score has changed during the turn, or rather, since the last time either this rule or the startup "fix baseline scoring rule" ran. (If the score were to change in the course of an out-of-world action, it would be notified a turn late, but of course out-of-world actions are not supposed to do that sort of thing.)

```
A last turn sequence rule: consider the scene changing rules. [3rd from last.]
The adjust light rule is listed last in the turn sequence rulebook. [2nd from last.]
The note object acquisitions rule is listed last in the turn sequence rulebook. [Penultimate.]
The notify score changes rule is listed last in the turn sequence rulebook. [Last.]

This is the notify score changes rule:
    if the score is not the last notified score:
        issue score notification message;
        now the last notified score is the score;
```

§**29.** That's it, but we need to map these I7 rule names onto the names of their I6 primitives in the template layer.

```
The adjust light rule translates into I6 as "ADJUST_LIGHT_R".
The advance time rule translates into I6 as "ADVANCE_TIME_R".
The generate action rule translates into I6 as "GENERATE_ACTION_R".
The note object acquisitions rule translates into I6 as "NOTE_OBJECT_ACQUISITIONS_R".
The parse command rule translates into I6 as "PARSE_COMMAND_R".
The timed events rule translates into I6 as "TIMED_EVENTS_R".
```

§**30. Shutdown.** Goodbye is not the hardest word to say, but it does involve a little bit of work. It might not actually be goodbye, for one thing: if this rulebook ends in success, then we go back to repeating the turn sequence rulebook just as if nothing had happened.

(a) The "when play ends stage rule" follows the rulebook of the same name.

(b) The "resurrect player if asked rule" does nothing unless one of the "when play ends" rules ran the "resume the game" phrase, in which case it stops the rulebook with success (see above).

(c) The "print player's obituary rule" carries out the activity of nearly the same name (see below).

(d) The "ask the final question rule" asks the celebrated "Would you like to RESTART, RESTORE a saved game or QUIT?" question, and acts on the consequences. It can also cause an UNDO, and on a victorious ending may carry out the "amusing a victorious player" activity (see below). The rule only actually ends in the event of a QUIT: an UNDO, RESTART or RESTORE is performed at the hardware level by the virtual machine and destroys the current execution context entirely.

```
The when play ends stage rule is listed first in the shutdown rulebook.
The resurrect player if asked rule is listed last in the shutdown rulebook.
The print player's obituary rule is listed last in the shutdown rulebook.
The ask the final question rule is listed last in the shutdown rulebook.

This is the when play ends stage rule: follow the when play ends rulebook.
This is the print player's obituary rule:
    carry out the printing the player's obituary activity.

The resurrect player if asked rule translates into I6 as "RESURRECT_PLAYER_IF_ASKED_R".
The ask the final question rule translates into I6 as "ASK_FINAL_QUESTION_R".
```

§**31. Scene changing.** Scene changing is handled by a routine called `DetectSceneChange` which is compiled directly by NI: this is so primitive that it can't even be handled at the template layer. The rulebook is all a little elaborate given that it contains only one rule, but it's possible to imagine extensions which need to do book-keeping similar to scene changing and which want to make use of this opportunity.

```
The scene change machinery rule is listed last in the scene changing rulebook.

The scene change machinery rule translates into I6 as "DetectSceneChange".
```

§**32.** We couldn't do this earlier (because creating a scene automatically generates two rulebooks, and that would have thrown the rulebook numbering), so let's take this opportunity to define the "Entire Game" scene:

```
Section SR2/9 - The Entire Game scene

The Entire Game is a scene.
The Entire Game begins when the game is in progress.
The Entire Game ends when the game is over.
```

§**33. Action-processing.** Action-processing happens on two levels: an upper level, handled by the main "action-processing" rulebook, and a lower level, "specific action-processing". This division clearly complicates matters, so why do we do it? It turns out be convenient for several reasons:

(a) Out-of-world actions like "saving the game" need to run through the lower level, or they won't do anything at all, but must not run through the upper level, or in-world rules (before or instead rules, for instance) might prevent them from happening.

(b) Requested actions such as generated by a command like "CLARK, BLOW WHISTLE" have the reverse behaviour, being handled at the upper level but not the lower. (If Clark should agree, a definite non-request action "Clark blowing the whistle" is generated afresh: that one does indeed get to the lower level, but the original request action doesn't.)

(c) Specific action-processing has a rather complicated range of outcomes: it must succeed or fail, according to whether the action either reaches the carry out rules or is converted into another action which does, but also ensure that in the event of failure, the exact rule causing the failure is recorded in the "reason the action failed" variable.

(d) The specific action-processing stage is where we have to split consideration into action-specific rulebooks (like "check taking") rather than general ones (like "instead"). To get this right, we want to use some rulebook variables, and these need to be set at exactly the correct moment. It's tricky to arrange for that in the middle of a big rulebook, but easy to do so at the beginning, so we want the start of the SA-P stage to happen at the start of a rulebook.

This does mean that an attempt by the user to move the before stage to just after the check stage (say) will fail – the before and check stages happen in different rulebooks, so no amount of rearranging will do this. (Procedural rules could still achieve this very doubtfully wise effect in any case.)

§**34.** The upper level of action-processing consists of seeing whether the actor's current situation forbids the action from being tried: does anybody or anything intervene to stop it? Are there are any basic reasons of physical realism why nobody could possibly try it? Does it require somebody else to cooperate who in fact chooses not to?

Doctrinally, the before stage must see actions before anything else can happen. (It needs the absolute freedom to start fresh actions and dispose of the one originally intended, sure in the knowledge that no other rules have been there first.) So before-ish material is anchored at the "first" end of the rulebook.

The other book-end on the shelf is provided by the instead stage, which doctrinally happens only when the action is now thought to be physically reasonable. So this is anchored at the "last" end. (In fact it is followed by several more rules also anchored there, but this is essentially just the clockwork machinery showing through: they aren't realism checks.)

Miscellaneous general rules to do with physical realism are placed between the two book-ends, then, and this is where any newly created action-processing rules created by the user or by extensions will go.

```
Section SR2/10 - Action processing

The before stage rule is listed first in the action-processing rules. [3rd.]
The set pronouns from items from multiple object lists rule is listed first in the
    action-processing rules. [2nd.]
The announce items from multiple object lists rule is listed first in the
    action-processing rules. [1st.]
The basic visibility rule is listed in the action-processing rules.
The basic accessibility rule is listed in the action-processing rules.
The carrying requirements rule is listed in the action-processing rules.
The instead stage rule is listed last in the action-processing rules. [4th from last.]
The requested actions require persuasion rule is listed last in the action-processing rules.
The carry out requested actions rule is listed last in the action-processing rules.
The descend to specific action-processing rule is listed last in the action-processing rules.
The end action-processing in success rule is listed last in the action-processing rules. [Last.]
```

§**35.** As we shall see, most of these rules are primitives implemented by the template I6 layer, but five are very straightforward.

```
This is the set pronouns from items from multiple object lists rule:
    if the current item from the multiple object list is not nothing,
        set pronouns from the current item from the multiple object list.
This is the announce items from multiple object lists rule:
    if the current item from the multiple object list is not nothing,
        say "[current item from the multiple object list]: [run paragraph on]".
This is the before stage rule: abide by the before rules.
This is the instead stage rule: abide by the instead rules.
```

§**36.** The final rule in the rulebook always succeeds: this ensures that action-processing always makes a decision. (I7's doctrine is that an action "succeeds" if and only if its carry-out stage is reached, so any action getting right to the end of this rulebook must have succeeded.)

```
This is the end action-processing in success rule: rule succeeds.
```

§**37.** The action-processing rulebook contains six primitives:

(1) The "basic visibility rule" checks the action to see if it requires light, and if so, and if the actor is the player and in darkness, asks the visibility rules (see below) whether the lack of light should stop the action. (It would be cleaner to apply this rule to all actors, but we would need much more extensive light calculations to do this.)

(2) The "basic accessibility rule" checks the action to see if it requires the noun to be touchable, and if so, asks the accessibility rulebook to adjudicate (see below); then repeats the process for the second noun.

(3) The "carrying requirements rule" checks the action to see if it requires the noun to be carried. If so, but the noun is not carried, it generates an implicit taking action (in effect, "try silently taking N"); and if that fails, then the rulebook is halted in failure. The process is then repeated for the second noun.

(4) If the action is one where the player requests somebody else to do something, the "requested actions require persuasion rule" asks the persuasion rulebook for permission.

(5) If the action is one where the player requests somebody else to do something, the "carry out requested actions rule" starts a new action by the person asked, and looks at the result: if it failed, the "unsuccessful attempt by" rulebook is run to tell the player what has (not) happened. (If that does nothing, a bland message is printed.) In all cases, the original action of requesting is ended in success: a success because, whatever happened, the request succeeded in making the actor try to do something.

(6) The "descend to specific action-processing rule" really only runs the specific action-processing rulebook, but it's implemented as a primitive in the template I6 layer because it must also find out which are the specific check, carry out and report rulebooks for the current action (for instance, "check taking" is the specific check rulebook for the "taking" action – which seems obvious from the names: but at run-time, the names aren't so visible).

```
The basic accessibility rule translates into I6 as "BASIC_ACCESSIBILITY_R".
The basic visibility rule translates into I6 as "BASIC_VISIBILITY_R".
The carrying requirements rule translates into I6 as "CARRYING_REQUIREMENTS_R".
The requested actions require persuasion rule translates into I6 as "REQUESTED_ACTIONS_REQUIRE_R".
The carry out requested actions rule translates into I6 as "CARRY_OUT_REQUESTED_ACTIONS_R".
The descend to specific action-processing rule translates into I6 as
"DESCEND_TO_SPECIFIC_ACTION_R".
```

§**38. Specific action-processing.** And now we descend to the lower level, which is much easier to understand.

```
The work out details of specific action rule is listed first in the specific
action-processing rules.

A specific action-processing rule
    (this is the investigate player's awareness before action rule):
    consider the player's action awareness rules;
    if rule succeeded, change within the player's sight to true;
    otherwise change within the player's sight to false.

A specific action-processing rule (this is the check stage rule):
    anonymously abide by the specific check rulebook.

A specific action-processing rule (this is the carry out stage rule):
    consider the specific carry out rulebook.

A specific action-processing rule (this is the after stage rule):
    if action in world is true, abide by the after rules.

A specific action-processing rule
    (this is the investigate player's awareness after action rule):
    if within the player's sight is false:
        consider the player's action awareness rules;
        if rule succeeded, change within the player's sight to true;

A specific action-processing rule (this is the report stage rule):
    if within the player's sight is true and action keeping silent is false,
        consider the specific report rulebook;

The last specific action-processing rule: rule succeeds.
```

§**39.** The unusual use of "anonymously abide by" above is a form of "abide by" which may be worth explaining. Suppose rule X consists of an instruction to abide by rulebook Y, and suppose that Y in fact fails when it reaches Y_k. If the ordinary "abide by" is used then the action will be deemed to have failed at rule X, but if "anonymously abide by" is used then it will be deemed to have failed at Y_k. (Thus X remains anonymous: it can never be the culprit.) We only use this at the check stage, because the carry out, report and after stages are not allowed to fail the action. (The after stage is allowed to end it, but not in failure.)

§**40.** The specific action-processing rulebook is probably more fruitful than the main one if we want to modify what happens. For instance:

```
This is the sixth sense rule: if the player is not the actor, say "You sense that [the actor] is up to
something."

The sixth sense rule is listed before the carry out stage rule in the specific action-processing rules.
```

...produces the message at a time when the action is definitely possible and will succeed, but before anything has been done.

§**41.** The only rule not spelled out was the primitive "work out details of specific action rule", which initialises the rulebook variables so that they record the action's specific check, carry out and report rulebooks, and whether or not it is in world.

```
The work out details of specific action rule translates into I6 as
"WORK_OUT_DETAILS_OF_SPECIFIC_R".
```

§**42. Player's action awareness.** This rulebook decides whether or not an action by somebody should be routinely reported to the player: is he aware of it having taken place? If the rulebook positively succeeds then he is, and otherwise not.

```
A player's action awareness rule
    (this is the player aware of his own actions rule):
    if the player is the actor, rule succeeds.
A player's action awareness rule
    (this is the player aware of actions by visible actors rule):
    if the player is not the actor and the player can see the actor, rule succeeds.
A player's action awareness rule
    (this is the player aware of actions on visible nouns rule):
    if the noun is a thing and the player can see the noun, rule succeeds.
A player's action awareness rule
    (this is the player aware of actions on visible second nouns rule):
    if the second noun is a thing and the player can see the second noun, rule succeeds.
```

§**43. Accessibility.** The "accessibility" rulebook is not very visible to users: it's another behind-the-scenes rulebook for managing the decision as to whether the actor can touch any items which the intended action requires him to be able to reach.

In its default configuration, it contains only the "access through barriers" rule. This in all circumstances either succeeds or fails: in other words, it makes a definite decision, and this is why it is anchored as "last" in the rulebook. If users or extensions want to tweak accessibility at this general level, any new rules they add will get the chance to decide before the "access through barriers" rule settles the matter. But in practice we expect most users to work with one of the two reaching rulebooks instead.

```
Section SR2/11 - Accessibility

The access through barriers rule is listed last in the accessibility rules.

The access through barriers rule translates into I6 as "ACCESS_THROUGH_BARRIERS_R".
```

§**44. Reaching inside.** What the access through barriers rule does is to try to construct a path through the object containment tree from the actor to the item needed, and to apply the reaching inside or reaching outside rulebooks each time this path passes inside or outside of a container (or room). (Supporters never form barriers.)

```
The can't reach inside rooms rule is listed last in the reaching inside rules. [Penultimate.]
The can't reach inside closed containers rule is listed last in the reaching
inside rules. [Last.]

The can't reach inside closed containers rule translates into I6 as "CANT_REACH_INSIDE_CLOSED_R".
The can't reach inside rooms rule translates into I6 as "CANT_REACH_INSIDE_ROOMS_R".
```

§**45. Reaching outside.** And, not quite symmetrically since we don't need to block room-to-room reaching on both the inbound and outbound directions,

```
The can't reach outside closed containers rule is listed last in the reaching outside rules.

The can't reach outside closed containers rule translates into I6 as "CANT_REACH_OUTSIDE_CLOSED_R".
```

§**46. Visibility.** The visibility rulebook actually has the opposite sense to the one the name might suggest. It is applied only when the player (not any other actor) tries to perform an action which requires light to see by; the action is blocked if the rulebook succeeds. (Well, but we could hardly call it the invisibility rulebook. The name is supposed to suggest that the consideration of visibility is being applied: rather the way cricket matches end with a declaration that "light stopped play", meaning of course that darkness did.)

```
The can't act in the dark rule is listed last in the visibility rules.
The last visibility rule (this is the can't act in the dark rule): if in darkness, rule succeeds.
```

§**47. Does the player mean.** This rulebook is akin to a set of preferences about how to interpret the player's commands in cases of ambiguity. No two Inform users are likely to agree about the best way to decide these, so we are fairly hands-off, and make only one rule as standard:

```
Does the player mean taking something which is carried by the player
    (this is the very unlikely to mean taking what's already carried rule):
    it is very unlikely.
```

§**48.** And that completes the creation and stocking of the 25 rulebooks. More than half of them are initially empty, including before, instead and after – at the end of the day, these rulebooks are hooks allowing the user to change the ordinary behaviour of things, but ordinariness is exactly what the Standard Rules is all about.

§**49. Adjectives applied to values.** There is a small stock of built-in adjectives for values.

```
Definition: a number is even rather than odd if the remainder after dividing it by 2 is 0.
Definition: a number is positive if it is greater than zero.
Definition: a number is negative if it is less than zero.
Definition: a text is empty rather than non-empty if it is "".
Definition: an indexed text is empty rather than non-empty if I6 routine
    "INDEXED_TEXT_TY_Empty" says so (it contains no characters).
A scene can be recurring or non-recurring. A scene is usually non-recurring.
Definition: a scene is happening if I6 condition "scene_status-->(*1-1)==1"
    says so (it is currently taking place).
Definition: a table-name is empty rather than non-empty if the number of filled rows in it is 0.
Definition: a table-name is full rather than non-full if the number of blank rows in it is 0.
Definition: a rulebook is empty rather than non-empty if I6 routine "RulebookEmpty" says so (it
    contains no rules, so that following it does nothing and makes no decision).
Definition: an activity is empty rather than non-empty if I6 routine "ActivityEmpty" says so (its
    before, for and after rulebooks are all empty).
Definition: an activity is going on if I6 routine "TestActivity" says so (one
    of its three rulebooks is currently being run).
Definition: a list of values is empty rather than non-empty if I6 routine
    "LIST_OF_TY_Empty" says so (it contains no entries).
```

SR3 - Activities A/sr3

Purpose

The built-in activities and their default stock of rules; the locale description mechanism.

A/sr3.§20 Locale activities; §21 Locale Implementation; §22 Printing the Locale Description; §23 Choosing Notable Locale Objects; §24 Printing a Locale Paragraph

---

§**1.** These must not be created until the basic rulebooks are in place, because creating any activity automatically creates three rulebooks as well.

Once again, there are no activities or assumptions about them built into NI, but the template I6 layer expects the following 26 activities to be created and in this order. (That is, the order here must exactly match that of the `*_ACT` constant definitions made in `Definitions.i6t`.) The activities are fairly completely described in the Inform documentation, so the only notes here concern implementation.

§**2.** We start with activities used in describing things and rooms.

Most of the activities begin with all three rulebooks empty, since by default they do not intervene. This one, however, has a "last" for-rule, because it's required to do something definite: it must actually print a name, and the last for-rule is the default way to do this. (The assumption is that any other for-rule added by the user will halt the rulebook before the default implementation is reached.) We also include a before rule which marks any item whose name is being printed with the "mentioned" property, for reasons to be found below.

```
Part SR3 - Activities

Printing the name of something (documented at act_pn) is an activity. [0]

Before printing the name of a thing (called the item being printed)
    (this is the make named things mentioned rule):
    now the item being printed is mentioned.

The standard name printing rule is listed last in the for printing the name rulebook.
The standard name printing rule translates into I6 as "STANDARD_NAME_PRINTING_R".

Printing the plural name of something (documented at act_ppn) is an activity. [1]

Rule for printing the plural name of something (called the item) (this is the standard
    printing the plural name rule):
    say the printed plural name of the item.
The standard printing the plural name rule is listed last in the for printing
the plural name rulebook.

Printing a number of something (documented at act_pan) is an activity. [2]

Rule for printing a number of something (called the item) (this is the standard
    printing a number of something rule):
    say "[listing group size in words] ";
    carry out the printing the plural name activity with the item.
The standard printing a number of something rule is listed last in the for printing
a number rulebook.
```

§**3.** When they occur in room descriptions, names of things are sometimes supplemented by details:

```
Printing room description details of something (documented at act_details) is an activity. [3]
```

§**4.** Names of things are often formed up into lists, in which they are sometimes grouped together:

```
Listing contents of something (documented at act_lc) is an activity. [4]
The standard contents listing rule is listed last in the for listing contents rulebook.
The standard contents listing rule translates into I6 as "STANDARD_CONTENTS_LISTING_R".
Grouping together something (documented at act_gt) is an activity. [5]
```

§**5.** And such lists of names are formed up in turn into room descriptions. Something which is visible in a room can either have a paragraph of its own or can be relegated to the list of "nondescript" items at the end.

```
Writing a paragraph about something (documented at act_wpa) is an activity. [6]
```

§**6.** When these paragraphs have all gone by, the nondescript items left over are more briefly listed: the following activity gets the chance to change how this is done.

```
Listing nondescript items of something (documented at act_lni) is an activity. [7]
```

§**7.** Darkness behaves, for room description purposes, a little as if it were a room in its own right. Until the 1990s that was almost always how darkness was implemented in IF programs: this persists in I6, but not I7, where the existence of a room-which-is-not-a-room would break type safety.

```
Printing the name of a dark room (documented at act_darkname) is an activity. [8]
Printing the description of a dark room (documented at act_darkdesc) is an activity. [9]
Printing the announcement of darkness (documented at act_nowdark) is an activity. [10]
Printing the announcement of light (documented at act_nowlight) is an activity. [11]
Printing a refusal to act in the dark (documented at act_toodark) is an activity. [12]

The look around once light available rule is listed last in for printing the
announcement of light.

This is the look around once light available rule:
    try looking.
```

§**8.** Two special forms of printing: the status line at the top of the screen, refreshed every turn during play, and the banner which appears at or close to the start of play:

```
Constructing the status line (documented at act_csl) is an activity. [13]
Printing the banner text (documented at act_banner) is an activity. [14]
```

§**9.** Now a brace of activities to intervene in how the Inform parser does its parsing, arranged roughly in chronological order of their typical use during a single turn of a typed command, its parsing, and final conversion into an action.

The unusual notation "(future action)" here allows NI to parse rule preambles for these activities in a way which would refer to the action which might, at some point in the future, be generated – during parsing we don't of course yet know what that action is, but there is always a current guess at what it might be.

```
Reading a command (documented at act_reading) is an activity. [15]
Deciding the scope of something (future action) (documented at act_ds) is an activity. [16]
Deciding the concealed possessions of something (documented at act_con) is an activity. [17]
Deciding whether all includes something (future action) (documented at act_all)
    is an activity. [18]
The for deciding whether all includes rules have outcomes it does not (failure) and
    it does (success).
Clarifying the parser's choice of something (future action) (documented at act_clarify)
    is an activity. [19]
Asking which do you mean (future action) (documented at act_which) is an activity. [20]
Printing a parser error (documented at act_parsererror) is an activity. [21]
Supplying a missing noun (documented at act_smn) is an activity. [22]
Supplying a missing second noun (documented at act_smn) is an activity. [23]
Implicitly taking something (documented at act_implicitly) is an activity. [24]
```

§**10.** The supplying activities are linguistically interesting, for reasons gone into in the paper *Interactive Fiction, Natural Language and Semantic Analysis*: English verbs do not naturally seem to feature optional nouns. Indeed, we say "it rained on Tuesday" where "it" refers to nothing at all, merely because we can't bring ourselves to leave a gap and say just "rained on Tuesday". A better example here would be "it sounded like rain", because we do the same to convey the idea of listening ambiently rather than to any single thing: listening appears to be rare among actions in that it can equally well take a noun as not. Just as English handles this problem by supplying a spurious "it" which appears to mean "the world at large", so Inform handles it by supplying the current location, with the same idea in mind. And the same applies to the sense of smell, which can be similarly defocused.

```
Rule for supplying a missing noun while an actor smelling (this is the ambient odour rule):
    change the noun to the location.
Rule for supplying a missing noun while an actor listening (this is the ambient sound rule):
    change the noun to the location.
```

§**11.** The following rule is something of a dodge to provide a better parser response to commands like GO or BRETT, GO. (Putting the rule here, and giving it a name, allows the user to override it and thus accept the idea of vague going after all.)

```
Rule for supplying a missing noun while an actor going (this is the block vaguely going rule):
    issue library message going action number 7.
```

§**12.** The very first rules: those invoked at the earliest possible moment when the virtual machine is starting up. We need this hook, really, for the Glulx VM, which requires various styles to be created.

```
Starting the virtual machine (documented at act_startvm) is an activity. [25]
The enable Glulx acceleration rule is listed first in for starting the virtual machine.
The enable Glulx acceleration rule translates into I6 as "ENABLE_GLULX_ACCEL_R".
```

§**13.** And the very last rules of all. The obituary is a rare example of a sequence of events in the I6 library having been rolled up into an activity, partly because it's one of the few clear-cut moments where several unconnected things happen in succession.

```
Amusing a victorious player (documented at act_amuse) is an activity. [26]

Printing the player's obituary (documented at act_obit) is an activity. [27]
The print obituary headline rule is listed last in for printing the player's obituary.
The print final score rule is listed last in for printing the player's obituary.
The display final status line rule is listed last in for printing the player's obituary.

The print obituary headline rule translates into I6 as "PRINT_OBITUARY_HEADLINE_R".
The print final score rule translates into I6 as "PRINT_FINAL_SCORE_R".
The display final status line rule translates into I6 as "DISPLAY_FINAL_STATUS_LINE_R".
```

§**14.** There is one last question: the one which usually reads "Would you like to RESTART, RESTORE a saved game, or QUIT?", but which sometimes provides other options too. The "ask the final question rule" handles this, and does so by repeatedly calling the following activity:

```
Handling the final question is an activity. [28]
```

§**15.** It follows that this activity *must* at least sometimes do something dramatic to the execution state: perform a quit, for instance. Four primitive rules are available for the drastic things which the activity might wish to do, but these are not placed in any rulebook: instead they are available for anyone who wants to call them. (In the default implementation below, we put references to them into a table.)

```
The immediately restart the VM rule translates into I6 as "IMMEDIATELY_RESTART_VM_R".
The immediately restore saved game rule translates into I6 as "IMMEDIATELY_RESTORE_SAVED_R".
The immediately quit rule translates into I6 as "IMMEDIATELY_QUIT_R".
The immediately undo rule translates into I6 as "IMMEDIATELY_UNDO_R".
```

§**16.** We structure the activity so that the printing of the question and typing of the answer take place at the "before" stage, and then the parsing and acting upon this answer take place at the "for" stage. Reading the keyboard is the last rule in "before". With the "for" stage, the idea is that any extra rule slipped in by the user can take precedence over the default implementation, so the latter is the last there, too.

```
The print the final question rule is listed in before handling the final question.
The print the final prompt rule is listed in before handling the final question.
The read the final answer rule is listed last in before handling the final question.
The standard respond to final question rule is listed last in for handling the final question.

This is the print the final prompt rule: say "> [run paragraph on]".

The read the final answer rule translates into I6 as "READ_FINAL_ANSWER_R".
```

§**17.** That clears away the underbrush and reduces us to two matching tasks: (i) to print the question, (ii) to parse the answer, given that we want to be able to vary the set of choices available.

We do this by reading the options from the Table of Final Question Options. (See below for its default contents.) Each row is an option, whose wording must be placed in the topic column. The final question wording entry can either be text describing the option – e.g., "perform a RESTART" – or can be left blank, making the option a secret one, omitted from the question but still recognised as an answer. The only if victorious entry can be set to make the option available only after a victorious ending, not after a loss; Infocom's traditional AMUSING option behaved thus. Finally, the table specifies what to do if the option is taken: either it provides a rule, or an activity to carry out. (If it provides only an activity, but that activity is empty, then the option is omitted from the question and not recognised as an answer.)

```
This is the print the final question rule:
    let named options count be 0;
    repeat through the Table of Final Question Options:
        if the only if victorious entry is false or the game ended in victory:
            if there is a final response rule entry
                or the final response activity entry [activity] is not empty:
                if there is a final question wording entry, increase named options count by 1;
    if the named options count is less than 1, abide by the immediately quit rule;
    say "Would you like to ";
    repeat through the Table of Final Question Options:
        if the only if victorious entry is false or the game ended in victory:
            if there is a final response rule entry
                or the final response activity entry [activity] is not empty:
                if there is a final question wording entry:
                    say final question wording entry;
                    decrease named options count by 1;
                    if the named options count is 0:
                        say "?[line break]";
                    otherwise if the named options count is 1:
                        if using the serial comma option, say ",";
                        say " or ";
                    otherwise:
                        say ", ";
```

§**18.** And the matching rule to parse and respond to the answer:

```
This is the standard respond to final question rule:
    repeat through the Table of Final Question Options:
        if the only if victorious entry is false or the game ended in victory:
            if there is a final response rule entry
                or the final response activity entry [activity] is not empty:
                if the player's command matches the topic entry:
                    if there is a final response rule entry, abide by final response rule entry;
                    otherwise carry out the final response activity entry activity;
                    rule succeeds;
    issue miscellaneous library message number 8.
```

§**19.** The table of final options is the only material under the heading "Section SR/Q", to make it easy for users to replace with entirely different tables.

These settings are the traditional ones used by Inform since 1995 or so. The UNDO option has customarily been a "secret", though not much of one, since it somewhat cheapens the announcement of a calamity to be immediately offered the chance to reverse it: death, where is thy sting?

```
Section SR2/12 - Final question options

Table of Final Question Options
final question wording only if victorious topic final response rule final response activity
"RESTART" false "restart" immediately restart the VM rule --
"RESTORE a saved game" false "restore" immediately restore saved game rule --
"see some suggestions for AMUSING things to do" true "amusing" -- amusing a victorious player
"QUIT" false "quit" immediately quit rule --
-- false "undo" immediately undo rule --
```

§**20. Locale activities.** A "locale description" is a segment of the text produced by LOOK: the "locale" is a clutch of objects at a given level in the object tree. Most room descriptions consist of a top line, a description of the place, and then a single (though often, as here, multi-paragraph) locale:

```
Sentier Le Corbusier
A coastal walk along the rocky shore between Nice and Menton.
```
now the locale for the room Sentier Le Corbusier:
```
A translucent jellyfish has been washed up by the waves.

You can also see a bucket and a spade here.
```

A locale typically contains a run of paragraphs specific to interesting items, especially those not yet picked up, followed by a paragraph which lists the "nondescript" items – those not given paragraphs of their own, such as the bucket and spade. (Some items, though – typically scenery, but also for instance the player – are not even nondescript and do not appear at all.) A locale can contain no interesting paragraphs, or no list of nondescript items, or can even contain neither: that is, it can be entirely empty.

When the player is in or on top of something, multiple locales are described:

```
Sentier Le Corbusier (in the golf cart)
A coastal walk along the rocky shore between Nice and Menton.
```
now the locale for the room Sentier Le Corbusier:
```
A translucent jellyfish has been washed up by the waves.

You can also see a bucket and a spade here.
```
now the locale for the golf cart:
```
In the golf cart you can see a map of Villefranche-sur-Mer.
```

To sum up, the text produced by LOOK consists of a header (produced by the carry out looking rules) followed by one or more locale descriptions (produced by the activity below).

§**21. Locale Implementation.** When describing a locale, we keep a Table of interesting objects, each associated with a priority – a number indicating how important, and therefore how near to the top of the description, the object is. A special syntax allows us to create the Table with exactly the same number of rows as there are things in the model world: thus, in the worst case where all things are in a single locale, we still will not run out of table rows. (We do this rather than creating a large but fixed-size table because memory is very short in some Z-machine I7 works, so we want to take only what we might actually need. The table structure is not as wasteful as it might look: an experiment with using a number property of things instead showed that this table was actually more efficient, because of the property numbering overhead in the Z-machine memory representation of objects.)

```
Section SR2/13 - Locale descriptions - Unindexed

Table of Locale Priorities
notable-object (an object) locale description priority (a number)
-- --
with blank rows for each thing.

To describe locale for (O - object):
    carry out the printing the locale description activity with O.

To set the/-- locale priority of (O - an object) to (N - a number):
    if O is a thing:
        if N <= 0, now O is mentioned;
        if there is a notable-object of O in the Table of Locale Priorities:
            choose row with a notable-object of O in the Table of Locale Priorities;
            if N <= 0, blank out the whole row;
            otherwise change the locale description priority entry to N;
        otherwise:
```

```
if N is greater than 0:
    choose a blank row in the Table of Locale Priorities;
    change the notable-object entry to 0;
    change the locale description priority entry to N;
```

§**22. Printing the Locale Description.** This is handled by the "printing the locale description" activity. The before stage works out which objects might be of interest; the for stage actually prints paragraphs; the after stage is initially empty, but can be used to insert all kinds of interesting information into a room description.

We count the paragraphs printed in a global variable, not an activity variable, since it needs to be consulted in sub-activities whose rules are outside what would be its scope; that doesn't matter, though, since locale descriptions are not nested. (If they were, the above table would fail in any case.)

(1) Disaster would ensue if the user tampered with the "initialise locale description rule", but nobody is likely to do this other than intentionally.
(2) The "find notable locale objects rule" in fact only runs a further activity, the "choosing notable locale objects" activity. The task here is to identify the objects which might by virtue of their location appear in the locale, and to assign each of them a priority number.
(3) The "interesting locale paragraphs rule" goes through all of the notable objects chosen at stage (2), in order of priority, and offers each to yet another activity: the "printing a locale paragraph about" activity. This can either print a paragraph related to the item in question, or demote it as being not even nondescript (by changing its priority to 0). The default is to do nothing, in which case the item becomes nondescript.
(4) The "you-can-also-see rule" prints what is, ordinarily, the final paragraph of the locale description, listing the nondescript items. It goes to some trouble to find out whether these all have a common object tree parent, listing them with "list contents of" if they do: this is so that people who have written rules such as "Rule for printing the name of the blur while listing contents..." will take effect, because the "listing contents" activity will be going on. Provided that the notable objects chosen in (2) are all children of the locale domain, this will always happen. If the user should add rules to make quite different objects also notable, then the "you-can-also-see rule" has to resort to listing in a way which doesn't use the "listing contents" activity – since the list is not in fact a list of the contents of anything.

```
Printing the locale description of something (documented at act_pld) is an activity.

The locale paragraph count is a number that varies.

Before printing the locale description (this is the initialise locale description rule):
    now the locale paragraph count is 0;
    repeat with item running through things:
        now the item is not mentioned;
    repeat through the Table of Locale Priorities:
        blank out the whole row.

Before printing the locale description (this is the find notable locale objects rule):
    let the domain be the parameter-object;
    carry out the choosing notable locale objects activity with the domain;
    continue the activity.

For printing the locale description (this is the interesting locale paragraphs rule):
    let the domain be the parameter-object;
    sort the Table of Locale Priorities in locale description priority order;
    repeat through the Table of Locale Priorities:
        [say "[notable-object entry]...";]
        carry out the printing a locale paragraph about activity with the notable-object entry;
    continue the activity.

For printing the locale description (this is the you-can-also-see rule):
```

```
let the domain be the parameter-object;
let the mentionable count be 0;
repeat with item running through things:
    now the item is not marked for listing;
repeat through the Table of Locale Priorities:
    [say "[notable-object entry] - [locale description priority entry].";]
    if the locale description priority entry is greater than 0,
        now the notable-object entry is marked for listing;
    increase the mentionable count by 1;
if the mentionable count is greater than 0:
    repeat with item running through things:
        if the item is mentioned:
            now the item is not marked for listing;
    begin the listing nondescript items activity;
    if the number of marked for listing things is 0:
        abandon the listing nondescript items activity;
    otherwise:
        if handling the listing nondescript items activity:
            if the domain is a room:
                if the domain is the location, say "You ";
                otherwise say "In [the domain] you ";
            otherwise if the domain is a supporter:
                say "On [the domain] you ";
            otherwise if the domain is an animal:
                say "On [the domain] you ";
            otherwise:
                say "In [the domain] you ";
            say "can [if the locale paragraph count is greater than 0]also [end if]see ";
            let the common holder be nothing;
            let contents form of list be true;
            repeat with list item running through marked for listing things:
                if the holder of the list item is not the common holder:
                    if the common holder is nothing,
                        now the common holder is the holder of the list item;
                    otherwise now contents form of list is false;
                if the list item is mentioned, now the list item is not marked for listing;
            filter list recursion to unmentioned things;
            if contents form of list is true and the common holder is not nothing,
                list the contents of the common holder, as a sentence, including contents,
                    giving brief inventory information, tersely, not listing
                    concealed items, listing marked items only;
            otherwise say "[a list of marked for listing things including contents]";
            if the domain is the location, say " here";
            say ".[paragraph break]";
            unfilter list recursion;
        end the listing nondescript items activity;
continue the activity.
```

§**23. Choosing Notable Locale Objects.** By default, the notable objects are exactly the children of the domain, and they all have equal priority (1). Since table sorting is stable, and thus preserves the row order of rows with equal priority, the eventual order of listing is by default the same as the order in which things are added to the table, which in turn is the object-tree traversal order.

```
Choosing notable locale objects of something (documented at act_cnlo) is an activity.

For choosing notable locale objects (this is the standard notable locale objects rule):
    let the domain be the parameter-object;
    let the held item be the first thing held by the domain;
    while the held item is a thing:
        set the locale priority of the held item to 5;
        now the held item is the next thing held after the held item;
    continue the activity.
```

§**24. Printing a Locale Paragraph.** By default there are four kinds of "interesting" locale paragraph, and the following setup is fairly complicated because it implements conventions gradually built up between 1978 and 2008.

To recap, this activity is run on each notable thing in turn, in priority order. (It is only run on notable things for efficiency reasons.)

The basic principle is that, at every stage, we should consider an item only if it is not "mentioned" already. This will happen if it has been named by a previous paragraph, but also if it has been explicitly marked as such to get rid of it. In considering an item, we have three basic options:

(a) Print a paragraph about the item and mark it as mentioned – this is good for interesting items deserving a paragraph of their own.
(b) Print a paragraph, but do not mark it as mentioned – this is only likely to be useful if we want to print information related to the item without mentioning the thing itself. (For instance, if the presence of a mysterious parcel resulted in a ticking noise, we could print a paragraph about the ticking noise without mentioning the parcel, which would then appear later.)
(c) Mark the item as mentioned but print nothing – this gets rid of the item, ensuring that it will not appear in the final "you can also see" sentence, and will not be considered by subsequent rules.
(d) Do nothing at all – the item then becomes "nondescript" and appears in the final "you can also see" sentence, unless somebody else mentions it in the mean time.

Briefly, then, the following is the standard method:

(1) The "don't mention player's supporter in room descriptions rule" excludes anything the player is directly or indirectly standing on or, less frequently, in. The header of the room description has probably already said something like "Boudoir (on the four-poster bed)", so the player can't be unaware of this item.
(2) The "don't mention scenery in room descriptions rule" excludes scenery.
(3) The "don't mention undescribed items in room descriptions rule" excludes the player object. (It's redundant to say "You can also see yourself here.") At present nothing else in I7 is "undescribed" in this sense.
(4) The "set pronouns from items in room descriptions rule" adjusts the meaning of pronouns like IT and HER to pick up items mentioned. Thus if a room description ends "Mme Tourmalet glares at you.", then HER would be adjusted to mean Mme Tourmalet.
(5) The "offer items to writing a paragraph about rule" gives the "printing a paragraph about" activity a chance to intervene. We detect whether it does intervene or not by looking to see if it has printed any text.
(6) The "use initial appearance in room descriptions rule" uses the initial appearance property of an object which has never been handled as a paragraph.
(7) The "describe what's on scenery supporters in room descriptions rule" is a somewhat controversial feature: whereas the rest of Inform's room description conventions are generally consensus, this one is much disliked by some users for its occasional inappropriateness. It prints text such as "On the

mantelpiece is a piece of chalk." for items which, like the mantelpiece, are scenery mentioned (we assume) in the main room description. (It is assumed that scenery supporters make their contents more prominently visible than scenery containers, which we do not announce the contents of.) The ability to modify, replace or abolish this rule was one of the main motivations to break room description up into activities in March 2008.

```
Printing a locale paragraph about something (documented at act_plp) is an activity.

For printing a locale paragraph about a thing (called the item)
    (this is the don't mention player's supporter in room descriptions rule):
    if the item encloses the player, set the locale priority of the item to 0;
    continue the activity.

For printing a locale paragraph about a thing (called the item)
    (this is the don't mention scenery in room descriptions rule):
    if the item is scenery, set the locale priority of the item to 0;
    continue the activity.

For printing a locale paragraph about a thing (called the item)
    (this is the don't mention undescribed items in room descriptions rule):
    if the item is undescribed, set the locale priority of the item to 0;
    continue the activity.

For printing a locale paragraph about a thing (called the item)
    (this is the set pronouns from items in room descriptions rule):
    if the item is not mentioned, set pronouns from the item;
    continue the activity.

For printing a locale paragraph about a thing (called the item)
    (this is the offer items to writing a paragraph about rule):
    if the item is not mentioned:
        if a paragraph break is pending, say "[conditional paragraph break]";
        carry out the writing a paragraph about activity with the item;
        if a paragraph break is pending:
            increase the locale paragraph count by 1;
            now the item is mentioned;
            say "[command clarification break]";
    continue the activity.

For printing a locale paragraph about a thing (called the item)
    (this is the use initial appearance in room descriptions rule):
    if the item is not mentioned:
        if the item provides the property initial appearance and the
            item is not handled:
            increase the locale paragraph count by 1;
            say "[initial appearance of the item]";
            say "[paragraph break]";
            if a locale-supportable thing is on the item:
                repeat with possibility running through things on the item:
                    now the possibility is marked for listing;
                    if the possibility is mentioned:
                        now the possibility is not marked for listing;
                say "On [the item] ";
                list the contents of the item, as a sentence, including contents,
                    giving brief inventory information, tersely, not listing
                    concealed items, prefacing with is/are, listing marked items only;
                say ".[paragraph break]";
            now the item is mentioned;
```

```
    continue the activity.

Definition: a thing (called the item) is locale-supportable if the item is not
scenery and the item is not mentioned and the item is not undescribed.

For printing a locale paragraph about a thing (called the item)
    (this is the describe what's on scenery supporters in room descriptions rule):
    if the item is not undescribed and the item is scenery and
        the item does not enclose the player:
        set pronouns from the item;
        if a locale-supportable thing is on the item:
            repeat with possibility running through things on the item:
                now the possibility is marked for listing;
                if the possibility is mentioned:
                    now the possibility is not marked for listing;
            increase the locale paragraph count by 1;
            say "On [the item] ";
            list the contents of the item, as a sentence, including contents,
                giving brief inventory information, tersely, not listing
                concealed items, prefacing with is/are, listing marked items only;
            say ".[paragraph break]";
    continue the activity.
```

SR4 - Actions A/sr4

Purpose

The standard stock of actions supplied with Inform, along with the rules which define them; and the Understand grammar which corresponds to them.

---

§**1.** NI comes with no actions built in, and only one (perhaps unexpected) assumption: that the 8th action defined is "going".

The order, and the subheadings, here are responsible for the order and subheadings used in the Actions page of the Index.

```
Part SR4 - Actions

Section SR4/1 - Generic action patterns

Section SR4/2 - Standard actions concerning the actor's possessions
```

§2. Taking inventory.

```
Taking inventory is an action with past participle taken, applying to nothing.
The taking inventory action translates into I6 as "Inv".

The specification of the taking inventory action is "Taking an inventory of
one's immediate possessions: the things being carried, either directly or in
any containers being carried. When the player performs this action, either
the inventory listing, or else a special message if nothing is being carried
or worn, is printed during the carry out rules: nothing happens at the report
stage. The opposite happens for other people performing the action: nothing
happens during carry out, but a report such as 'Mr X looks through his
possessions.' is produced (provided Mr X is visible).

The exotic 'use inventory to set pronouns rule' allows the inventory
listing to change the current meanings of IT, HIM, HER, and so on for the
player's future commands. Thus if the player is carrying a certain female
cat, say, taking inventory might print up the name 'Missee Lee', and this
would set HER to refer to Missee Lee. Some IF authors dislike this
convention: it can be abolished by writing 'The use inventory to set
pronouns rule is not listed in any rulebook.'"
```

§**3.** Missee Lee is a black and white cat living in North Oxford, named for a Cambridge-educated pirate queen in the South China seas who is the heroine – or villainess – of the tenth in Arthur Ransome's Swallows and Amazons series of children's books, *Missee Lee* (1941). Since you ask.

§**4.** Carry out.

```
Carry out taking inventory (this is the print empty inventory rule):
    if the first thing held by the player is nothing, stop the action with
        library message taking inventory action number 1.

Carry out taking inventory (this is the print standard inventory rule):
    issue library message taking inventory action number 2;
    say ":[line break]";
    list the contents of the player, with newlines, indented, including contents,
        giving inventory information, with extra indentation.

Carry out taking inventory (this is the use inventory to set pronouns rule):
    set pronouns from possessions of the player.
```

§**5.** Report.

```
Report an actor taking inventory (this is the report other people taking
    inventory rule):
    if the actor is not the player,
        issue actor-based library message taking inventory action number 5 for the actor.
```

§6. Taking.

```
Taking is an action with past participle taken, applying to one thing.
The taking action translates into I6 as "Take".

The specification of the taking action is "The taking action is the only way
an action in the Standard Rules can cause something to be carried by an actor.
It is very simple in operation (the entire carry out stage consists only of
'now the actor carries the noun') but many checks must be performed before it
can be allowed to happen."
```

§7. Check.

```
Check an actor taking (this is the can't take yourself rule):
    if the actor is the noun, stop the action with library message taking
        action number 2 for the noun.

Check an actor taking (this is the can't take other people rule):
    if the noun is a person, stop the action with library message taking
        action number 3 for the noun.

Check an actor taking (this is the can't take component parts rule):
    if the noun is part of something (called the whole), stop the action
        with library message taking action number 7 for the whole.

Check an actor taking (this is the can't take people's possessions rule):
    let the local ceiling be the common ancestor of the actor with the noun;
    let H be the not-counting-parts holder of the noun;
    while H is not nothing and H is not the local ceiling:
        if H is a person, stop the action with library message taking action
            number 6 for H;
        let H be the not-counting-parts holder of H;

Check an actor taking (this is the can't take items out of play rule):
    let H be the noun;
    while H is not nothing and H is not a room:
        let H be the not-counting-parts holder of H;
    if H is nothing, stop the action with library message taking action
        number 8 for the noun.

Check an actor taking (this is the can't take what you're inside rule):
    let the local ceiling be the common ancestor of the actor with the noun;
    if the local ceiling is the noun, stop the action with library message
        taking action number 4 for the noun.

Check an actor taking (this is the can't take what's already taken rule):
    if the actor is carrying the noun, stop the action with library message
        taking action number 5 for the noun;
    if the actor is wearing the noun, stop the action with library message
        taking action number 5 for the noun.

Check an actor taking (this is the can't take scenery rule):
    if the noun is scenery, stop the action with library message taking
        action number 10 for the noun.

Check an actor taking (this is the can only take things rule):
    if the noun is not a thing, stop the action with library message taking
        action number 15 for the noun.

Check an actor taking (this is the can't take what's fixed in place rule):
```

```
    if the noun is fixed in place, stop the action with library message taking
        action number 11 for the noun.

Check an actor taking (this is the use player's holdall to avoid exceeding
    carrying capacity rule):
    if the number of things carried by the actor is at least the
        carrying capacity of the actor:
        if the actor is holding a player's holdall (called the current working sack):
            let the transferred item be nothing;
            repeat with the possible item running through things carried by
                the actor:
                if the possible item is not lit and the possible item is not
                    the current working sack, let the transferred item be the possible item;
            if the transferred item is not nothing:
                issue library message taking action number 13 for the
                    transferred item;
                silently try the actor trying inserting the transferred item
                    into the current working sack;
                if the transferred item is not in the current working sack, stop the action;

Check an actor taking (this is the can't exceed carrying capacity rule):
    if the number of things carried by the actor is at least the
        carrying capacity of the actor, stop the action with library
        message taking action number 12 for the actor.
```

§8. Carry out.

```
Carry out an actor taking (this is the standard taking rule):
    now the actor carries the noun.
```

§9. Report.

```
Report an actor taking (this is the standard report taking rule):
    if the actor is the player, issue library message taking action number 1
        for the noun;
    otherwise issue actor-based library message taking action number 16 for the noun.
```

§10. Removing it from.

```
Removing it from is an action applying to two things.
The removing it from action translates into I6 as "Remove".

The specification of the removing it from action is "Removing is not really
an action in its own right. Whereas there are many ways to put something down
(on the floor, on top of something, inside something else, giving it to
somebody else, and so on), Inform has only one way to take something: the
taking action. Removing exists only to provide some nicely worded replies
to impossible requests, and in all sensible cases is converted into taking.
Because of this, it's usually a bad idea to write rules about removing:
if you write a rule such as 'Instead of removing the key, ...' then it
won't apply if the player simply types TAKE KEY instead. The safe way to
do this is to write a rule about taking, which covers all possibilities."
```

§11. Check.

```
Check an actor removing something from (this is the can't remove what's not inside rule):
    if the holder of the noun is not the second noun, stop the action with
        library message removing it from action number 2 for the noun.

Check an actor removing something from (this is the can't remove from people rule):
    if the holder of the noun is a person (called the owner), stop the action with
        library message taking action number 6 for the owner.

Check an actor removing something from (this is the convert remove to take rule):
    convert to the taking action on the noun.

The can't take component parts rule is listed before the can't remove what's not
inside rule in the check removing it from rules.
```

§12. Dropping.

```
Dropping is an action applying to one thing.
The dropping action translates into I6 as "Drop".

The specification of the dropping action is "Dropping is one of five actions
by which an actor can get rid of something carried: the others are inserting
(into a container), putting (onto a supporter), giving (to someone else) and
eating. Dropping means dropping onto the actor's current floor, which is
usually the floor of a room - but might be the inside of a box if the actor
is also inside that box, and so on.

The can't drop clothes being worn rule silently tries the taking off action
on any clothing being dropped: unlisting this rule removes both this behaviour
and also the requirement that clothes cannot simply be dropped."
```

§13. Check.

```
Check an actor dropping (this is the can't drop yourself rule):
    if the noun is the actor, stop the action with library message putting
        it on action number 4.

Check an actor dropping (this is the can't drop what's already dropped rule):
    if the noun is in the holder of the actor, stop the action with library
        message dropping action number 1 for the noun.

Check an actor dropping (this is the can't drop what's not held rule):
    if the actor is carrying the noun, continue the action;
    if the actor is wearing the noun, continue the action;
    stop the action with library message dropping action number 2 for the noun.

Check an actor dropping (this is the can't drop clothes being worn rule):
    if the actor is wearing the noun:
        issue library message dropping action number 3 for the noun;
        silently try the actor trying taking off the noun;
        if the actor is wearing the noun, stop the action;

Check an actor dropping (this is the can't drop if this exceeds carrying
    capacity rule):
    let H be the holder of the actor;
    if H is a room, continue the action; [room floors have infinite capacity]
    if H provides the property carrying capacity:
        if H is a supporter:
            if the number of things on H is at least the carrying capacity of H:
                if the actor is the player,
                    issue library message dropping action number 5 for H;
                stop the action;
        otherwise if H is a container:
            if the number of things in H is at least the carrying capacity of H:
                if the actor is the player,
                    issue library message dropping action number 6 for H;
                stop the action;
```

§**14.** Carry out.

```
Carry out an actor dropping (this is the standard dropping rule):
    now the noun is in the holder of the actor.
```

§**15.** Report.

```
Report an actor dropping (this is the standard report dropping rule):
    if the actor is the player, issue library message dropping action number 4
        for the noun;
    otherwise issue actor-based library message dropping action number 7 for the noun.
```

§16. Putting it on.

```
Putting it on is an action with past participle put, applying to two things.
The putting it on action translates into I6 as "PutOn".

The specification of the putting it on action is "By this action, an actor puts
something he is holding on top of a supporter: for instance, putting an apple
on a table."
```

§17. Check.

```
Check an actor putting something on (this is the convert put to drop where possible rule):
    if the second noun is down or the actor is on the second noun,
        convert to the dropping action on the noun.

Check an actor putting something on (this is the can't put what's not held rule):
    if the actor is carrying the noun, continue the action;
    if the actor is wearing the noun, continue the action;
    stop the action with library message putting it on action number 1 for the noun.

Check an actor putting something on (this is the can't put something on itself rule):
    let the noun-CPC be the component parts core of the noun;
    let the second-CPC be the component parts core of the second noun;
    let the transfer ceiling be the common ancestor of the noun-CPC with the second-CPC;
    if the transfer ceiling is the noun-CPC,
        stop the action with library message putting it on action number 2 for
            the noun.

Check an actor putting something on (this is the can't put onto what's not a supporter rule):
    if the second noun is not a supporter,
        stop the action with library message putting it on action number 3 for
            the second noun.

Check an actor putting something on (this is the can't put onto something being carried rule):
    if the actor encloses the second noun,
        stop the action with library message putting it on action number 4 for
            the second noun.

Check an actor putting something on (this is the can't put clothes being worn rule):
    if the actor is wearing the noun:
        issue library message putting it on action number 5 for the noun;
        silently try the actor trying taking off the noun;
        if the actor is wearing the noun, stop the action;

Check an actor putting something on (this is the can't put if this exceeds
    carrying capacity rule):
    if the second noun provides the property carrying capacity:
        if the number of things on the second noun is at least the carrying capacity
            of the second noun,
            stop the action with library message putting it on action number 6 for
            the second noun;
```

§18. Carry out.

```
Carry out an actor putting something on (this is the standard putting rule):
    now the noun is on the second noun.
```

§**19.** Report.

```
Report an actor putting something on (this is the concise report putting rule):
    if the actor is the player and the I6 parser is running multiple actions,
        stop the action with library message putting it on action number 7
        for the noun;
    otherwise continue the action.

Report an actor putting something on (this is the standard report putting rule):
    if the actor is the player, issue library message putting it on action
        number 8 for the noun;
    otherwise issue actor-based library message putting it on action
        number 9 for the noun.
```

§20. Inserting it into.

```
Inserting it into is an action applying to two things.
The inserting it into action translates into I6 as "Insert".

The specification of the inserting it into action is "By this action, an actor puts
something he is holding into a container: for instance, putting a coin into a
collection box."
```

§21. Check.

```
Check an actor inserting something into (this is the convert insert to drop where
    possible rule):
    if the second noun is down or the actor is in the second noun,
        convert to the dropping action on the noun.

Check an actor inserting something into (this is the can't insert what's not held rule):
    if the actor is carrying the noun, continue the action;
    if the actor is wearing the noun, continue the action;
    stop the action with library message inserting it into action number 1 for
        the noun.

Check an actor inserting something into (this is the can't insert something into itself rule):
    let the noun-CPC be the component parts core of the noun;
    let the second-CPC be the component parts core of the second noun;
    let the transfer ceiling be the common ancestor of the noun-CPC with the second-CPC;
    if the transfer ceiling is the noun-CPC,
        stop the action with library message inserting it into action number 5 for
            the noun.

Check an actor inserting something into (this is the can't insert into closed containers rule):
    if the second noun is a closed container,
        stop the action with library message inserting it into action number 3 for
            the second noun.

Check an actor inserting something into (this is the can't insert into what's not a
    container rule):
    if the second noun is not a container,
        stop the action with library message inserting it into action number 2 for
            the second noun.

Check an actor inserting something into (this is the can't insert clothes being worn rule):
    if the actor is wearing the noun:
        issue library message inserting it into action number 6 for the noun;
        silently try the actor trying taking off the noun;
        if the actor is wearing the noun, stop the action;

Check an actor inserting something into (this is the can't insert if this exceeds
    carrying capacity rule):
    if the second noun provides the property carrying capacity:
        if the number of things in the second noun is at least the carrying capacity
        of the second noun,
            stop the action with library message inserting it into action number 7 for
                the second noun;
```

§22. Carry out.

```
Carry out an actor inserting something into (this is the standard inserting rule):
    now the noun is in the second noun.
```

§23. Report.

```
Report an actor inserting something into (this is the concise report inserting rule):
    if the actor is the player and the I6 parser is running multiple actions,
        stop the action with library message inserting it into action number 8
        for the noun;
    otherwise continue the action.

Report an actor inserting something into (this is the standard report inserting rule):
    if the actor is the player, issue library message inserting it into action
        number 9 for the noun;
    otherwise issue actor-based library message inserting it into action number 10 for the noun.
```

§24. Eating.

```
Eating is an action with past participle eaten, applying to one carried thing.
The eating action translates into I6 as "Eat".

The specification of the eating action is "Eating is the only one of the
built-in actions which can, in effect, destroy something: the carry out
rule removes what's being eaten from play, and nothing in the Standard
Rules can then get at it again.

Note that, uncontroversially, one can only eat things with the 'edible'
either/or property, and also that, more controversially, one can only
eat things currently being held. This means that a player standing next
to a bush with berries who types EAT BERRIES will force a '(first taking
the berries)' action."
```

§25. Check.

```
Check an actor eating (this is the can't eat unless edible rule):
    if the noun is not a thing or the noun is not edible,
        stop the action with library message eating action number 1 for the noun.

Check an actor eating (this is the can't eat clothing without removing it first rule):
    if the actor is wearing the noun:
        issue library message dropping action number 3 for the noun;
        try the actor trying taking off the noun;
        if the actor is wearing the noun, stop the action;
```

§26. Carry out.

```
Carry out an actor eating (this is the standard eating rule):
    remove the noun from play.
```

§27. Report.

```
Report an actor eating (this is the standard report eating rule):
    if the actor is the player, issue library message eating action number 2
        for the noun;
    otherwise issue actor-based library message eating action number 3 for the noun.
```

§28. Going.

```
Section SR4/3 - Standard actions which move the actor

Going is an action with past participle gone, applying to one visible thing.
The going action translates into I6 as "Go".

The specification of the going action is "This is the action which allows people
to move from one room to another, using whatever map connections and doors are
to hand. The Standard Rules are written so that the noun can be either a
direction or a door in the location of the actor: while the player's commands
only lead to going actions with directions as nouns, going actions can also
happen as a result of entering actions, and then the noun can indeed be
a door."

The going action has a room called the room gone from (matched as "from").
The going action has an object called the room gone to (matched as "to").
The going action has an object called the door gone through (matched as "through").
The going action has an object called the vehicle gone by (matched as "by").
The going action has an object called the thing gone with (matched as "with").

Rule for setting action variables for going (this is the standard set going variables rule):
    now the thing gone with is the item-pushed-between-rooms;
    now the room gone from is the location of the actor;
    if the actor is in an enterable vehicle (called the carriage),
        now the vehicle gone by is the carriage;
    let the target be nothing;
    if the noun is a direction:
        let direction D be the noun;
        let the target be the room-or-door direction D from the room gone from;
    otherwise:
        if the noun is a door, let the target be the noun;
    if the target is a door:
        now the door gone through is the target;
        now the target is the other side of the target from the room gone from;
    now the room gone to is the target.
```

§29. Check.

```
Check an actor going (this is the can't travel in what's not a vehicle rule):
    let H be the holder of the actor;
    if H is the room gone from, continue the action;
    if H is the vehicle gone by, continue the action;
    stop the action with library message going action number 1 for H.

Check an actor going (this is the can't go through undescribed doors rule):
    if the door gone through is not nothing and the door gone through is undescribed,
        stop the action with library message going action number 2 for the room gone from.

Check an actor going (this is the can't go through closed doors rule):
    if the door gone through is not nothing and the door gone through is closed:
        if the noun is up, stop the action with library message going action number 3
            for the door gone through;
        if the noun is down, stop the action with library message going action number 4
            for the door gone through;
        stop the action with library message going action number 5 for the door gone
            through;
```

```
Check an actor going (this is the determine map connection rule):
    let the target be nothing;
    if the noun is a direction:
        let direction D be the noun;
        let the target be the room-or-door direction D from the room gone from;
    otherwise:
        if the noun is a door, let the target be the noun;
    if the target is a door:
        now the target is the other side of the target from the room gone from;
    now the room gone to is the target.
Check an actor going (this is the can't go that way rule):
    if the room gone to is nothing:
        if the door gone through is nothing, stop the action with library
            message going action number 2 for the room gone from;
        stop the action with library message going action number 6 for the door gone through;
```

§30. Carry out.

```
Carry out an actor going (this is the move player and vehicle rule):
    if the vehicle gone by is nothing,
        surreptitiously move the actor to the room gone to during going;
    otherwise
        surreptitiously move the vehicle gone by to the room gone to during going.
Carry out an actor going (this is the move floating objects rule):
    if the actor is the player,
        update backdrop positions.
Carry out an actor going (this is the check light in new location rule):
    if the actor is the player,
        surreptitiously reckon darkness.
```

§31. Report.

```
Report an actor going (this is the describe room gone into rule):
    if the player is the actor:
        produce a room description with going spacing conventions;
    otherwise:
        if the noun is a direction:
            if the location is the room gone from:
                if the location is the room gone to:
                    continue the action;
                otherwise:
                    if the noun is up :
                        issue actor-based library message going action number 8;
                    otherwise if the noun is down:
                        issue actor-based library message going action number 9;
                    otherwise:
                        issue actor-based library message going action number 10 for the noun;
            otherwise:
                let the back way be the opposite of the noun;
                if the location is the room gone to:
                    let the room back the other way be the room back way from the
```

```
                location;
            let the room normally this way be the room noun from the
                room gone from;
            if the room back the other way is the room gone from or
                the room back the other way is the room normally this way:
                if the back way is up:
                    issue actor-based library message going action number 11;
                otherwise if the back way is down:
                    issue actor-based library message going action number 12;
                otherwise:
                    issue actor-based library message going action number 13
                        for the back way;
            otherwise:
                issue actor-based library message going action number 14;
        otherwise:
            if the back way is up :
                issue actor-based library message going action number 15
                    for the room gone to;
            otherwise if the back way is down:
                issue actor-based library message going action number 16
                    for the room gone to;
            otherwise:
                issue actor-based library message going action number 17
                    for the room gone to and the back way;
otherwise if the location is the room gone from:
    issue actor-based library message going action number 18 for the noun;
otherwise:
    issue actor-based library message going action number 19 for the noun;
if the vehicle gone by is not nothing:
    say " ";
    if the vehicle gone by is a supporter, issue actor-based library message
        going action number 20 for the vehicle gone by;
    otherwise issue actor-based library message going action number 21
        for the vehicle gone by;
if the thing gone with is not nothing:
    if the player is within the thing gone with:
        issue actor-based library message going action number 22 for the thing gone with;
    otherwise if the player is within the vehicle gone by:
        issue actor-based library message going action number 23 for the thing gone with;
    otherwise if the location is the room gone from:
        issue actor-based library message going action number 24 for the thing gone with;
    otherwise:
        issue actor-based library message going action number 25 for the thing gone with;
if the player is within the vehicle gone by and the player is not
    within the thing gone with:
    issue actor-based library message going action number 26;
    say ".";
    try looking;
    continue the action;
say ".";
```

§32. Entering.

```
Entering is an action applying to one thing.
The entering action translates into I6 as "Enter".

The specification of the entering action is "Whereas the going action allows
people to move from one location to another in the model world, the entering
action is for movement inside a location: for instance, climbing into a cage
or sitting on a couch. (Entering is not allowed to change location, so any
attempt to enter a door is converted into a going action.) What makes
entering trickier than it looks is that the player may try to enter an
object which is itself inside, or part of, something else, which might in
turn be... and so on. To preserve realism, the implicitly pass through other
barriers rule automatically generates entering and exiting actions needed
to pass between anything which might be in the way: for instance, in a
room with two open cages, an actor in cage A who tries entering cage B first
has to perform an exiting action."
```

§33. Check.

```
Check an actor entering (this is the convert enter door into go rule):
    if the noun is a door, convert to the going action on the noun.

Check an actor entering (this is the convert enter compass direction into go rule):
    if the noun is a direction, convert to the going action on the noun.

Check an actor entering (this is the can't enter what's already entered rule):
    let the local ceiling be the common ancestor of the actor with the noun;
    if the local ceiling is the noun, stop the action with library message
        entering action number 1 for the noun.

Check an actor entering (this is the can't enter what's not enterable rule):
    if the noun is not enterable, stop the action with library message
        entering action number 2 for the noun.

Check an actor entering (this is the can't enter closed containers rule):
    if the noun is a closed container, stop the action with library message
        entering action number 3 for the noun.

Check an actor entering (this is the can't enter something carried rule):
    let the local ceiling be the common ancestor of the actor with the noun;
    if the local ceiling is the actor, stop the action with library message
        entering action number 4 for the noun.

Check an actor entering (this is the implicitly pass through other barriers rule):
    if the holder of the actor is the holder of the noun, continue the action;
    let the local ceiling be the common ancestor of the actor with the noun;
    while the holder of the actor is not the local ceiling:
        let the target be the holder of the actor;
        issue library message entering action number 6 for the target;
        silently try the actor trying exiting;
        if the holder of the actor is the target, stop the action;
    if the holder of the actor is the noun, stop the action;
    if the holder of the actor is the holder of the noun, continue the action;
    let the target be the holder of the noun;
    if the noun is part of the target, let the target be the holder of the target;
    while the target is a thing:
        if the holder of the target is the local ceiling:
```

```
            issue library message entering action number 7 for the target;
            silently try the actor trying entering the target;
            if the holder of the actor is not the target, stop the action;
            convert to the entering action on the noun;
            continue the action;
        let the target be the holder of the target;
```

§**34.** Carry out.

```
Carry out an actor entering (this is the standard entering rule):
    surreptitiously move the actor to the noun.
```

§**35.** Report.

```
Report an actor entering (this is the standard report entering rule):
    if the actor is the player:
        issue library message entering action number 5 for the noun;
    otherwise if the noun is a container:
        issue actor-based library message entering action number 8 for the noun;
    otherwise:
        issue actor-based library message entering action number 9 for the noun;
    continue the action.

Report an actor entering (this is the describe contents entered into rule):
    if the actor is the player, describe locale for the noun.
```

§36. Exiting.

```
Exiting is an action applying to nothing.
The exiting action translates into I6 as "Exit".
The exiting action has an object called the container exited from.

The specification of the exiting action is "Whereas the going action allows
people to move from one location to another in the model world, and the
entering action is for movement deeper inside the objects in a location,
the exiting action is for movement back out towards the main floor area.
Climbing out of a cupboard, for instance, is an exiting action. Exiting
when already in the main floor area of a room with a map connection to
the outside is converted to a going action. Finally, note that whereas
entering works for either containers or supporters, exiting is purely for
getting oneself out of containers: if the actor is on top of a supporter
instead, an exiting action is converted to the getting off action."

Setting action variables for exiting:
    now the container exited from is the holder of the actor.
```

§37. Check.

```
Check an actor exiting (this is the convert exit into go out rule):
    let the local room be the location of the actor;
    if the container exited from is the local room:
        if the room-or-door outside from the local room is not nothing,
            convert to the going action on the outside;

Check an actor exiting (this is the can't exit when not inside anything rule):
    let the local room be the location of the actor;
    if the container exited from is the local room, stop the action with
        library message exiting action number 1 for the actor.

Check an actor exiting (this is the can't exit closed containers rule):
    if the actor is in a closed container (called the cage), stop the action
        with library message exiting action number 2 for the cage.

Check an actor exiting (this is the convert exit into get off rule):
    if the actor is on a supporter (called the platform),
        convert to the getting off action on the platform.
```

§38. Carry out.

```
Carry out an actor exiting (this is the standard exiting rule):
    let the former exterior be the not-counting-parts holder of the container exited from;
    surreptitiously move the actor to the former exterior.
```

§**39.** Report.

```
Report an actor exiting (this is the standard report exiting rule):
    if the actor is the player:
        issue library message exiting action number 3 for the container exited from;
    otherwise:
        issue actor-based library message exiting action number 6 for the container exited from;
    continue the action.

Report an actor exiting (this is the describe room emerged into rule):
    if the actor is the player,
        produce a room description with going spacing conventions.
```

§40. Getting off.

```
Getting off is an action with past participle got, applying to one thing.
The getting off action translates into I6 as "GetOff".

The specification of the getting off action is "The getting off action is for
actors who are currently on top of a supporter: perhaps standing on a platform,
but maybe only sitting on a chair or even lying down in bed. Unlike the similar
exiting action, getting off takes a noun: the platform, chair, bed or what
have you."
```

§41. Check.

```
Check an actor getting off (this is the can't get off things rule):
    if the actor is on the noun, continue the action;
    if the actor is carried by the noun, continue the action;
    stop the action with library message getting off action number 1 for the noun.
```

§42. Carry out.

```
Carry out an actor getting off (this is the standard getting off rule):
    let the former exterior be the not-counting-parts holder of the noun;
    surreptitiously move the actor to the former exterior.
```

§43. Report.

```
Report an actor getting off (this is the standard report getting off rule):
    if the actor is the player:
        issue library message exiting action number 3 for the noun;
    otherwise:
        issue actor-based library message exiting action number 5 for the noun;
    continue the action.

Report an actor getting off (this is the describe room stood up into rule):
    if the actor is the player,
        produce a room description with going spacing conventions.
```

§44. Looking.

```
Section SR4/4 - Standard actions concerning the actor's vision

Looking is an action applying to nothing.
The looking action translates into I6 as "Look".

The specification of the looking action is "The looking action describes the
player's current room and any visible items, but is made more complicated
by the problem of visibility. Inform calculates this by dividing the room
into visibility levels. For an actor on the floor of a room, there is only
one such level: the room itself. But an actor sitting on a chair inside
a packing case which is itself on a gantry would have four visibility levels:
chair, case, gantry, room. The looking rules use a special phrase, 'the
visibility-holder of X', to go up from one level to the next: thus the
visibility-holder of the case is the gantry.

The 'visibility level count' is the number of levels which the player can
actually see, and the 'visibility ceiling' is the uppermost visible level.
For a player standing on the floor of a lighted room, this will be a count
of 1 with the ceiling set to the room. But a player sitting on a chair in
a closed opaque packing case would have visibility level count 2, and
visibility ceiling equal to the case. Moreover, light has to be available
in order to see anything at all: if the player is in darkness, the level
count is 0 and the ceiling is nothing.

Finally, note that several actions other than looking also produce room
descriptions in some cases. The most familiar is going, but exiting a
container or getting off a supporter will also generate a room description.
(The phrase used by the relevant rules is 'produce a room description with
going spacing conventions' and carry out or report rules for newly written
actions are welcome to use this too if they would like to. The spacing
conventions affect paragraph division, and note that the main description
paragraph may be omitted for a place not newly visited, depending on the
VERBOSE settings.) Room descriptions like this are produced by running the
check, carry out and report rules for looking, but are not subject to
before, instead or after rules: so they do not count as a new action. The
looking variable 'room-describing action' holds the action name of the
reason a room description is currently being made: if the player typed
LOOK, this will indeed be set to the looking action, but if we're
describing a room just reached by GO EAST, say, it will be set to the going
action. This can be used to customise carry out looking rules so that
different forms of description are used on going to a room as compared with
looking around while already there."

The looking action has an action-name called the room-describing action.
The looking action has a truth state called abbreviated form allowed.
The looking action has a number called the visibility level count.
The looking action has an object called the visibility ceiling.

Setting action variables for looking (this is the determine visibility ceiling
    rule):
    if the actor is the player, calculate visibility ceiling at low level;
    now the visibility level count is the visibility ceiling count calculated;
    now the visibility ceiling is the visibility ceiling calculated;
    now the room-describing action is the looking action.
```

§**45.** Carry out.

```
Carry out looking (this is the room description heading rule):
    say bold type;
    if the visibility level count is 0:
        begin the printing the name of a dark room activity;
        if handling the printing the name of a dark room activity,
            issue miscellaneous library message number 71;
        end the printing the name of a dark room activity;
    otherwise if the visibility ceiling is the location:
        say "[visibility ceiling]";
    otherwise:
        say "[The visibility ceiling]";
    say roman type;
    let intermediate level be the visibility-holder of the actor;
    repeat with intermediate level count running from 2 to the visibility level count:
        issue library message looking action number 8 for the intermediate level;
        let the intermediate level be the visibility-holder of the intermediate level;
    say line break;
    say run paragraph on with special look spacing.

Carry out looking (this is the room description body text rule):
    if the visibility level count is 0:
        if set to abbreviated room descriptions, continue the action;
        if set to sometimes abbreviated room descriptions and
            abbreviated form allowed is true and
            darkness witnessed is true,
            continue the action;
        begin the printing the description of a dark room activity;
        if handling the printing the description of a dark room activity,
            issue miscellaneous library message number 17;
        end the printing the description of a dark room activity;
    otherwise if the visibility ceiling is the location:
        if set to abbreviated room descriptions, continue the action;
        if set to sometimes abbreviated room descriptions and abbreviated form
            allowed is true and the location is visited, continue the action;
        print the location's description;

Carry out looking (this is the room description paragraphs about objects rule):
    if the visibility level count is greater than 0:
        let the intermediate position be the actor;
        let the IP count be the visibility level count;
        while the IP count is greater than 0:
            now the intermediate position is marked for listing;
            let the intermediate position be the visibility-holder of the
                intermediate position;
            decrease the IP count by 1;
        let the top-down IP count be the visibility level count;
        while the top-down IP count is greater than 0:
            let the intermediate position be the actor;
            let the IP count be 0;
            while the IP count is less than the top-down IP count:
                let the intermediate position be the visibility-holder of the
                    intermediate position;
                increase the IP count by 1;
```

```
            [if we ever support I6-style inside descriptions, here's where]
            describe locale for the intermediate position;
            decrease the top-down IP count by 1;
    continue the action;
Carry out looking (this is the check new arrival rule):
    if in darkness:
        now the darkness witnessed is true;
    otherwise:
        if the location is a room, now the location is visited;
```

§46. Report.

```
Report an actor looking (this is the other people looking rule):
    if the actor is not the player,
        issue actor-based library message looking action number 9.
```

§47. Examining.

```
Examining is an action applying to one visible thing and requiring light.
The examining action translates into I6 as "Examine".

The specification of the examining action is "The act of looking closely at
something. Note that the noun could be either a direction or a thing, which
is why the Standard Rules include the 'examine directions rule' to deal with
directions: it simply says 'You see nothing unexpected in that direction.'
and stops the action. (If you would like to handle directions differently,
list another rule instead of this one in the carry out examining rules.)

For arcane reasons to do with the Inform 6 library underlying what Inform
does, these rules test to see 'if the noun goes undescribed by source
text' (rather than more simply testing whether the description property
of the noun is blank). If so, we search (i.e., look inside) a container,
and show the status (switched on or off) of a device, but otherwise
give up with a bland response. For traditional reasons, we also show
the status of a device as a second paragraph even after any description
property has been printed: this is done by the examine described devices
rule."
```

§48. Carry out.

```
Carry out examining (this is the examine undescribed containers rule):
    if the noun goes undescribed by source text and
        the noun is a container,
        convert to the searching action on the noun.

Carry out examining (this is the examine undescribed devices rule):
    if the noun goes undescribed by source text and
        the noun is a device,
        stop the action with library message examining action number 3
            for the noun.

Carry out examining (this is the examine undescribed things rule):
    if the noun goes undescribed by source text,
        stop the action with library message examining action number 2
            for the noun.

Carry out examining (this is the examine directions rule):
    if the noun is a direction,
        stop the action with library message examining action number 5
            for the noun.

Carry out examining (this is the standard examining rule):
    say "[the description of the noun][line break]".

Carry out examining (this is the examine described devices rule):
    if the noun is a device,
        stop the action with library message examining action number 3
            for the noun.
```

§49. Report.

```
Report an actor examining (this is the report other people examining rule):
    if the actor is not the player,
        issue actor-based library message examining action number 4 for the noun.
```

§50. Looking under.

```
Looking under is an action applying to one visible thing and requiring light.
The looking under action translates into I6 as "LookUnder".

The specification of the looking under action is "The standard Inform world
model does not have a concept of things being under other things, so this
action is only minimally provided by the Standard Rules, but it exists here
for traditional reasons (and because, after all, LOOK UNDER TABLE is the
sort of command which ought to be recognised even if it does nothing useful).
The action ordinarily either tells the player he finds nothing of interest,
or reports that somebody else has looked under something.

The usual way to make this action do something useful is to write a rule
like 'Instead of looking under the cabinet for the first time: now the
player has the silver key; say ...' and so on."
```

§51. Carry out.

```
Carry out an actor looking under (this is the standard looking under rule):
    stop the action with library message looking under action number 2 for
        the noun.
```

§52. Report.

```
Report an actor looking under (this is the report other people looking under rule):
    if the actor is not the player,
        issue actor-based library message looking under action number 3 for the noun.
```

§53. Searching.

```
Searching is an action applying to one thing and requiring light.
The searching action translates into I6 as "Search".

The specification of the searching action is "Searching looks at the contents
of an open or transparent container, or at the items on top of a supporter.
These are often mentioned in room descriptions already, and then the action
is unnecessary, but that wouldn't be true for something like a kitchen
cupboard which is scenery - mentioned in passing in a room description, but
not made a fuss of. Searching such a cupboard would then, by listing its
contents, give the player more information than the ordinary room description
shows.

The usual check rules restrict searching to containers and supporters: so
the Standard Rules do not allow the searching of people, for instance. But
it is easy to add instead rules ('Instead of searching Dr Watson: ...') or
even a new carry out rule ('Check searching someone (called the suspect): ...')
to extend the way searching normally works."
```

§54. Check.

```
Check an actor searching (this is the can't search unless container or supporter rule):
    if the noun is not a container and the noun is not a supporter,
        stop the action with library message searching action number 4 for
            the noun.

Check an actor searching (this is the can't search closed opaque containers rule):
    if the noun is a closed opaque container,
        stop the action with library message searching action number 5 for
            the noun.
```

§55. Report.

```
Report searching a container (this is the standard search containers rule):
    if the noun contains a described thing which is not scenery,
        issue library message searching action number 7 for the noun;
    otherwise
        issue library message searching action number 6 for the noun.

Report searching a supporter (this is the standard search supporters rule):
    if the noun supports a described thing which is not scenery,
        issue library message searching action number 3 for the noun;
    otherwise
        issue library message searching action number 2 for the noun.

Report an actor searching (this is the report other people searching rule):
    if the actor is not the player,
        issue actor-based library message searching action number 8 for the noun.
```

§56. Consulting it about.

```
Consulting it about is an action applying to one thing and one topic.
The consulting it about action translates into I6 as "Consult".

The specification of the consulting it about action is "Consulting is a very
flexible and potentially powerful action, but only because it leaves almost
all of the work to the author to deal with directly. The idea is for it to
respond to commands such as LOOK UP HENRY FITZROY IN HISTORY BOOK, where
the topic would be the snippet of command HENRY FITZROY and the thing would
be the book.

The Standard Rules simply parry such requests by saying that the player finds
nothing of interest. All interesting responses must be provided by the author,
using rules like 'Instead of consulting the history book about...'"
```

§57. Report.

```
Report an actor consulting something about (this is the block consulting rule):
    if the actor is the player,
        issue library message consulting it about action number 1 for the noun;
    otherwise
        issue actor-based library message consulting it about action number 2 for the noun.
```

§58. Locking it with.

```
Section SR4/5 - Standard actions which change the state of things

Locking it with is an action applying to one thing and one carried thing.
The locking it with action translates into I6 as "Lock".

The specification of the locking it with action is "Locking is the act of
using an object such as a key to ensure that something such as a door or
container cannot be opened unless first unlocked. (Only closed things can be
locked.)

Locking can be performed on any kind of thing which provides the either/or
properties lockable, locked, openable and open. The 'can't lock without a lock
rule' tests to see if the noun both provides the lockable property, and if
it is in fact lockable: it is then assumed that the other properties can
safely be checked. In the Standard Rules, the container and door kinds both
satisfy these requirements.

We can create a new kind on which opening, closing, locking and unlocking
will work thus: 'A briefcase is a kind of thing. A briefcase can be openable.
A briefcase can be open. A briefcase can be lockable. A briefcase can be
locked. A briefcase is usually openable, lockable, open and unlocked.'

Inform checks whether the key fits using the 'can't lock without the correct
key rule'. To satisfy this, the actor must be directly holding the second
noun, and it must be the current value of the 'matching key' property for
the noun. (This property is seldom referred to directly because it is
automatically set by assertions like 'The silver key unlocks the wicket
gate.')

The Standard Rules provide locking and unlocking actions at a fairly basic
level: they can be much enhanced using the extension Locksmith by Emily
Short, which is included with all distributions of Inform."
```

§59. Check.

```
Check an actor locking something with (this is the can't lock without a lock rule):
    if the noun provides the property lockable and the noun is lockable,
        continue the action;
    stop the action with library message locking it with action number 1 for the noun.

Check an actor locking something with (this is the can't lock what's already
    locked rule):
    if the noun is locked,
        stop the action with library message locking it with action number 2 for the noun.

Check an actor locking something with (this is the can't lock what's open rule):
    if the noun is open,
        stop the action with library message locking it with action number 3 for the noun.

Check an actor locking something with (this is the can't lock without the correct key rule):
    if the holder of the second noun is not the actor or
        the noun does not provide the property matching key or
        the matching key of the noun is not the second noun,
        stop the action with library message locking it with action number 4 for the second noun.
```

§**60.** Carry out.

```
Carry out an actor locking something with (this is the standard locking rule):
    now the noun is locked.
```

§**61.** Report.

```
Report an actor locking something with (this is the standard report locking rule):
    if the actor is the player:
        issue library message locking it with action number 5 for the noun;
    otherwise:
        if the actor is visible, issue actor-based library message locking it with
            action number 6 for the noun;
```

§62. Unlocking it with.

```
Unlocking it with is an action applying to one thing and one carried thing.
The unlocking it with action translates into I6 as "Unlock".

The specification of the unlocking it with action is "Unlocking undoes the
effect of locking, and renders the noun openable again provided that the
actor is carrying the right key (which must be the second noun).

Unlocking can be performed on any kind of thing which provides the either/or
properties lockable, locked, openable and open. The 'can't unlock without a lock
rule' tests to see if the noun both provides the lockable property, and if
it is in fact lockable: it is then assumed that the other properties can
safely be checked. In the Standard Rules, the container and door kinds both
satisfy these requirements.

We can create a new kind on which opening, closing, locking and unlocking
will work thus: 'A briefcase is a kind of thing. A briefcase can be openable.
A briefcase can be open. A briefcase can be lockable. A briefcase can be
locked. A briefcase is usually openable, lockable, open and unlocked.'

Inform checks whether the key fits using the 'can't unlock without the correct
key rule'. To satisfy this, the actor must be directly holding the second
noun, and it must be the current value of the 'matching key' property for
the noun. (This property is seldom referred to directly because it is
automatically set by assertions like 'The silver key unlocks the wicket
gate.')

The Standard Rules provide locking and unlocking actions at a fairly basic
level: they can be much enhanced using the extension Locksmith by Emily
Short, which is included with all distributions of Inform."
```

§63. Check.

```
Check an actor unlocking something with (this is the can't unlock without a lock rule):
    if the noun provides the property lockable and the noun is lockable,
        continue the action;
    stop the action with library message unlocking it with action number 1 for the noun.

Check an actor unlocking something with (this is the can't unlock what's already unlocked rule):
    if the noun is not locked,
        stop the action with library message unlocking it with action number 2 for the noun.

Check an actor unlocking something with (this is the can't unlock without the correct key rule):
    if the holder of the second noun is not the actor or
        the noun does not provide the property matching key or
        the matching key of the noun is not the second noun,
        stop the action with library message unlocking it with action number 3 for the
            second noun.
```

§64. Carry out.

```
Carry out an actor unlocking something with (this is the standard unlocking rule):
    now the noun is not locked.
```

§**65.** Report.

```
Report an actor unlocking something with (this is the standard report unlocking rule):
    if the actor is the player:
        issue library message unlocking it with action number 4 for the noun;
    otherwise:
        if the actor is visible, issue actor-based library message unlocking it with
            action number 5 for the noun;
```

§66. Switching on.

```
Switching on is an action applying to one thing.
The switching on action translates into I6 as "SwitchOn".

The specification of the switching on action is "The switching on and switching
off actions are for the simplest kind of machinery operation: they are for
objects representing machines (or more likely parts of machines), which are
considered to be either off or on at any given time.

The actions are intended to be used where the noun is a device, but in fact
they could work just as well with any kind which can be 'switched on' or
'switched off'."
```

§67. Check.

```
Check an actor switching on (this is the can't switch on unless switchable rule):
    if the noun provides the property switched on, continue the action;
    stop the action with library message switching on action number 1 for the noun.

Check an actor switching on (this is the can't switch on what's already on rule):
    if the noun is switched on,
        stop the action with library message switching on action number 2 for the noun.
```

§68. Carry out.

```
Carry out an actor switching on (this is the standard switching on rule):
    now the noun is switched on.
```

§69. Report.

```
Report an actor switching on (this is the standard report switching on rule):
    if the actor is the player, issue library message switching on action number 3
        for the noun;
    otherwise issue actor-based library message switching on action number 4 for the noun;
```

§70. Switching off.

```
Switching off is an action applying to one thing.
The switching off action translates into I6 as "SwitchOff".

The specification of the switching off action is "The switching off and switching
on actions are for the simplest kind of machinery operation: they are for
objects representing machines (or more likely parts of machines), which are
considered to be either off or on at any given time.

The actions are intended to be used where the noun is a device, but in fact
they could work just as well with any kind which can be 'switched on' or
'switched off'."
```

§71. Check.

```
Check an actor switching off (this is the can't switch off unless switchable rule):
    if the noun provides the property switched on, continue the action;
    stop the action with library message switching off action number 1 for the noun.

Check an actor switching off (this is the can't switch off what's already off rule):
    if the noun is switched off,
        stop the action with library message switching off action number 2 for the noun.
```

§72. Carry out.

```
Carry out an actor switching off (this is the standard switching off rule):
    now the noun is switched off.
```

§73. Report.

```
Report an actor switching off (this is the standard report switching off rule):
    if the actor is the player, issue library message switching off action number 3
        for the noun;
    otherwise issue actor-based library message switching off action number 4 for the noun;
```

§74. Opening.

```
Opening is an action applying to one thing.
The opening action translates into I6 as "Open".

The specification of the opening action is "Opening makes something no longer
a physical barrier. The action can be performed on any kind of thing which
provides the either/or properties openable and open. The 'can't open unless
openable rule' tests to see if the noun both can be and actually is openable.
(It is assumed that anything which can be openable can also be open.)
In the Standard Rules, the container and door kinds both satisfy these
requirements.

In the event that the thing to be opened is also lockable, we are forbidden
to open it when it is locked. Both containers and doors can be lockable,
but the opening and closing actions would also work fine with kinds which
cannot be.

We can create a new kind on which opening and closing will work thus:
'A case file is a kind of thing. A case file can be openable.
A case file can be open. A case file is usually openable and closed.'

The meaning of open and closed is different for different kinds of thing.
When a container is closed, that means people outside cannot reach in,
and vice versa; when a door is closed, people cannot use the 'going' action
to pass through it. If we were to create a new kind such as 'case file',
we would also need to write rules to make the open and closed properties
interesting for this kind."
```

§75. Check.

```
Check an actor opening (this is the can't open unless openable rule):
    if the noun provides the property openable and the noun is openable,
        continue the action;
    stop the action with library message opening action number 1 for the noun.

Check an actor opening (this is the can't open what's locked rule):
    if the noun provides the property lockable and the noun is locked,
        stop the action with library message opening action number 2 for the noun.

Check an actor opening (this is the can't open what's already open rule):
    if the noun is open,
        stop the action with library message opening action number 3 for the noun.
```

§76. Carry out.

```
Carry out an actor opening (this is the standard opening rule):
    now the noun is open.
```

§**77.** Report.

```
Report an actor opening (this is the reveal any newly visible interior rule):
    if the actor is the player and
        the noun is an opaque container and
        the first thing held by the noun is not nothing and
        the noun does not enclose the actor,
        stop the action with library message opening action number 4 for the noun.
Report an actor opening (this is the standard report opening rule):
    if the actor is the player:
        issue library message opening action number 5 for the noun;
    otherwise if the player can see the actor:
        issue actor-based library message opening action number 6 for the noun;
    otherwise:
        issue actor-based library message opening action number 7 for the noun;
```

§78. Closing.

```
Closing is an action applying to one thing.
The closing action translates into I6 as "Close".

The specification of the closing action is "Closing makes something into
a physical barrier. The action can be performed on any kind of thing which
provides the either/or properties openable and open. The 'can't close unless
openable rule' tests to see if the noun both can be and actually is openable.
(It is assumed that anything which can be openable can also be open, and
hence can also be closed.) In the Standard Rules, the container and door
kinds both satisfy these requirements.

We can create a new kind on which opening and closing will work thus:
'A case file is a kind of thing. A case file can be openable.
A case file can be open. A case file is usually openable and closed.'

The meaning of open and closed is different for different kinds of thing.
When a container is closed, that means people outside cannot reach in,
and vice versa; when a door is closed, people cannot use the 'going' action
to pass through it. If we were to create a new kind such as 'case file',
we would also need to write rules to make the open and closed properties
interesting for this kind."
```

§79. Check.

```
Check an actor closing (this is the can't close unless openable rule):
    if the noun provides the property openable and the noun is openable,
        continue the action;
    stop the action with library message closing action number 1 for the noun.

Check an actor closing (this is the can't close what's already closed rule):
    if the noun is closed,
        stop the action with library message closing action number 2 for the noun.
```

§80. Carry out.

```
Carry out an actor closing (this is the standard closing rule):
    now the noun is closed.
```

§81. Report.

```
Report an actor closing (this is the standard report closing rule):
    if the actor is the player:
        issue library message closing action number 3 for the noun;
    otherwise if the player can see the actor:
        issue actor-based library message closing action number 4 for the noun;
    otherwise:
        issue actor-based library message closing action number 5 for the noun;
```

§82. Wearing.

```
Wearing is an action with past participle worn, applying to one carried thing.
The wearing action translates into I6 as "Wear".

The specification of the wearing action is "The Standard Rules give Inform
only a simple model of clothing. A thing can be worn only if it has the
either/or property of being 'wearable'. (Typing a sentence like 'Mr Jones
wears the Homburg hat.' automatically implies that the hat is wearable,
which is why we only seldom need to use the word 'wearable' directly.)
There is no checking of how much or how little any actor is wearing, or
how incongruous this may appear: nor any distinction between under or
over-clothes.

To put on an article of clothing, the actor must be directly carrying it,
as enforced by the 'can't wear what's not held rule'."
```

§83. Check.

```
Check an actor wearing (this is the can't wear what's not clothing rule):
    if the noun is not a thing or the noun is not wearable,
        stop the action with library message wearing action number 1 for the noun.

Check an actor wearing (this is the can't wear what's not held rule):
    if the holder of the noun is not the actor,
        stop the action with library message wearing action number 2 for the noun.

Check an actor wearing (this is the can't wear what's already worn rule):
    if the actor is wearing the noun,
        stop the action with library message wearing action number 3 for the noun.
```

§84. Carry out.

```
Carry out an actor wearing (this is the standard wearing rule):
    now the actor wears the noun.
```

§85. Report.

```
Report an actor wearing (this is the standard report wearing rule):
    if the actor is the player, issue library message wearing action number 4
        for the noun;
    otherwise issue actor-based library message wearing action number 5
        for the noun.
```

§86. Taking off.

```
Taking off is an action with past participle taken, applying to one carried thing.
The taking off action translates into I6 as "Disrobe".

The specification of the taking off action is "The Standard Rules give Inform
only a simple model of clothing. A thing can be worn only if it has the
either/or property of being 'wearable'. (Typing a sentence like 'Mr Jones
wears the Homburg hat.' automatically implies that the hat is wearable,
which is why we only seldom need to use the word 'wearable' directly.)
There is no checking of how much or how little any actor is wearing, or
how incongruous this may appear: nor any distinction between under or
over-clothes.

When an article of clothing is taken off, it becomes a thing directly
carried by its former wearer, rather than being (say) dropped onto the floor."
```

§87. Check.

```
Check an actor taking off (this is the can't take off what's not worn rule):
    if the actor is not wearing the noun,
        stop the action with library message taking off action number 1 for the noun.
```

§88. Carry out.

```
Carry out an actor taking off (this is the standard taking off rule):
    now the actor carries the noun.
```

§89. Report.

```
Report an actor taking off (this is the standard report taking off rule):
    if the actor is the player, issue library message taking off action number 2
        for the noun;
    otherwise issue actor-based library message taking off action number 3 for the noun.
```

§90. Giving it to.

```
Section SR4/6 - Standard actions concerning other people

Giving it to is an action with past participle given, applying to one carried thing and one thing.
The giving it to action translates into I6 as "Give".

The specification of the giving it to action is "This action is indexed by
Inform under 'Actions concerning other people', but it could just as easily
have gone under 'Actions concerning the actor's possessions' because -
like dropping, putting it on or inserting it into - this is an action
which gets rid of something being carried.

The Standard Rules implement this action fully - if it reaches the carry
out and report rulebooks, then the item is indeed transferred to the
recipient, and this is properly reported. But giving something to
somebody is not like putting something on a shelf: the recipient has
to agree. The final check rule, the 'block giving rule', assumes that
the recipient does not consent - so the gift fails to happen. The way
to make the giving action use its abilities fully is to replace the
block giving rule with a rule which makes a more sophisticated decision
about who will accept what from whom, and only blocks some attempts,
letting others run on into the carry out and report rules."
```

§91. Check.

```
Check an actor giving something to (this is the can't give what you haven't got rule):
    if the actor is not the holder of the noun,
        stop the action with library message giving it to action number 1 for the noun.

Check an actor giving something to (this is the can't give to yourself rule):
    if the actor is the second noun,
        stop the action with library message giving it to action number 2 for the noun.

Check an actor giving something to (this is the can't give to a non-person rule):
    if the second noun is not a person,
        stop the action with library message giving it to action number 4 for the
            second noun.

Check an actor giving something to (this is the block giving rule):
    stop the action with library message giving it to action number 3 for the
        second noun.
```

§92. Carry out.

```
Carry out an actor giving something to (this is the standard giving rule):
    move the noun to the second noun.
```

§93. Report.

```
Report an actor giving something to (this is the standard report giving rule):
    if the actor is the player:
        issue library message giving it to action number 5 for the noun;
    otherwise if the second noun is the player:
        issue actor-based library message giving it to action number 6 for the noun;
    otherwise:
        issue actor-based library message giving it to action number 7 for the noun;
```

§94. Showing it to.

```
Showing it to is an action with past participle shown, applying to one carried thing
    and one visible thing.
The showing it to action translates into I6 as "Show".

The specification of the showing it to action is "Anyone can show anyone
else something which they are carrying, but not some nearby piece of
scenery, say - so this action is suitable for showing the emerald locket
to Katarina, but not showing the Orange River Rock Room to Mr Douglas.

The Standard Rules implement this action in only a minimal way, checking
that it makes sense but then blocking all such attempts with a message
such as 'Katarina is not interested.' - this is the task of the 'block
showing rule'. As a result, there are no carry out or report rules. To
make it into a systematic and interesting action, we would need to
unlist the block showing rule and then to write carry out and report
rules: but usually for IF purposes we only need to make a handful of
special cases of showing work properly, and for those we can simply
write Instead rules to handle them."
```

§95. Check.

```
Check an actor showing something to (this is the can't show what you haven't
    got rule):
    if the actor is not the holder of the noun,
        stop the action with library message showing it to action number 1
            for the noun.

Check an actor showing something to (this is the convert show to yourself to
    examine rule):
    if the actor is the second noun,
        convert to the examining action on the noun.

Check an actor showing something to (this is the block showing rule):
    stop the action with library message showing it to action number 2
        for the second noun.
```

§96. Waking.

```
Waking is an action with past participle woken, applying to one thing.
The waking action translates into I6 as "WakeOther".

The specification of the waking action is "This is the act of jostling
a sleeping person to wake him or her up, and it finds its way into the
Standard Rules only for historical reasons. Inform does not by default
provide any model for people being asleep or awake, so this action does
not do anything in the standard implementation: instead, it is always
stopped by the block waking rule."
```

§97. Check.

```
Check an actor waking (this is the block waking rule):
    stop the action with library message waking action number 1 for the noun.
```

§98. Throwing it at.

```
Throwing it at is an action with past participle thrown, applying to one carried
    thing and one visible thing.
The throwing it at action translates into I6 as "ThrowAt".

The specification of the throwing it at action is "Throwing something at
someone or something is difficult for Inform to model. So many considerations
apply: just because the actor can see the target, does it follow that the
target can accurately hit it? What if the projectile is heavy, like an
anvil, or something not easily aimable, like a feather? What if there
is a barrier in the way, like a cage with bars spaced so that only items
of a certain size get through? And then: what should happen as a result?
Will the projectile break, or do damage, or fall to the floor, or into
a container or onto a supporter? And so on.

Because it seems hopeless to try to model this in any general way,
Inform instead provides the action for the user to attach specific rules to.
The check rules in the Standard Rules simply require that the projectile
is not an item of clothing still worn (this will be relevant for women
attending a Tom Jones concert) but then, in either the 'futile to throw
things at inanimate objects rule' or the 'block throwing at rule', will
refuse to carry out the action with a bland message.

To make throwing do something, then, we must either write Instead rules
for special circumstances, or else unlist these check rules and write
suitable carry out and report rules to pick up the thread."
```

§99. Check.

```
Check an actor throwing something at (this is the implicitly remove thrown clothing rule):
    if the actor is wearing the noun:
        issue library message dropping action number 3 for the noun;
        silently try the actor trying taking off the noun;
        if the actor is wearing the noun, stop the action;

Check an actor throwing something at (this is the futile to throw things at inanimate
    objects rule):
    if the second noun is not a person,
        stop the action with library message throwing it at action number 1
            for the second noun.

Check an actor throwing something at (this is the block throwing at rule):
    stop the action with library message throwing it at action number 2
        for the noun.
```

§100. Attacking.

```
Attacking is an action applying to one thing.
The attacking action translates into I6 as "Attack".

The specification of the attacking action is "Violence is seldom the answer,
and attempts to attack another person are normally blocked as being unrealistic
or not seriously meant. (I might find a shop assistant annoying, but IF is
not Grand Theft Auto, and responding by killing him is not really one of
my options.) So the Standard Rules simply block attempts to fight people,
but the action exists for rules to make exceptions."
```

§101. Check.

```
Check an actor attacking (this is the block attacking rule):
    stop the action with library message attacking action number 1 for the noun.
```

§102. Kissing.

```
Kissing is an action applying to one thing.
The kissing action translates into I6 as "Kiss".

The specification of the kissing action is "Possibly because Inform was
originally written by an Englishman, attempts at kissing another person are
normally blocked as being unrealistic or not seriously meant. So the
Standard Rules simply block attempts to kiss people, but the action exists
for rules to make exceptions."
```

§103. Check.

```
Check an actor kissing (this is the kissing yourself rule):
    if the noun is the actor,
        stop the action with library message touching action number 3 for the noun.

Check an actor kissing (this is the block kissing rule):
    stop the action with library message kissing action number 1 for the noun.
```

§104. Answering it that.

```
Answering it that is an action applying to one thing and one topic.
The answering it that action translates into I6 as "Answer".

The specification of the answering it that action is "The Standard Rules do
not include any systematic way to handle conversation: instead, Inform is
set up so that it is as easy as we can make it to write specific rules
handling speech in particular games, and so that if no such rules are
written then all attempts to communicate are gracefully if not very
interestingly rejected.

The topic here can be any double-quoted text, which can itself contain
tokens in square brackets: see the documentation on Understanding.

Answering is an action existing so that the player can say something free-form
to somebody else. A convention of IF is that a command such as DAPHNE, TAKE
MASK is a request to Daphne to perform an action: if the persuasion rules in
force mean that she consents, the action 'Daphne taking the mask' does
indeed then result. But if the player types DAPHNE, 12375 or DAPHNE, GREAT
HEAVENS - or anything else not making sense as a command - the action
'answering Daphne that ...' will be generated.

The name of the action arises because it is also caused by typing, say,
ANSWER 12375 when Daphne (say) has asked a question."
```

§105. Report.

```
Report an actor answering something that (this is the block answering rule):
    stop the action with library message answering it that action number 1
        for the noun.
```

§106. Telling it about.

```
Telling it about is an action with past participle told, applying to one thing and one topic.
The telling it about action translates into I6 as "Tell".

The specification of the telling it about action is "The Standard Rules do
not include any systematic way to handle conversation: instead, Inform is
set up so that it is as easy as we can make it to write specific rules
handling speech in particular games, and so that if no such rules are
written then all attempts to communicate are gracefully if not very
interestingly rejected.

The topic here can be any double-quoted text, which can itself contain
tokens in square brackets: see the documentation on Understanding.

Telling is an action existing only to catch commands like TELL ALEX ABOUT
GUITAR. Customarily in IF, such a command is shorthand which the player
accepts as a conventional form: it means 'tell Alex what I now know about
the guitar' and would make sense if the player had himself recently
discovered something significant about the guitar which might interest
Alex."
```

§107. Check.

```
Check an actor telling something about (this is the telling yourself rule):
    if the actor is the noun,
        stop the action with library message telling it about action number 1
            for the noun.
```

§108. Report.

```
Report an actor telling something about (this is the block telling rule):
    stop the action with library message telling it about action number 2
        for the noun.
```

§109. Asking it about.

```
Asking it about is an action applying to one thing and one topic.
The asking it about action translates into I6 as "Ask".

The specification of the asking it about action is "The Standard Rules do
not include any systematic way to handle conversation: instead, Inform is
set up so that it is as easy as we can make it to write specific rules
handling speech in particular games, and so that if no such rules are
written then all attempts to communicate are gracefully if not very
interestingly rejected.

The topic here can be any double-quoted text, which can itself contain
tokens in square brackets: see the documentation on Understanding.

Asking is an action existing only to catch commands like ASK STEPHEN ABOUT
PENELOPE. Customarily in IF, such a command is shorthand which the player
accepts as a conventional form: it means 'engage Mary in conversation and
try to find out what she might know about'. It's understood as a convention
of the genre that Mary should not be expected to respond in cases where
there is no reason to suppose that she has anything relevant to pass on -
ASK JANE ABOUT RICE PUDDING, for instance, need not conjure up a recipe
even if Jane is a 19th-century servant and therefore almost certainly
knows one."
```

§110. Report.

```
Report an actor asking something about (this is the block asking rule):
    stop the action with library message asking it about action number 1
        for the noun.
```

§111. Asking it for.

```
Asking it for is an action applying to two things.
The asking it for action translates into I6 as "AskFor".

The specification of the asking it for action is "The Standard Rules do
not include any systematic way to handle conversation, but this is
action is not quite conversation: it doesn't involve any spoken text as
such. It exists to catch commands like ASK SALLY FOR THE EGG WHISK,
where the whisk is something which Sally has and the player can see.

Slightly oddly, but for historical reasons, an actor asking himself for
something is treated to an inventory listing instead. All other cases
are converted to the giving action: that is, ASK SALLY FOR THE EGG WHISK
is treated as if it were SALLY, GIVE ME THE EGG WHISK - an action for
Sally to perform and which then follows rules for giving.

To ask for information or something intangible, see the asking it about
action."
```

§112. Check.

```
Check an actor asking something for (this is the asking yourself for something rule):
    if the actor is the noun and the actor is the player,
        try taking inventory instead.

Check an actor asking something for (this is the translate asking for to giving rule):
    convert to request of the noun to perform giving it to action with the
        second noun and the actor.
```

§113. Waiting.

```
Section SR4/7 - Standard actions which are checked but then do nothing unless rules intervene

Waiting is an action applying to nothing.
The waiting action translates into I6 as "Wait".

The specification of the waiting action is "The inaction action: where would
we be without waiting? Waiting does not cause time to pass by - that happens
anyway - but represents a positive choice by the actor not to fill that time.
It is an action so that rules can be attached to it: for instance, we could
imagine that a player who consciously decides to sit and wait might notice
something which a busy player does not, and we could write a rule accordingly.

Note the absence of check or carry out rules - anyone can wait, at any time,
and it makes nothing happen."
```

§114. Report.

```
Report an actor waiting (this is the standard report waiting rule):
    if the actor is the player, stop the action with library message waiting
        action number 1 for the actor;
    issue actor-based library message waiting action number 2.
```

§115. Touching.

```
Touching is an action applying to one thing.
The touching action translates into I6 as "Touch".

The specification of the touching action is "Touching is just that, touching
something without applying pressure: a touch-sensitive screen or a living
creature might react, but a standard push-button or lever will probably not.

In the Standard Rules there are no check touching rules, since touchability
is already a requirement of the noun for the action anyway, and no carry out
rules because nothing in the standard Inform world model reacts to
a mere touch - though report rules do mean that attempts to touch other
people provoke a special reply."
```

§116. Report.

```
Report an actor touching (this is the report touching yourself rule):
    if the noun is the actor:
        if the actor is the player, issue library message touching action number 3
            for the noun;
        otherwise issue actor-based library message touching action number 4;
        stop the action;
    continue the action.

Report an actor touching (this is the report touching other people rule):
    if the noun is a person:
        if the actor is the player:
            issue library message touching action number 1 for the noun;
        otherwise if the noun is the player:
            issue actor-based library message touching action number 5;
        otherwise:
            issue actor-based library message touching action number 6 for the noun;
        stop the action;
    continue the action.

Report an actor touching (this is the report touching things rule):
    if the actor is the player, issue library message touching action number 2
        for the noun;
    otherwise issue actor-based library message touching action number 6 for the noun.
```

§117. Waving.

```
Waving is an action applying to one thing.
The waving action translates into I6 as "Wave".

The specification of the waving action is "Waving in this sense is like
waving a sceptre: the item to be waved must be directly held (or worn)
by the actor.

In the Standard Rules there are no carry out rules for this action because
nothing in the standard Inform world model which reacts to it. The action
is provided for authors to hang more interesting behaviour onto for special
cases: say, waving a particular rusty iron rod with a star on the end."
```

§118. Check.

```
Check an actor waving (this is the can't wave what's not held rule):
    if the actor is not the holder of the noun,
        stop the action with library message waving action number 1 for the noun.
```

§119. Report.

```
Report an actor waving (this is the report waving things rule):
    if the actor is the player, issue library message waving action number 2
        for the noun;
    otherwise issue actor-based library message waving action number 3 for the noun.
```

§120. Pulling.

```
Pulling is an action applying to one thing.
The Pulling action translates into I6 as "Pull".

The specification of the pulling action is "Pulling is the act of pulling
something not grossly larger than the actor by an amount which would not
substantially move it.

In the Standard Rules there are no carry out rules for this action because
nothing in the standard Inform world model which reacts to it. The action
is provided for authors to hang more interesting behaviour onto for special
cases: say, pulling a lever. ('The big red lever is a fixed in place device.
Instead of pulling the big red lever, try switching on the lever. Instead
of pushing the big red lever, try switching off the lever.')"
```

§121. Check.

```
Check an actor pulling (this is the can't pull what's fixed in place rule):
    if the noun is fixed in place,
        stop the action with library message pulling action number 1 for the noun.

Check an actor pulling (this is the can't pull scenery rule):
    if the noun is scenery,
        stop the action with library message pulling action number 2 for the noun.

Check an actor pulling (this is the can't pull people rule):
    if the noun is a person,
        stop the action with library message pulling action number 4 for the noun.
```

§122. Report.

```
Report an actor pulling (this is the report pulling rule):
    if the actor is the player, issue library message pulling action number 3
        for the noun;
    otherwise issue actor-based library message pulling action number 5 for the noun.
```

§123. Pushing.

```
Pushing is an action applying to one thing.
The Pushing action translates into I6 as "Push".

The specification of the pushing action is "Pushing is the act of pushing
something not grossly larger than the actor by an amount which would not
substantially move it. (See also the pushing it to action, which involves
a longer-distance push between rooms.)

In the Standard Rules there are no carry out rules for this action because
nothing in the standard Inform world model which reacts to it. The action
is provided for authors to hang more interesting behaviour onto for special
cases: say, pulling a lever. ('The big red lever is a fixed in place device.
Instead of pulling the big red lever, try switching on the lever. Instead
of pushing the big red lever, try switching off the lever.')"
```

§124. Check.

```
Check an actor pushing something (this is the can't push what's fixed in place rule):
    if the noun is fixed in place,
        stop the action with library message pushing action number 1 for the noun.

Check an actor pushing something (this is the can't push scenery rule):
    if the noun is scenery,
        stop the action with library message pushing action number 2 for the noun.

Check an actor pushing something (this is the can't push people rule):
    if the noun is a person,
        stop the action with library message pushing action number 4 for the noun.
```

§125. Report.

```
Report an actor pushing something (this is the report pushing rule):
    if the actor is the player, issue library message pushing action number 3
        for the noun;
    otherwise issue actor-based library message pushing action number 6 for the noun.
```

§126. Turning.

```
Turning is an action applying to one thing.
The Turning action translates into I6 as "Turn".

The specification of the turning action is "Turning is the act of rotating
something - say, a dial.

In the Standard Rules there are no carry out rules for this action because
nothing in the standard Inform world model which reacts to it. The action
is provided for authors to hang more interesting behaviour onto for special
cases: say, turning a capstan."
```

§127. Check.

```
Check an actor turning (this is the can't turn what's fixed in place rule):
    if the noun is fixed in place,
        stop the action with library message turning action number 1 for the noun.
Check an actor turning (this is the can't turn scenery rule):
    if the noun is scenery,
        stop the action with library message turning action number 2 for the noun.
Check an actor turning (this is the can't turn people rule):
    if the noun is a person,
        stop the action with library message turning action number 4 for the noun.
```

§128. Report.

```
Report an actor turning (this is the report turning rule):
    if the actor is the player, issue library message turning action number 3
        for the noun;
    otherwise issue actor-based library message turning action number 7 for the noun.
```

§129. Pushing it to.

```
Pushing it to is an action applying to one thing and one visible thing.
The Pushing it to action translates into I6 as "PushDir".

The specification of the pushing it to action is "This action covers pushing
a large object, not being carried, so that the actor pushes it from one room
to another: for instance, pushing a bale of hay to the east.

This is rapidly converted into a special form of the going action. If the
noun object has the either/or property 'pushable between rooms', then the
action is converted to going by the 'standard pushing in directions rule'.
If that going action succeeds, then the original pushing it to action
stops; it's only if that fails that we run on into the 'block pushing in
directions rule', which then puts an end to the matter."
```

§130. Check.

```
Check an actor pushing something to (this is the can't push unpushable things rule):
    if the noun is not pushable between rooms,
        stop the action with library message pushing it to action number 1 for
            the noun.

Check an actor pushing something to (this is the can't push to non-directions rule):
    if the second noun is not a direction,
        stop the action with library message pushing it to action number 2 for
            the noun.

Check an actor pushing something to (this is the can't push vertically rule):
    if the second noun is up or the second noun is down,
        stop the action with library message pushing it to action number 3 for
            the noun.

Check an actor pushing something to (this is the standard pushing in directions rule):
    convert to special going-with-push action.

Check an actor pushing something to (this is the block pushing in directions rule):
    stop the action with library message pushing it to action number 1 for
        the noun.
```

§131. Squeezing.

```
Squeezing is an action applying to one thing.
The Squeezing action translates into I6 as "Squeeze".

The specification of the squeezing action is "Squeezing is an action which
can conveniently vary from squeezing something hand-held, like a washing-up
liquid bottle, right up to squeezing a pillar in a bear hug.

In the Standard Rules there are no carry out rules for this action because
nothing in the standard Inform world model which reacts to it. The action
is provided for authors to hang more interesting behaviour onto for special
cases. A mildly fruity message is produced to players who attempt to
squeeze people, which is blocked by a check squeezing rule."
```

§132. Check.

```
Check an actor squeezing (this is the innuendo about squeezing people rule):
    if the noun is a person,
        stop the action with library message squeezing action number 1 for
            the noun.
```

§133. Report.

```
Report an actor squeezing (this is the report squeezing rule):
    if the actor is the player, issue library message squeezing action number 2
        for the noun;
    otherwise issue actor-based library message squeezing action number 3 for the noun.
```

§134. Saying yes.

```
Section SR4/8 - Standard actions which always do nothing unless rules intervene

Saying yes is an action with past participle said and applying to nothing.
The Saying yes action translates into I6 as "Yes".

The specification of the saying yes action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§135. Check.

```
Check an actor saying yes (this is the block saying yes rule):
    stop the action with library message saying yes action number 1.
```

§136. Saying no.

```
Saying no is an action with past participle said and applying to nothing.
The Saying no action translates into I6 as "No".

The specification of the saying no action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§137. Check.

```
Check an actor saying no (this is the block saying no rule):
    stop the action with library message saying no action number 1.
```

§138. Burning.

```
Burning is an action applying to one thing.
The Burning action translates into I6 as "Burn".

The specification of the burning action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§139. Check.

```
Check an actor burning (this is the block burning rule):
    stop the action with library message burning action number 1.
```

§140. Waking up.

```
Waking up is an action with past participle woken and applying to nothing.
The Waking up action translates into I6 as "Wake".

The specification of the waking up action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§141. Check.

```
Check an actor waking up (this is the block waking up rule):
    stop the action with library message waking up action number 1.
```

§142. Thinking.

```
Thinking is an action past participle thought and applying to nothing.
The Thinking action translates into I6 as "Think".

The specification of the thinking action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§143. Check.

```
Check an actor thinking (this is the block thinking rule):
    stop the action with library message thinking action number 1.
```

§144. Smelling.

```
Smelling is an action applying to one thing.
The Smelling action translates into I6 as "Smell".

The specification of the smelling action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§145. Check.

```
Check an actor smelling (this is the block smelling rule):
    stop the action with library message smelling action number 1 for the noun.
```

§146. Listening to.

```
Listening to is an action applying to one thing.
The Listening to action translates into I6 as "Listen".

The specification of the listening to action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§147. Check.

```
Check an actor listening (this is the block listening rule):
    stop the action with library message listening to action number 1 for the noun.
```

§148. Tasting.

```
Tasting is an action applying to one thing.
The Tasting action translates into I6 as "Taste".

The specification of the tasting action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§149. Check.

```
Check an actor tasting (this is the block tasting rule):
    stop the action with library message tasting action number 1 for the noun.
```

§150. Cutting.

```
Cutting is an action with past participle cut and applying to one thing.
The Cutting action translates into I6 as "Cut".

The specification of the cutting action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§151. Check.

```
Check an actor cutting (this is the block cutting rule):
    stop the action with library message cutting action number 1 for the noun.
```

§152. Jumping.

```
Jumping is an action applying to nothing.
The Jumping action translates into I6 as "Jump".

The specification of the jumping action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§153. Check.

```
Check an actor jumping (this is the block jumping rule):
    stop the action with library message jumping action number 1.
```

§154. Tying it to.

```
Tying it to is an action with past participle tied, and applying to two things.
The Tying it to action translates into I6 as "Tie".

The specification of the tying it to action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§155. Check.

```
Check an actor tying something to (this is the block tying rule):
    stop the action with library message tying it to action number 1 for the noun.
```

§156. Drinking.

```
Drinking is an action with past participle drunk, and applying to one thing.
The Drinking action translates into I6 as "Drink".

The specification of the drinking action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§157. Check.

```
Check an actor drinking (this is the block drinking rule):
    stop the action with library message drinking action number 1 for the noun.
```

§158. Saying sorry.

```
Saying sorry is an action with past participle said and applying to nothing.
The Saying sorry action translates into I6 as "Sorry".

The specification of the saying sorry action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§159. Check.

```
Check an actor saying sorry (this is the block saying sorry rule):
    stop the action with library message saying sorry action number 1.
```

§160. Swearing obscenely.

```
Swearing obscenely is an action censored, with past participle sworn, and applying to nothing.
The Swearing obscenely action translates into I6 as "Strong".

The specification of the swearing obscenely action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§161. Check.

```
Check an actor swearing obscenely (this is the block swearing obscenely rule):
    stop the action with library message swearing obscenely action number 1.
```

§162. Swearing mildly.

```
Swearing mildly is an action censored, with past participle sworn, and applying to nothing.
The Swearing mildly action translates into I6 as "Mild".

The specification of the swearing mildly action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§163. Check.

```
Check an actor swearing mildly (this is the block swearing mildly rule):
    stop the action with library message swearing mildly action number 1.
```

§164. Swinging.

```
Swinging is an action past participle swung and applying to one thing.
The Swinging action translates into I6 as "Swing".

The specification of the swinging action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§165. Check.

```
Check an actor swinging (this is the block swinging rule):
    stop the action with library message swinging action number 1 for the noun.
```

§166. Rubbing.

```
Rubbing is an action applying to one thing.
The Rubbing action translates into I6 as "Rub".

The specification of the rubbing action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§167. Check.

```
Check an actor rubbing (this is the block rubbing rule):
    stop the action with library message rubbing action number 1 for the noun.
```

§168. Setting it to.

```
Setting it to is an action with past participle set, applying to one thing and one topic.
The Setting it to action translates into I6 as "SetTo".

The specification of the setting it to action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§169. Check.

```
Check an actor setting something to (this is the block setting it to rule):
    stop the action with library message setting it to action number 1 for the noun.
```

§170. Waving hands.

```
Waving hands is an action applying to nothing.
The Waving hands action translates into I6 as "WaveHands".

The specification of the waving hands action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§171. Check.

```
Check an actor waving hands (this is the block waving hands rule):
    stop the action with library message waving hands action number 1.
```

§172. Buying.

```
Buying is an action with past participle bought, and applying to one thing.
The Buying action translates into I6 as "Buy".

The specification of the buying action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§173. Check.

```
Check an actor buying (this is the block buying rule):
    stop the action with library message buying action number 1 for the noun.
```

§174. Singing.

```
Singing is an action with past participle sung and applying to nothing.
The Singing action translates into I6 as "Sing".

The specification of the singing action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§175. Check.

```
Check an actor singing (this is the block singing rule):
    stop the action with library message singing action number 1.
```

§176. Climbing.

```
Climbing is an action applying to one thing.
The Climbing action translates into I6 as "Climb".

The specification of the climbing action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§177. Check.

```
Check an actor climbing (this is the block climbing rule):
    stop the action with library message climbing action number 1 for the noun.
```

§178. Sleeping.

```
Sleeping is an action past participle slept and applying to nothing.
The Sleeping action translates into I6 as "Sleep".

The specification of the sleeping action is
"The Standard Rules define this action in only a minimal way, blocking it
with a check rule which stops it in all cases. It exists so that before
or instead rules can be written to make it do interesting things in special
cases. (Or to reconstruct the action as something more substantial, unlist
the block rule and supply carry out and report rules, together perhaps
with some further check rules.)"
```

§179. Check.

```
Check an actor sleeping (this is the block sleeping rule):
    stop the action with library message sleeping action number 1.
```

§**180. Out of world actions.** We start with a brace of actions which control the (virtual) hardware of the virtual machine: restore, save, quit, restart, verify, and transcript on and off. All of these are implemented at the I6 level where, in fact, they are delegated quickly to assembly language instructions for whichever is the current VM: so these are close to the metal, as they say.

```
Section SR4/9 - Standard actions which happen out of world

Quitting the game is an action out of world and applying to nothing.
The quitting the game action translates into I6 as "Quit".

The quit the game rule is listed in the carry out quitting the game rulebook.
The quit the game rule translates into I6 as "QUIT_THE_GAME_R".

Saving the game is an action out of world and applying to nothing.
The saving the game action translates into I6 as "Save".

The save the game rule is listed in the carry out saving the game rulebook.
The save the game rule translates into I6 as "SAVE_THE_GAME_R".

Restoring the game is an action out of world and applying to nothing.
The restoring the game action translates into I6 as "Restore".

The restore the game rule is listed in the carry out restoring the game rulebook.
The restore the game rule translates into I6 as "RESTORE_THE_GAME_R".

Restarting the game is an action out of world and applying to nothing.
The restarting the game action translates into I6 as "Restart".

The restart the game rule is listed in the carry out restarting the game rulebook.
The restart the game rule translates into I6 as "RESTART_THE_GAME_R".

Verifying the story file is an action out of world, with past participle verified
    and applying to nothing.
The verifying the story file action translates into I6 as "Verify".

The verify the story file rule is listed in the carry out verifying the story file rulebook.
The verify the story file rule translates into I6 as "VERIFY_THE_STORY_FILE_R".

Switching the story transcript on is an action out of world and applying to nothing.
The switching the story transcript on action translates into I6 as "ScriptOn".

The switch the story transcript on rule is listed in the carry out switching the story
    transcript on rulebook.
The switch the story transcript on rule translates into I6 as "SWITCH_TRANSCRIPT_ON_R".

Switching the story transcript off is an action out of world and applying to nothing.
The switching the story transcript off action translates into I6 as "ScriptOff".

The switch the story transcript off rule is listed in the carry out switching the story
    transcript off rulebook.
The switch the story transcript off rule translates into I6 as "SWITCH_TRANSCRIPT_OFF_R".
```

§**181.** The VERSION command is not quite so close to the metal – it is implemented in I6, at the end of the day – but it does involve reading the bytes of the story file header, so it needs to take quite different forms for the different formats being compiled to.

```
Requesting the story file version is an action out of world and applying to nothing.
The requesting the story file version action translates into I6 as "Version".

The announce the story file version rule is listed in the carry out requesting the story
    file version rulebook.
The announce the story file version rule translates into I6 as "ANNOUNCE_STORY_FILE_VERSION_R".
```

§**182.** There's really no very good reason why we provide the out-of-world command SCORE but not (say) TIME, or any one of dozens of other traditional what's-my-status commands: DIAGNOSE, say, or PLACES. But we are conservative on this; it's easy for users or extensions to provide these verbs if they want them, and they are not always appropriate for every project. Even SCORE is questionable, but its removal would be a gesture too far.

```
Requesting the score is an action out of world and applying to nothing.
The requesting the score action translates into I6 as "Score".

The announce the score rule is listed in the carry out requesting the score rulebook.
The announce the score rule translates into I6 as "ANNOUNCE_SCORE_R".
```

§**183.** It's perhaps clumsy to have three actions for switching the style of room description, but this accords with I6 custom (and Infocom's, for that matter), and does no harm.

```
Preferring abbreviated room descriptions is an action out of world and applying to nothing.
The preferring abbreviated room descriptions action translates into I6 as "LMode3".

The prefer abbreviated room descriptions rule is listed in the carry out preferring
    abbreviated room descriptions rulebook.
The prefer abbreviated room descriptions rule translates into I6 as "PREFER_ABBREVIATED_R".

The standard report preferring abbreviated room descriptions rule is listed in the
    report preferring abbreviated room descriptions rulebook.
The standard report preferring abbreviated room descriptions rule translates into
    I6 as "REP_PREFER_ABBREVIATED_R".

Preferring unabbreviated room descriptions is an action out of world and applying to nothing.
The preferring unabbreviated room descriptions action translates into I6 as "LMode2".

The prefer unabbreviated room descriptions rule is listed in the carry out preferring
    unabbreviated room descriptions rulebook.
The prefer unabbreviated room descriptions rule translates into I6 as "PREFER_UNABBREVIATED_R".

The standard report preferring unabbreviated room descriptions rule is listed in the
    report preferring unabbreviated room descriptions rulebook.
The standard report preferring unabbreviated room descriptions rule translates into
    I6 as "REP_PREFER_UNABBREVIATED_R".

Preferring sometimes abbreviated room descriptions is an action out of world and
    applying to nothing.
The preferring sometimes abbreviated room descriptions action translates into I6 as "LMode1".

The prefer sometimes abbreviated room descriptions rule is listed in the carry out
    preferring sometimes abbreviated room descriptions rulebook.
The prefer sometimes abbreviated room descriptions rule translates into I6 as
    "PREFER_SOMETIMES_ABBREVIATED_R".

The standard report preferring sometimes abbreviated room descriptions rule is listed
    in the report preferring sometimes abbreviated room descriptions rulebook.
The standard report preferring sometimes abbreviated room descriptions rule translates
    into I6 as "REP_PREFER_SOMETIMES_ABBR_R".
```

§**184.** Similarly, two different actions handle "notify" and "notify off".

```
Switching score notification on is an action out of world and applying to nothing.
The switching score notification on action translates into I6 as "NotifyOn".

The switch score notification on rule is listed in the carry out switching score
    notification on rulebook.
The switch score notification on rule translates into I6 as "SWITCH_SCORE_NOTIFY_ON_R".

The standard report switching score notification on rule is listed in the report
    switching score notification on rulebook.
The standard report switching score notification on rule translates into
    I6 as "REP_SWITCH_NOTIFY_ON_R".

Switching score notification off is an action out of world and applying to nothing.
The switching score notification off action translates into I6 as "NotifyOff".

The switch score notification off rule is listed in the carry out switching score
    notification off rulebook.
The switch score notification off rule translates into I6 as "SWITCH_SCORE_NOTIFY_OFF_R".

The standard report switching score notification off rule is listed in the report
    switching score notification off rulebook.
The standard report switching score notification off rule translates into
    I6 as "REP_SWITCH_NOTIFY_OFF_R".
```

§**185.** Lastly, the "pronouns" verb, which is perhaps more often used by people debugging the I6 parser than by actual players.

```
Requesting the pronoun meanings is an action out of world and applying to nothing.
The requesting the pronoun meanings action translates into I6 as "Pronouns".

The announce the pronoun meanings rule is listed in the carry out requesting the
    pronoun meanings rulebook.
The announce the pronoun meanings rule translates into I6 as "ANNOUNCE_PRONOUN_MEANINGS_R".
```

§**186. Miscellaneous Grammar Tokens.** There's only one of these, at present.

```
The understand token a time period translates into I6 as "RELATIVE_TIME_TOKEN".
```

§187. Grammar.

```
Section SR4/10 - Grammar

Understand "take [things]" as taking.
Understand "take off [something]" as taking off.
Understand "take [things inside] from [something]" as removing it from.
Understand "take [things inside] off [something]" as removing it from.
Understand "take inventory" as taking inventory.
Understand the commands "carry" and "hold" as "take".

Understand "get out/off/up" as exiting.
Understand "get [things]" as taking.
Understand "get in/into/on/onto [something]" as entering.
Understand "get off [something]" as getting off.
Understand "get [things inside] from [something]" as removing it from.

Understand "pick up [things]" or "pick [things] up" as taking.

Understand "stand" or "stand up" as exiting.
Understand "stand on [something]" as entering.

Understand "remove [something preferably held]" as taking off.
Understand "remove [things inside] from [something]" as removing it from.

Understand "shed [something preferably held]" as taking off.
Understand the commands "doff" and "disrobe" as "shed".

Understand "wear [something preferably held]" as wearing.
Understand the command "don" as "wear".

Understand "put [other things] in/inside/into [something]" as inserting it into.
Understand "put [other things] on/onto [something]" as putting it on.
Understand "put on [something preferably held]" as wearing.
Understand "put down [things preferably held]" or "put [things preferably held] down" as dropping.

Understand "insert [other things] in/into [something]" as inserting it into.

Understand "drop [things preferably held]" as dropping.
Understand "drop [other things] in/into/down [something]" as inserting it into.
Understand "drop [other things] on/onto [something]" as putting it on.
Understand "drop [something preferably held] at/against/on/onto [something]" as throwing it at.
Understand the commands "throw" and "discard" as "drop".

Understand "give [something preferably held] to [someone]" as giving it to.
Understand "give [someone] [something preferably held]" as giving it to (with nouns reversed).
Understand the commands "pay" and "offer" and "feed" as "give".

Understand "show [someone] [something preferably held]" as showing it to (with nouns reversed).
Understand "show [something preferably held] to [someone]" as showing it to.
Understand the commands "present" and "display" as "show".

Understand "go" as going.
Understand "go [direction]" as going.
Understand "go [something]" as entering.
Understand "go into/in/inside/through [something]" as entering.
Understand the commands "walk" and "run" as "go".

Understand "inventory" as taking inventory.
Understand the commands "i" and "inv" as "inventory".

Understand "look" as looking.
Understand "look at [something]" as examining.
Understand "look inside/in/into/through [something]" as searching.
Understand "look under [something]" as looking under.
```

```
Understand "look up [text] in [something]" as consulting it about (with nouns reversed).
Understand the command "l" as "look".

Understand "consult [something] on/about [text]" as consulting it about.

Understand "open [something]" as opening.
Understand "open [something] with [something preferably held]" as unlocking it with.
Understand the commands "unwrap", "uncover" as "open".

Understand "close [something]" as closing.
Understand "close up [something]" as closing.
Understand "close off [something]" as switching off.
Understand the commands "shut" and "cover" as "close".

Understand "enter [something]" as entering.
Understand the command "cross" as "enter".

Understand "sit on top of [something]" as entering.
Understand "sit on/in/inside [something]" as entering.

Understand "exit" as exiting.
Understand the commands "leave" and "out" as "exit".

Understand "examine [something]" as examining.
Understand the commands "x", "watch", "describe" and "check" as "examine".

Understand "read [something]" as examining.
Understand "read about [text] in [something]" as consulting it about (with nouns reversed).
Understand "read [text] in [something]" as consulting it about (with nouns reversed).

Understand "yes" as saying yes.
Understand the command "y" as "yes".

Understand "no" as saying no.

Understand "sorry" as saying sorry.

Understand "bother" as swearing mildly.
```

...and so on...

```
Understand "search [something]" as searching.

Understand "wave" as waving hands.

Understand "wave [something]" as waving.

Understand "set [something] to [text]" as setting it to.
Understand the command "adjust" as "set".

Understand "pull [something]" as pulling.
Understand the command "drag" as "pull".

Understand "push [something]" as pushing.
Understand "push [something] [direction]" or "push [something] to [direction]" as pushing it to.
Understand the commands "move", "shift", "clear" and "press" as "push".

Understand "turn [something]" as turning.
Understand "turn [something] on" or "turn on [something]" as switching on.
Understand "turn [something] off" or "turn off [something]" as switching off.
Understand the commands "rotate", "twist", "unscrew" and "screw" as "turn".

Understand "switch [something]" or "switch on [something]" or "switch [something] on" as
    switching on.
Understand "switch [something] off" or "switch off [something]" as switching off.

Understand "lock [something] with [something preferably held]" as locking it with.

Understand "unlock [something] with [something preferably held]" as unlocking it with.

Understand "attack [something]" as attacking.
```

```
Understand the commands "break", "smash", "hit", "fight", "torture", "wreck", "crack", "destroy",
    "murder", "kill", "punch" and "thump" as "attack".

Understand "wait" as waiting.
Understand the command "z" as "wait".

Understand "answer [text] to [someone]" as answering it that (with nouns reversed).
Understand the commands "say", "shout" and "speak" as "answer".

Understand "tell [someone] about [text]" as telling it about.

Understand "ask [someone] about [text]" as asking it about.
Understand "ask [someone] for [something]" as asking it for.

Understand "eat [something preferably held]" as eating.

Understand "sleep" as sleeping.
Understand the command "nap" as "sleep".

Understand "sing" as singing.

Understand "climb [something]" or "climb up/over [something]" as climbing.
Understand the command "scale" as "climb".

Understand "buy [something]" as buying.
Understand the command "purchase" as "buy".

Understand "squeeze [something]" as squeezing.
Understand the command "squash" as "squeeze".

Understand "swing [something]" or "swing on [something]" as swinging.

Understand "wake" or "wake up" as waking up.
Understand "wake [someone]" or "wake [someone] up" or "wake up [someone]" as waking.
Understand the commands "awake" and "awaken" as "wake".

Understand "kiss [someone]" as kissing.
Understand the commands "embrace" and "hug" as "kiss".

Understand "think" as thinking.

Understand "smell" as smelling.
Understand "smell [something]" as smelling.
Understand the command "sniff" as "smell".

Understand "listen" as listening.
Understand "hear [something]" as listening.
Understand "listen to [something]" as listening.

Understand "taste [something]" as tasting.

Understand "touch [something]" as touching.
Understand the command "feel" as "touch".

Understand "rub [something]" as rubbing.
Understand the commands "shine", "polish", "sweep", "clean", "dust", "wipe" and "scrub" as "rub".

Understand "tie [something] to [something]" as tying it to.
Understand the commands "attach", "fix" and "fasten" as "tie".

Understand "burn [something]" as burning.
Understand the command "light" as "burn".

Understand "drink [something]" as drinking.
Understand the commands "swallow" and "sip" as "drink".

Understand "cut [something]" as cutting.
Understand the commands "slice", "prune" and "chop" as "cut".

Understand "jump" as jumping.
Understand the commands "skip" and "hop" as "jump".
```

```
Understand "score" as requesting the score.
Understand "quit" or "q" as quitting the game.
Understand "save" as saving the game.
Understand "restart" as restarting the game.
Understand "restore" as restoring the game.
Understand "verify" as verifying the story file.
Understand "version" as requesting the story file version.
Understand "script" or "script on" or "transcript" or "transcript on" as switching the story
    transcript on.
Understand "script off" or "transcript off" as switching the story transcript off.
Understand "superbrief" or "short" as preferring abbreviated room descriptions.
Understand "verbose" or "long" as preferring unabbreviated room descriptions.
Understand "brief" or "normal" as preferring sometimes abbreviated room descriptions.
Understand "nouns" or "pronouns" as requesting the pronoun meanings.
Understand "notify" or "notify on" as switching score notification on.
Understand "notify off" as switching score notification off.
```

SR5 - Phrase Definitions A/sr5

Purpose

The phrases making up the Inform language, and in terms of which all other phrases and rules are defined; and the final sign-off of the Standard Rules extension, including its minimal documentation.

---

§**1.** Our last task is to create the phrases: more or less all of them, but that does need a little qualification. NI has no phrase definitions built in, but it does contain assumptions about how "say ...", "repeat ...", "let ...", "otherwise ..." and "end ..." will behave when defined: we would not be allowed to call these something else, or redefine them in fundamentally different ways. Apart from that, we are more or less free.

Most of these phrases are defined in terms of I6 code, using the `(-` and `-)` notation – it would be too cumbersome to use the "... translates into I6 as ..." verb for this, too. The fact that phrases are not so much translated as transliterated was one source of early criticism of Inform 7. Phrases appeared to have very simplistic definitions, with the natural language simply being a verbose description of obviously equivalent I6 code. However, the simplicity is misleading, because the definitions below tend to conceal where the complexity of the translation process suddenly increases. If the preamble includes "(c - condition)", and the definition includes the expansion `{c}`, then the text forming c is translated in a way much more profound than any simple substitution process could describe. Type-checking also complicates the code produced below, since NI automatically generates the code needed to perform run-time type checking at any point where doubt remains as to the phrase definition which must be used.

§**2. Say phrases.** We begin with saying phrases: the very first phrase to exist is the one printing a single piece of static text, which seems only appropriate for an IF system. But in fact this is only one of a family of similar phrases. For every kind of value K which can be printed out, we have to define "say (something - K)": this first phrase is that definition for the case where K is "text". (Well: strictly speaking, it's only true that we define this for each atomic K and also for each KOV constructor. Thus "list of K_1" and "list of K_2" are each said by the same phrase, "say (X - list of values)", which is viable since lists store their types at run-time. This ensures that the number of "say (something - K)" doesn't skyrocket with all of the possibilities for lists, lists of lists and so on. And similarly we only make one "say (X - object)", not a whole pile of definitions for "say (X - room)", "say (X - direction)" and so on for each other kind.)

We have this plethora of alternative "say (something - K)" definitions in order to give the type-checking machinery options as to which to use on any given value. But the fact that all these alternative definitions exist is not altogether obvious, because they are hidden in no fewer than three ways:

(1) Very few of them are defined below, because most are defined instead by the data type interpreter, either using definitions tabulated in the `Types.i6t` template file (for built-in KOVS like "table" or "rule"), or when new KOVS are created (when the user creates a unit or a new enumerated KOV).

(2) The Phrasebook page of the index covers all of them with the generic entry: say "[*a value of some sort*]".

(3) Invocation lists built during parsing, which normally hold all possible interpretations of text as a phrase, are optimised a little so that in clear-cut cases (which is almost all cases, in practice) they will only ever contain one "say (something - K)" possibility. For instance, if "say 23" is parsed, the invocation list will not bother to store "say (something - text)" as one of the possibilities, because manifestly 23 is not a piece of text.

Anyway, here are three of the four cases of "say (something - K)" to be created in the Standard Rules rather than elsewhere.

```
Part SR5 - Phrasebook

Section SR5/1/1 - Saying - Values

To say (something - text)
    (documented at ph_say):
    (- print (PrintText) {something}; -).
To say (something - number):
    (- print (say__n={something}); -).
```

§**3.** Note that emitting a Unicode character requires different code on the Z-machine to Glulx; we have to handle this within I6 conditional compilation blocks because neither syntax will compile when I6 is compiling for the other VM. It would be tidier to abstract this with a function call, but it would cost a function call.

```
To say (ch - unicode-character) -- running on:
    (- #ifdef TARGET_ZCODE; @print_unicode {ch};
    #ifnot; if (unicode_gestalt_ok) glk_put_char_uni({ch}); else print "?"; #endif; -).
```

§**4.** Three little grace-notes for printing values: we can have numbers or times of day "in words", rather than given as digits, and we can produce an optional "s" where a number not equal to 1 has recently been printed. This is how "You see [X] balloon[s]." is handled: the printing of the value X sets the I6 variable `say__n` as a side-effect (see definition above) and the routine handling "[s]" looks at this variable to see whether to print an "s" or not.

```
To say (something - number) in words
    (documented at ph_sayn):
    (- print (number) say__n=({something}); -).
To say (something - time) in words:
    (- print (PrintTimeOfDayEnglish) {something}; -).
To say s
    (documented at ph_sayn):
    (- STextSubstitution(); -).
```

§**5.** Now we come to the fourth and last of the "say (something - *K*)" definitions in the SR, followed by six close variations. Note that say phrases are case sensitive on the first word, so that "to say a something" and "to say A something" are different.

A curiosity of the original I6 design, arising I think mostly from the need to save property memory in *Curses* (1993), the work of IF for which Inform 1 had been created, is that it lacks the `print (A) ...` syntax to match the other forms. The omission is made good by using a routine in the I6 library instead.

```
Section SR5/1/2 - Saying - Names with articles

To say (something - object):
    (- print (name) {something}; -).
To say a (something - object)
    (documented at ph_saya):
    (- print (a) {something}; -).
To say an (something - object)
    (documented at ph_saya):
    (- print (a) {something}; -).
To say A (something - object):
    (- CIndefArt({something}); -).
To say An (something - object):
    (- CIndefArt({something}); -).
To say the (something - object):
    (- print (the) {something}; -).
To say The (something - object):
    (- print (The) {something}; -).
```

§**6.** Now for "[if ...]", which expands into a rather assembly-language-like usage of `jump` statements, I6's form of goto. For instance, the text "[if the score is 10]It's ten![otherwise]It's not ten, alas." compiles thus:

```
if (~~(score == 10)) jump L_Say3;
    ...
jump L_SayX2; .L_Say3;
    ...
.L_Say4; .L_SayX2;
```

Though labels actually have local namespaces in I6 routines, we use globally unique labels throughout the whole program: compiling the same phrase again would involve say labels 5 and 6 and "say exit" label 3. This example text demonstrates the reason we `jump` about, rather than making use of `if... else...` and bracing groups of statements: it is legal in I7 either to conclude with or to omit the "[end if]". (If statements in I6 compile to jump instructions in any event, and on our virtual machines there is no speed penalty for branches.) We also need the same definitions to accommodate what amounts to a switch statement. The trickier text "[if the score is 10]It's ten![otherwise if the score is 8]It's eight?[otherwise]It's not ten, alas." comes out as:

```
if (~~(score == 10)) jump L_Say5;
    ...
jump L_SayX3; .L_Say5; if (~~(score == 8)) jump L_Say6;
    ...
jump L_SayX3; .L_Say6;
    ...
.L_Say7; .L_SayX3;
```

In either form of the construct, control passes into at most one of the pieces of text. The terminal labels (the two on the final line) are automatically generated; often – when there is a simple "otherwise" or "end if" to conclude the construct – they are not needed, but labels are quick to process in I6, are soon discarded from I6's memory when not needed any more, and compile no code.

We assume in each case that the next say label number to be free is always the start of the next block, and that the next say exit label number is always the one at the end of the current construct. This is true because NI does not allow "say if" to be nested.

(The use of `{-erase}` below only tidies up the white space to set out the compiled I6 code neatly, and has no effect on the eventual story file.)

```
Section SR5/1/3 - Saying - Say if and otherwise

To say if (c - condition)
    (documented at ph_sayif): (- {-erase}
    if (~~({c})) jump {-next-label:Say};
        -).
To say unless (c - condition): (- {-erase}
    if ({c}) jump {-next-label:Say};
        -).
To say end if: (- {-erase}
    .{-label:Say}; .{-label:SayX};
        -).
To say end unless: (- {-erase}
    .{-label:Say}; .{-label:SayX};
        -).
To say otherwise/else if (c - condition): (- {-erase}
    jump {-next-label:SayX}; .{-label:Say}; if (~~({c})) jump {-next-label:Say};
        -).
To say otherwise/else unless (c - condition): (- {-erase}
    jump {-next-label:SayX}; .{-label:Say}; if ({c}) jump {-next-label:Say};
        -).
To say otherwise: (- {-erase}
    jump {-next-label:SayX}; .{-label:Say};
        -).
To say else: (- {-erase}
    jump {-next-label:SayX}; .{-label:Say};
        -).
```

§**7.** The other control structure: the random variations form of saying. This part of the Standard Rules was in effect contributed by the community: it reimplements a form of Jon Ingold's former extension Text Variations, which itself built on code going back to the days of I6.

The head phrase here has one of the most complicated definitions in the SR, but is actually documented fairly explicitly in the *Extensions* chapter of *Writing with Inform*, so we won't repeat all that here. Essentially it uses its own allocated cell of storage in an array to remember a state between uses, and compiles as a switch statement based on the current state.

```
Section SR5/1/4 - Saying - Say one of

To say one of -- beginning say_one_of (documented at ph_sayoneof):
    (- {-allocate-storage:say_one_of}I7_ST_say_one_of-->{-counter:say_one_of} =
    {-final-segment-marker}(I7_ST_say_one_of-->{-counter:say_one_of}, {-segment-count});
    switch((I7_ST_say_one_of-->{-advance-counter:say_one_of})%({-segment-count}+1)-1) {-open-brace}
        0: -).
To say or -- continuing say_one_of:
    (- @nop; {-segment-count}: -).
To say purely at random -- ending say_one_of with marker I7_SOO_PAR:
    (- {-close-brace} -).
To say at random -- ending say_one_of with marker I7_SOO_RAN:
```

```
    (- {-close-brace} -).
To say sticky random -- ending say_one_of with marker I7_SOO_STI:
    (- {-close-brace} -).
To say as decreasingly likely outcomes -- ending say_one_of with marker I7_SOO_TAP:
    (- {-close-brace} -).
To say in random order -- ending say_one_of with marker I7_SOO_SHU:
    (- {-close-brace} -).
To say cycling -- ending say_one_of with marker I7_SOO_CYC:
    (- {-close-brace} -).
To say stopping -- ending say_one_of with marker I7_SOO_STOP:
    (- {-close-brace} -).
```

§**8.** For an explanation of the paragraph breaking algorithm, see the template file "Printing.i6t".

```
Section SR5/1/5 - Saying - Paragraph control

To say line break -- running on
    (documented at ph_lbreak):
    (- new_line; -).
To say no line break -- running on: do nothing.
To say conditional paragraph break -- running on:
    (- DivideParagraphPoint(); -).
To say command clarification break -- running on:
    (- CommandClarificationBreak(); -).
To say paragraph break -- running on:
    (- DivideParagraphPoint(); new_line; -).
To say run paragraph on -- running on:
    (- RunParagraphOn(); -).
To say run paragraph on with special look spacing -- running on:
    (- SpecialLookSpacingBreak(); -).
To decide if a paragraph break is pending:
    (- (say__p) -).
```

§**9.** Now some text substitutions which are the equivalent of escape characters. (In double-quoted I6 text, the notation for a literal quotation mark is a tilde ~.)

```
Section SR5/1/6 - Saying - Special characters

To say bracket -- running on:
    (- print "["; -).
To say close bracket -- running on:
    (- print "]"; -).
To say apostrophe/' -- running on:
    (- print "'"; -).
To say quotation mark -- running on:
    (- print "~"; -).
```

§**10.** Now some visual effects, which may or may not be rendered the way the user hopes: that's partly up to the virtual machine, unfortunately.

```
Section SR5/1/7 - Saying - Fonts and visual effects

To say bold type -- running on
    (documented at ph_types):
    (- style bold; -).
To say italic type -- running on:
    (- style underline; -).
To say roman type -- running on:
    (- style roman; -).
To say fixed letter spacing -- running on:
    (- font off; -).
To say variable letter spacing -- running on:
    (- font on; -).
To display the boxed quotation (Q - boxed-quotation)
    (documented at ph_boxed):
    (- DisplayBoxedQuotation({Q}); -).
```

§**11.** And now some oddball special texts which must sometimes be said.

```
Section SR5/1/8 - Saying - Some built-in texts

To say the/-- banner text
    (documented at act_banner):
    (- Banner(); -).
To say the/-- list of extension credits
    (documented at ph_extcr):
    (- ShowExtensionVersions(); -).
To say the/-- complete list of extension credits:
    (- ShowFullExtensionVersions(); -).
To say the/-- player's surroundings
    (documented at ph_surrounds):
    (- SL_Location(); -).
```

§**12. Using the list-writer.** The I7 list-writer resembles the old I6 library one, but has been reimplemented in a more general way: see the template file "ListWriter.i6t". The following is the main routine for listing:

```
Section SR5/1/9 - Saying - Saying lists of things

To list the contents of (O - an object),
    with newlines,
    indented,
    giving inventory information,
    as a sentence,
    including contents,
    including all contents,
    tersely,
    giving brief inventory information,
    using the definite article,
    listing marked items only,
    prefacing with is/are,
```

```
    not listing concealed items,
    suppressing all articles
    and/or with extra indentation
    (documented at ph_list):
    (- WriteListFrom(child({O}), {phrase options}); -).
To say contents of (O - an object):
    list the contents of O, as a sentence.
To say the contents of (O - an object):
    list the contents of O, as a sentence, using the definite article.
```

§**13. Text substitutions using the list-writer.** These all look (and are) repetitive. We want to avoid passing a description value to some routine, because that's tricky if the description needs to refer to a value local to the current stack frame. (There are ways round that, but it minimises nuisance to avoid the need.) So we mark out the set of objects matching by giving them, and only them, the `workflag2` attribute.

```
To say a list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT);
        @pull subst__v; -).
To say A list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+CFIRSTART_BIT);
        @pull subst__v; -).
To say list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+NOARTICLE_BIT);
        @pull subst__v; -).
To say the list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+DEFART_BIT);
        @pull subst__v; -).
To say The list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+DEFART_BIT+CFIRSTART_BIT);
        @pull subst__v; -).
To say is-are a list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+ISARE_BIT);
        @pull subst__v; -).
To say is-are list of (OS - description):
```

```
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+ISARE_BIT+NOARTICLE_BIT);
        @pull subst__v; -).
To say is-are the list of (OS - description):
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+DEFART_BIT+ISARE_BIT);
        @pull subst__v; -).
To say a list of (OS - description) including contents:
    (- @push subst__v;
        objectloop (subst__v ofclass Object) if ({-bind-variable:OS})
        give subst__v workflag2; else give subst__v ~workflag2;
        WriteListOfMarkedObjects(ENGLISH_BIT+RECURSE_BIT+PARTINV_BIT+
            TERSE_BIT+CONCEAL_BIT);
        @pull subst__v; -).
```

§**14. Grouping in the list-writer.** See the specifications of `list_together` and `c_style` in the DM4, which are still broadly accurate.

```
Section SR5/1/10 - Saying - Group in and omit from lists

To group (OS - description) together
    (documented at ph_group):
    (- @push subst__v;
        objectloop (subst__v provides list_together) if ({-bind-variable:OS})
        subst__v.list_together = {-list-together};
        @pull subst__v; -).
To group (OS - description) together giving articles:
    (- @push subst__v;
        objectloop (subst__v provides list_together) if ({-bind-variable:OS})
        subst__v.list_together = {-articled-list-together};
        @pull subst__v; -).
To group (OS - description) together as (T - text):
    (- @push subst__v;
        objectloop (subst__v provides list_together) if ({-bind-variable:OS})
        subst__v.list_together = {T};
        @pull subst__v; -).
To omit contents in listing
    (documented at ph_omit):
    (- c_style = c_style &~ (RECURSE_BIT+FULLINV_BIT+PARTINV_BIT); -).
```

§**15. Lists written but not by the list-writer.** These are lists in the sense of the "list of" kind of value constructor, and they might contain any values, not just objects. They're printed by code in "Lists.i6t".

```
Section SR5/1/11 - Saying - Lists of values

To say (L - a list of values) in brace notation
    (documented at ph_saylv):
    (- LIST_OF_TY_Say({-pointer-to:L}, 1); -).
To say (L - a list of objects) with definite articles:
    (- LIST_OF_TY_Say({-pointer-to:L}, 2); -).
To say (L - a list of objects) with indefinite articles:
    (- LIST_OF_TY_Say({-pointer-to:L}, 3); -).
```

§**16. Filtering in the list-writer.** Something of a last resort, which is intentionally not documented. It's needed by the Standard Rules to tidy up an implementation and avoid I6, but is not an ideal trick and may be dropped in later builds. Recursion occurs when the list-writer descends to the contents of, or items supported by, something it lists. Here we can restrict to just those contents, or supportees, matching a description `D`.

```
Section SR5/1/12 - Saying - Filtering contents - Unindexed

To filter list recursion to (D - description):
    (- list_filter_routine = {D}; -).
To unfilter list recursion:
    (- list_filter_routine = 0; -).
```

§**17. Values and data structures.** To begin with, counting the number of items matching a description.

```
Section SR5/2/1 - Values and data structures - Counting

To decide which number is number of (S - description)
    (documented at ph_numof):
    (- {-number-of:S} -).
To decide which number is number of (S - domain-description)
    (documented at ph_numof):
    (- {-number-of:S} -).
```

§**18.** There are eight arithmetic operations, internally numbered 0 to 7, and given verbal forms below. These are handled unusually in the type-checker because they need to be more polymorphic than most phrases: Inform uses dimension-checking to determine the kind of value resulting. (Thus a height times a number is another height, and so on.)

The totalling code (10) is not structly to do with arithmetic in the same way, but it's needed to flag the phrase for the Inform typechecker's special attention.

```
Section SR5/2/2 - Values and data structures - Arithmetic

To decide which number is (X - number) + (Y - number)
    (arithmetic operation 0)
    (documented at ph_plus): (- ({X}+{Y}) -).
To decide which number is (X - number) - (Y - number)
    (arithmetic operation 1):
    (- ({X}-{Y}) -).
To decide which number is (X - number) * (Y - number)
    (arithmetic operation 2):
    (- ({X}*{Y}{-rescale-times}) -).
To decide which number is (X - number) / (Y - number)
    (arithmetic operation 3):
    (- (IntegerDivide({X}{-rescale-divide},{Y})) -).
To decide which number is (X - number) plus (Y - number)
    (arithmetic operation 0):
    (- ({X}+{Y}) -).
To decide which number is (X - number) minus (Y - number)
    (arithmetic operation 1):
    (- ({X}-{Y}) -).
To decide which number is (X - number) times (Y - number)
    (arithmetic operation 2):
    (- ({X}*{Y}{-rescale-times}) -).
To decide which number is (X - number) multiplied by (Y - number)
    (arithmetic operation 2):
    (- ({X}*{Y}{-rescale-times}) -).
To decide which number is (X - number) divided by (Y - number)
    (arithmetic operation 3):
    (- (IntegerDivide({X}{-rescale-divide},{Y})) -).
To decide which number is remainder after dividing (X - number)
    by (Y - number)
    (arithmetic operation 4):
    (- (IntegerRemainder({X},{Y})) -).
To decide which number is (X - number) to the nearest (Y - number)
    (arithmetic operation 5):
    (- (RoundOffTime({X},{Y})) -).
```

```
To decide which number is the square root of (X - number)
    (arithmetic operation 6):
    (- (SquareRoot({X}{-rescale-root})) -).
To decide which number is the cube root of (X - number)
    (arithmetic operation 7):
    (- (CubeRoot({X}{-rescale-cuberoot})) -).
To decide which number is total (p - property) of (S - description)
    (arithmetic operation 11)
    (documented at ph_total):
    (- {-total-of:S} -).
```

§**19.** The following exists only to convert a condition to a value, and is needed because I7 does not silently cast from one to the other in the way that C would.

```
Section SR5/2/3 - Values and data structures - Truth states

To decide what truth state is whether or not (C - condition)
    (documented at ph_wornot):
    (- ({C}) -).
```

§**20.** Random numbers and random items chosen from sets of objects matching a given description ("a random closed door").

```
Section SR5/2/4 - Values and data structures - Randomness

To decide which object is a/-- random (S - description)
    (documented at ph_randobj):
    (- {-random-of:S} -).
To decide which number is a random number from (N - number) to (M - number)
    (documented at ph_random):
    (- (GenerateRandomNumber({N}, {M})) -).
To decide which number is a random number between (N - number) and (M - number):
    (- (GenerateRandomNumber({N}, {M})) -).
To decide whether a random chance of (N - number) in (M - number) succeeds:
    (- (GenerateRandomNumber(1, {M}) <= {N}) -).
To seed the random-number generator with (N - number):
    (- VM_Seed_RNG({N}); -).
To decide which value is a/-- random (S - domain-description)
    (amended kind of value 1):
    (- {-random-of:S} -).
```

§**21.** The "now" phrase is somewhat unclassifiable, and though it doesn't quite belong here, it doesn't quite belong anywhere else either:

```
Section SR5/2/5 - Values and data structures - Changing stored values

To now (cn - now-condition)
    (documented at ph_now):
    (- {cn} -).
```

§**22.** Assignment is probably the most difficult thing the type-checker has to cope with, since "let" has to work when applied to both unknown names (it creates a new variable) and existing ones (kind of value permitting). Moreover, the assignment itself works differently depending on whether the values are pointers to blocks of data on the heap, needing a deep destruction and a deep copy, or are simple values, so that one can simply overwrite the other. All of this makes the "To let" section here only slightly shorter than John Galsworthy's Forsyte novel of the same name:

```
To let (t - nonexisting variable) be (u - word value)
    (assignment operation)
    (documented at ph_let):
    (- {t} = {u}; -).
To let (t - nonexisting variable) be (u - pointer value)
    (assignment operation):
    (- {-pointer-to:t}={-allocate-storage-for:u};BlkValueCopy({-pointer-to:t},{-pointer-to:u}); -).
To let (t - nonexisting variable) be (u - kind of word value)
    (assignment operation):
    (- {t} = {-default-value-for:u}; -).
To let (t - nonexisting variable) be (u - kind of pointer value)
    (assignment operation):
    (- {-pointer-to:t} = {-allocate-storage-for:u}; -).
To let (t - existing variable) be (u - assignable-value)
    (assignment operation):
    (- {-assignment}; -).
```

§**23.** These are not strictly speaking assignments; the value placed in `t` is found by solving the equation `Q`. This does require special typechecking, but of a different kind to that requested by "(assignment operation)".

```
To let (t - existing variable) be given by (Q - equation-name):
    (- {-solve-equation}; -).
To let (t - nonexisting variable) be given by (Q - equation-name):
    (- {-solve-equation}; -).
```

§**24.** There are five sorts of storage in I7 at present: local variables (i.e., "let" and "called" variables, together with parameters in "To..." preambles), global variables, table entries, property values and list entries. Objects are not a form of storage in this sense. The reason we handle "change O to X" specially where O is an object is that it's legal to "change O to open" if O is a container or door, or to "change O to 20kg" if O has a weight, for instance. The meaning then is to do with the transference of a property, not an assignment. This requires careful disambiguation, since O may be, e.g., a global variable whose kind of value is "object".

```
To change (p - property-value) to (w - assignable-value)
    (assignment operation)
    (documented at ph_changev):
    (- {-assignment}; -).
To change (gv - global variable) to (w - assignable-value)
    (assignment operation)
    (documented at ph_change):
    (- {-assignment}; -).
To change (tr - table-reference) to (w - assignable-value)
    (assignment operation):
    (- {-assignment}; -).
To change (le - list-entry) to (w - assignable-value)
```

```
    (assignment operation):
    (- {-assignment}; -).
To change (o - object) to (p - property)
    (assignment operation)
    (documented at ph_changep):
    (- SetEitherOrProperty({o}, {p}, false, {-adjective-definition:p}); -).
To change (o - object) to (w - value)
    (assignment operation):
    (- WriteValueProperty({o},{-convert-adjectival-constants:w},{w}); -).
To change (lv - existing variable) to (w - assignable-value)
    (assignment operation):
    (- {-assignment}; -).
```

§**25. Incrementing and decrementing.** It is not explicit in the following definitions that Inform should typecheck that the values held by these storage objects can be incremented or decremented (as a room, say, cannot, but a number or a height can): Inform nevertheless contains code which does this. Special cases in the type-checker are gradually moving into instructions in phrase preambles, but these haven't done so yet.

```
Section SR5/2/6 - Values and data structures - Increase and decrease

To increase/increment (p - property-value) by (w - value)
    (documented at ph_increase):
    (- Write{p}{-delete},{p}+{w}); -).
To increase/increment (gv - global variable) by (w - value):
    (- {gv} = {gv} + {w}; -).
To increase/increment (lv - existing variable) by (w - value):
    (- {lv} = {lv} + {w}; -).
To increase/increment (tr - table-reference) by (w - value):
    (- {tr}{-delete},2,{w}); -).
To decrease/decrement (p - property-value) by (w - value):
    (- Write{p}{-delete},{p}-{w}); -).
To decrease/decrement (gv - global variable) by (w - value):
    (- {gv} = {gv} - {w}; -).
To decrease/decrement (lv - existing variable) by (w - value):
    (- {lv} = {lv} - {w}; -).
To decrease/decrement (tr - table-reference) by (w - value):
    (- {tr}{-delete},3,{w}); -).
```

§**26. Tables.** And off we go into the world of tables, the code for which is all in "Tables.i6t". Note that changing a table entry is not here: it's above, with the phrases for changing other storage objects.

```
Section SR5/2/8 - Values and data structures - Tables

To decide which number is number of rows in/from (T - table-name)
    (documented at ph_numrows):
    (- TableRows({T}) -).
To decide which number is number of blank rows in/from (T - table-name)
    (documented at ph_numblank):
    (- TableBlankRows({T}) -).
To decide which number is number of filled rows in/from (T - table-name):
    (- TableFilledRows({T}) -).
To decide if there is (TR - table-reference)
    (documented at ph_thereis):
    (- (Exists{-do-not-dereference:TR}) -).
To decide if there is no (TR - table-reference):
    (- (Exists{-do-not-dereference:TR} == false) -).
To delete (tr - table-reference)
    (documented at ph_blankout):
    (- {tr}{-delete},4); -).
To blank out the whole row
    (documented at ph_blankout):
    (- {-require-ctvs}TableBlankOutRow(ct_0, ct_1); -).
To choose a/the/-- row (N - number) in/from (T - table-name)
    (documented at ph_chooserow):
    (- {-require-ctvs}ct_0 = {T}; ct_1 = {N}; -).
To choose a/the/-- row with (TC - table-column) of (w - value) in/from (T - table-name):
    (- {-require-ctvs}ct_0 = {T}; ct_1 = TableRowCorr(ct_0, {TC}, {w}); -).
To choose a/the/-- blank row in/from (T - table-name):
    (- {-require-ctvs}ct_0 = {T}; ct_1 = TableBlankRow(ct_0); -).
To choose a/the/-- random row in/from (T - table-name):
    (- {-require-ctvs}ct_0 = {T}; ct_1 = TableRandomRow(ct_0); -).
```

§**27.** Sorting.

```
Section SR5/2/9 - Values and data structures - Sorting tables

To sort (T - table-name) in random order
    (documented at ph_sort):
    (- TableShuffle({T}); -).
To sort (T - table-name) in (TC - table-column) order:
    (- TableSort({T}, {TC}, 1); -).
To sort (T - table-name) in reverse (TC - table-column) order:
    (- TableSort({T}, {TC}, -1); -).
```

§**28. Indexed text.** As repetitive as the following is, it's much simpler and less prone to possible namespace trouble if we don't define kinds of value for the different structural levels of text (character, word, punctuated word, etc.).

```
Section SR5/2/10 - Values and data structures - Indexed text

To decide what number is the number of characters in (txb - indexed text)
    (documented at ph_numofc):
    (- IT_BlobAccess({-pointer-to:txb}, CHR_BLOB) -).
To decide what indexed text is character number (N - a number) in (txb - indexed text):
    (- IT_GetBlob({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, {N}, CHR_BLOB) -).
To replace character number (N - a number) in (txb - indexed text)
    with (rtxb - indexed text):
    (- IT_ReplaceBlob(CHR_BLOB, {-pointer-to:txb}, {N}, {-pointer-to:rtxb}); -).

To decide what number is the number of words in (txb - indexed text):
    (- IT_BlobAccess({-pointer-to:txb}, WORD_BLOB) -).
To decide what indexed text is word number (N - a number) in (txb - indexed text):
    (- IT_GetBlob({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, {N}, WORD_BLOB) -).
To replace word number (N - a number) in (txb - indexed text)
    with (rtxb - indexed text):
    (- IT_ReplaceBlob(WORD_BLOB, {-pointer-to:txb}, {N}, {-pointer-to:rtxb}); -).

To decide what number is the number of punctuated words in (txb - indexed text):
    (- IT_BlobAccess({-pointer-to:txb}, PWORD_BLOB) -).
To decide what indexed text is punctuated word number (N - a number) in (txb - indexed text):
    (- IT_GetBlob({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, {N}, PWORD_BLOB) -).
To replace punctuated word number (N - a number) in (txb - indexed text)
    with (rtxb - indexed text):
    (- IT_ReplaceBlob(PWORD_BLOB, {-pointer-to:txb}, {N}, {-pointer-to:rtxb}); -).

To decide what number is the number of unpunctuated words in (txb - indexed text):
    (- IT_BlobAccess({-pointer-to:txb}, UWORD_BLOB) -).
To decide what indexed text is unpunctuated word number (N - a number) in (txb - indexed text):
    (- IT_GetBlob({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, {N}, UWORD_BLOB) -).
To replace unpunctuated word number (N - a number) in (txb - indexed text)
    with (rtxb - indexed text):
    (- IT_ReplaceBlob(UWORD_BLOB, {-pointer-to:txb}, {N}, {-pointer-to:rtxb}); -).

To decide what number is the number of lines in (txb - indexed text):
    (- IT_BlobAccess({-pointer-to:txb}, LINE_BLOB) -).
To decide what indexed text is line number (N - a number) in (txb - indexed text):
    (- IT_GetBlob({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, {N}, LINE_BLOB) -).
To replace line number (N - a number) in (txb - indexed text) with (rtxb - indexed text):
    (- IT_ReplaceBlob(LINE_BLOB, {-pointer-to:txb}, {N}, {-pointer-to:rtxb}); -).

To decide what number is the number of paragraphs in (txb - indexed text):
    (- IT_BlobAccess({-pointer-to:txb}, PARA_BLOB) -).
To decide what indexed text is paragraph number (N - a number) in (txb - indexed text):
    (- IT_GetBlob({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, {N}, PARA_BLOB) -).
To replace paragraph number (N - a number) in (txb - indexed text) with (rtxb - indexed text):
    (- IT_ReplaceBlob(PARA_BLOB, {-pointer-to:txb}, {N}, {-pointer-to:rtxb}); -).
```

§**29. Matching text.** A common matching engine is used for matching plain text...

```
Section SR5/2/11 - Values and data structures - Matching text
To decide if (txb - indexed text) exactly matches the text (ftxb - indexed text),
    case insensitively
    (documented at ph_exactm):
    (- IT_Replace_RE(CHR_BLOB,{-pointer-to:txb},{-pointer-to:ftxb},0,{phrase options},1) -).
To decide if (txb - indexed text) matches the text (ftxb - indexed text),
    case insensitively:
    (- IT_Replace_RE(CHR_BLOB,{-pointer-to:txb},{-pointer-to:ftxb},0,{phrase options}) -).
To decide what number is number of times (txb - indexed text) matches the text
    (ftxb - indexed text), case insensitively:
    (- IT_Replace_RE(CHR_BLOB,{-pointer-to:txb},{-pointer-to:ftxb},1,{phrase options}) -).
```

§**30.** ...and for regular expressions, though here we also have access to the exact text which matched (not interesting in the plain text case since it's the same as the search text, up to case at least), and the values of matched subexpressions (which the plain text case doesn't have).

```
To decide if (txb - indexed text) exactly matches the regular expression (ftxb - indexed text),
    case insensitively
    (documented at ph_regexp):
    (- IT_Replace_RE(REGEXP_BLOB,{-pointer-to:txb},{-pointer-to:ftxb},0,{phrase options},1) -).
To decide if (txb - indexed text) matches the regular expression (ftxb - indexed text),
    case insensitively:
    (- IT_Replace_RE(REGEXP_BLOB,{-pointer-to:txb},{-pointer-to:ftxb},0,{phrase options}) -).
To decide what number is number of times (txb - indexed text) matches the regular expression
    (ftxb - indexed text),case insensitively:
    (- IT_Replace_RE(REGEXP_BLOB,{-pointer-to:txb},{-pointer-to:ftxb},1,{phrase options}) -).
To decide what indexed text is text matching regular expression:
    (- IT_RE_GetMatchVar({-pointer-to-new:INDEXED_TEXT_TY}, 0) -).
To decide what indexed text is text matching subexpression (N - a number):
    (- IT_RE_GetMatchVar({-pointer-to-new:INDEXED_TEXT_TY}, {N}) -).
```

§**31. Replacing text.** The same engine, in "RegExp.i6t", handles replacement.

```
Section SR5/2/12 - Values and data structures - Replacing text
To replace the text (ftxb - indexed text) in (txb - indexed text) with (rtxb - indexed text),
    case insensitively
    (documented at ph_replace):
    (- IT_Replace_RE(REGEXP_BLOB, {-pointer-to:txb}, {-pointer-to:ftxb},
        {-pointer-to:rtxb}, {phrase options}); -).
To replace the regular expression (ftxb - indexed text) in (txb - indexed text) with
    (rtxb - indexed text), case insensitively:
    (- IT_Replace_RE(REGEXP_BLOB, {-pointer-to:txb}, {-pointer-to:ftxb},
        {-pointer-to:rtxb}, {phrase options}); -).
To replace the word (ftxb - indexed text) in (txb - indexed text) with
    (rtxb - indexed text):
    (- IT_ReplaceText(WORD_BLOB, {-pointer-to:txb}, {-pointer-to:ftxb}, {-pointer-to:rtxb}); -).
To replace the punctuated word (ftxb - indexed text) in (txb - indexed text)
    with (rtxb - indexed text):
    (- IT_ReplaceText(PWORD_BLOB, {-pointer-to:txb}, {-pointer-to:ftxb}, {-pointer-to:rtxb}); -).
```

§32. Casing of text.

```
Section SR5/2/13 - Values and data structures - Casing of text

To decide what indexed text is (txb - indexed text) in lower case
    (documented at ph_casing):
    (- IT_CharactersToCase({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, 0) -).
To decide what indexed text is (txb - indexed text) in upper case:
    (- IT_CharactersToCase({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, 1) -).
To decide what indexed text is (txb - indexed text) in title case:
    (- IT_CharactersToCase({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, 2) -).
To decide what indexed text is (txb - indexed text) in sentence case:
    (- IT_CharactersToCase({-pointer-to-new:INDEXED_TEXT_TY}, {-pointer-to:txb}, 3) -).
To decide if (txb - indexed text) is in lower case:
    (- IT_CharactersOfCase({-pointer-to:txb}, 0) -).
To decide if (txb - indexed text) is in upper case:
    (- IT_CharactersOfCase({-pointer-to:txb}, 1) -).
```

§**33. Lists.** The following are all for adding and removing values to dynamic lists:

```
Section SR5/2/14 - Values and data structures - Lists

To add (N - value = kov reference 1) to (L - list of values = list of kov marker 1),
    if absent
    (documented at ph_addlist):
    (- LIST_OF_TY_InsertItem({-pointer-to:L}, {N}, 0, 0, {phrase options}); -).
To add (N - value = kov reference 1) at entry (E - number) in
    (L - list of values = list of kov marker 1), if absent:
    (- LIST_OF_TY_InsertItem({-pointer-to:L}, {N}, 1, {E}, {phrase options}); -).
To add (LX - list of values = list of kov reference 1) to
    (L - list of values = list of kov marker 1), if absent:
    (- LIST_OF_TY_AppendList({-pointer-to:L}, {-pointer-to:LX}, 0, 0, {phrase options}); -).
To add (LX - list of values = list of kov reference 1) at entry (E - number)
    in (L - list of values = list of kov marker 1):
    (- LIST_OF_TY_AppendList({-pointer-to:L}, {-pointer-to:LX}, 1, {E}, 0); -).
To remove (N - value = kov reference 1) from (L - list of values = list of kov marker 1),
    if present
    (documented at ph_remlist):
    (- LIST_OF_TY_RemoveValue({-pointer-to:L}, {N}, {phrase options}); -).
To remove (N - list of values = list of kov reference 1) from
    (L - list of values = list of kov marker 1), if present:
    (- LIST_OF_TY_Remove_List({-pointer-to:L}, {-pointer-to:N}, {phrase options}); -).
To remove entry (N - number) from (L - list of values), if present:
    (- LIST_OF_TY_RemoveItemRange({-pointer-to:L}, {N}, {N}, {phrase options}); -).
To remove entries (N - number) to (N2 - number) from (L - list of values), if present:
    (- LIST_OF_TY_RemoveItemRange({-pointer-to:L}, {N}, {N2}, {phrase options}); -).
```

§**34.** Searching a list is implemented in a somewhat crude way at present, and the following syntax may later be replaced with a suitable verb "to be listed in", so that there's no need to imitate.

```
To decide if (N - value = kov reference 1) is listed in
    (L - list of values = list of kov marker 1)
    (documented at ph_islistedin):
    (- (LIST_OF_TY_FindItem({-pointer-to:L}, {N})) -).
To decide if (N - value = kov reference 1) is not listed in
    (L - list of values = list of kov marker 1):
    (- (LIST_OF_TY_FindItem({-pointer-to:L}, {N}) == false) -).
```

§**35.** The following are casts to and from other data types or objects. Lists are not the only I7 way to hold list-like data, because sometimes the memory requirements for dynamic lists are beyond what the virtual machine can sustain.

(a) A description is a representation of a set of objects by means of a predicate (e.g., "open unlocked doors"), and it converts into a list of current members (in creation order), but there's no reverse process.

(b) The multiple object list is a data structure used in the parser when processing commands like TAKE ALL.

```
To decide what list of objects is the list of (D - description)
    (documented at ph_listd):
    (- LIST_OF_TY_Desc({-pointer-to-new:LIST_OF_TY}, {D}) -).
To decide what list of values is the list of (D - domain-description)
    (amended kind of value 0):
    (- LIST_OF_TY_Desc({-pointer-to-new:LIST_OF_TY}, {D}, {-domain-kov:D}) -).
To decide what list of objects is the multiple object list
    (documented at ph_mobjl):
    (- LIST_OF_TY_Mol({-pointer-to-new:LIST_OF_TY}) -).
To alter the multiple object list to (L - list of objects):
    (- LIST_OF_TY_Set_Mol({-pointer-to:L}); -).
```

§**36.** Determining and setting the length:

```
Section SR5/2/15 - Values and data structures - Length of lists

To decide what number is the number of entries in/of (L - a list of values)
    (documented at ph_numel):
    (- LIST_OF_TY_GetLength({-pointer-to:L}) -).
To truncate (L - a list of values) to (N - a number) entries
    (documented at ph_truncate):
    (- LIST_OF_TY_SetLength({-pointer-to:L}, {N}, -1, 1); -).
To truncate (L - a list of values) to the first (N - a number) entries:
    (- LIST_OF_TY_SetLength({-pointer-to:L}, {N}, -1, 1); -).
To truncate (L - a list of values) to the last (N - a number) entries:
    (- LIST_OF_TY_SetLength({-pointer-to:L}, {N}, -1, -1); -).
To extend (L - a list of values) to (N - a number) entries:
    (- LIST_OF_TY_SetLength({-pointer-to:L}, {N}, 1); -).
To change (L - a list of values) to have (N - a number) entries:
    (- LIST_OF_TY_SetLength({-pointer-to:L}, {N}, 0); -).
```

§**37.** Easy but useful list operations:

```
Section SR5/2/16 - Values and data structures - Reversing and rotating lists

To reverse (L - a list of values)
    (documented at ph_revl):
    (- LIST_OF_TY_Reverse({-pointer-to:L}); -).
To rotate (L - a list of values)
    (documented at ph_rotl):
    (- LIST_OF_TY_Rotate({-pointer-to:L}, 0); -).
To rotate (L - a list of values) backwards:
    (- LIST_OF_TY_Rotate({-pointer-to:L}, 1); -).
```

§**38.** Sorting ultimately uses a common sorting mechanism, in "Sort.i6t", which handles both lists and tables.

```
Section SR5/2/17 - Values and data structures - Sorting lists

To sort (L - a list of values)
    (documented at ph_sortl):
    (- LIST_OF_TY_Sort({-pointer-to:L}, 1); -).
To sort (L - a list of values) in reverse order:
    (- LIST_OF_TY_Sort({-pointer-to:L}, -1); -).
To sort (L - a list of values) in random order:
    (- LIST_OF_TY_Sort({-pointer-to:L}, 2); -).
To sort (L - a list of objects) in (P - property) order:
    (- LIST_OF_TY_Sort({-pointer-to:L}, 1, {P}); -).
To sort (L - a list of objects) in reverse (P - property) order:
    (- LIST_OF_TY_Sort({-pointer-to:L}, -1, {P}); -).
```

§**39.** To call use options a "data structure" is a stretch. Still:

```
Section SR5/2/18 - Values and data structures - Use options

To decide whether using the/-- (UO - use-option)
    (documented at ph_testuo):
    (- (TestUseOption({UO})) -).
```

§**40.** Relations are the final data structure given here. In some ways they are the most fundamental of all, but they're not either set or tested by procedural phrases – they lie in the linguistic structure of conditions. So all we have here are the route-finding phrases:

```
Section SR5/2/19 - Values and data structures - Relations

To decide which object is next step via (R - abstract-relation)
    from (O1 - object) to (O2 - object)
    (documented at ph_nextstep):
    (- RelationRouteTo({R},{O1},{O2},false) -).
To decide which number is number of steps via (R - abstract-relation)
    from (O1 - object) to (O2 - object):
    (- RelationRouteTo({R},{O1},{O2},true) -).
```

§**41. Loops and conditionals.** While "unless" is supposed to be exactly like "if" but with the reversed sense of the condition, that isn't quite true. For example, there is no "unless ... then ...": logical it might be, English it is not.

```
Section SR5/3/1 - Loops and conditionals - If and unless

To if (c - condition) then (ph - phrase)
    (documented at ph_if):
    (- if {c} {ph} -).
To if (c - condition) , (ph - phrase):
    (- if {c} {ph} -).
To unless (c - condition) , (ph - phrase):
    (- if (~~{c}) {ph} -).
```

§**42.** It looks as if the definitions below could be abbreviated a little by making more use of the slash ("To else/otherwise if...", say), but in fact the slash isn't compatible with these built-in control structure definitions – or at any rate using it causes a handful of problem messages from the type-checker to be worded badly in some cases.

```
To otherwise if (c - condition):
    (- } else if {c} { -).
To else if (c - condition):
    (- } else if {c} { -).
To otherwise unless (c - condition):
    (- } else if (~~{c}) { -).
To else unless (c - condition):
    (- } else if (~~{c}) { -).
To otherwise (ph - phrase)
    (documented at ph_otherwise):
    (- else {ph} -).
To else (ph - phrase)
    (documented at ph_otherwise):
    (- else {ph} -).
To if (c - condition) begin -- end:
    (- if {c}  -).
To unless (c - condition) begin -- end:
    (- if (~~{c})  -).
```

§**43.** The switch form of "if" is subtly different, and here again "unless" is not allowed in its place.

The begin and end markers here are in a sense bogus, in that the end user isn't supposed to type them: they are inserted automatically in the sentence subtree maker, which converts indentation into block structure.

```
To if (V - word value) is begin -- end:
    (- switch({V})  -).
```

§**44.** After all that, the while loop is simplicity itself. Perhaps the presence of "unless" for "if" argues for a similarly negated form, "until" for "while", but users haven't yet petitioned for this.

```
Section SR5/3/2 - Loops and conditionals - While

To while (c - condition) repeatedly (ph - phrase)
    (documented at ph_while):
    (- while {c} {ph} -).
To while (c - condition) , (ph - phrase):
    (- while {c} {ph} -).
To while (c - condition) begin -- end:
    (- while {c}  -).
```

§**45.** The repeat loop looks like a single construction, but isn't, because the range can be given in four fundamentally different ways (and the loop variable then has a different kind of value accordingly). First, the equivalents of BASIC's `for` loop and of Inform 6's `objectloop`, respectively:

```
Section SR5/3/3 - Loops and conditionals - Repeat

To repeat with (loopvar - nonexisting number variable)
    running from (v - number) to (w - number) begin -- end
    (documented at ph_repeat):
        (- for ({loopvar}={v}: {loopvar}<={w}: {loopvar}++)  -).
To repeat with (loopvar - nonexisting object variable)
    running through (OS - description) begin -- end
    (documented at ph_runthrough):
        (- {-loop-over:OS}  -).
To repeat with (loopvar - nonexisting object variable)
    running through (OS - domain-description) begin -- end
    (documented at ph_runthrough):
        (- {-loop-over-domain:OS}  -).
```

§**46.** The following are all repeats where the range is the set of rows of a table, taken in some order, and the repeat variable – though it does exist – is never specified since the relevant row is instead the one selected during each iteration of the loop.

```
Section SR5/3/4 - Loops and conditionals - Repeat through tables

To repeat through (T - table-name) begin -- end
    (documented at ph_tabrepeat):
    (- {-push-ctvs}
        for ({-ct-v0}={T},{-ct-v1}=1,ct_0={-ct-v0},ct_1={-ct-v1}:
            {-ct-v1}<=TableRows({-ct-v0}):{-ct-v1}++,ct_0={-ct-v0},ct_1={-ct-v1})
            if (TableRowIsBlank(ct_0,ct_1)==false)  -).
To repeat through (T - table-name) in reverse order begin -- end:
    (- {-push-ctvs}
        for ({-ct-v0}={T},{-ct-v1}=TableRows({-ct-v0}),ct_0={-ct-v0},ct_1={-ct-v1}:
            {-ct-v1}>=1:{-ct-v1}--,ct_0={-ct-v0},ct_1={-ct-v1})
            if (TableRowIsBlank(ct_0,ct_1)==false)  -).
To repeat through (T - table-name) in (TC - table-column) order begin -- end:
    (- {-push-ctvs}
        for ({-ct-v0}={T},{-ct-v1}=TableNextRow({-ct-v0},{TC},0,1),ct_0={-ct-v0},ct_1={-ct-v1}:
            {-ct-v1}~=0:
            {-ct-v1}=TableNextRow({-ct-v0},{TC},{-ct-v1},1),ct_0={-ct-v0},ct_1={-ct-v1})  -).
```

```
To repeat through (T - table-name) in reverse (TC - table-column) order begin -- end:
    (- {-push-ctvs}
        for ({-ct-v0}={T},{-ct-v1}=TableNextRow({-ct-v0},{TC},0,-1),ct_0={-ct-v0},ct_1={-ct-v1}:
            {-ct-v1}~=0:
            {-ct-v1}=TableNextRow({-ct-v0},{TC},{-ct-v1},-1),ct_0={-ct-v0},ct_1={-ct-v1})  -).
```

§**47.** Finally, we can repeat through the other dynamic data structure: the list.

```
Section SR5/3/5 - Loops and conditionals - Repeat through lists

To repeat with (loopvar - nonexisting object variable)
    running through (L - list of values) begin -- end:
    (- {-loop-over-list:L}  -).
```

§**48.** The equivalent of `break` or `continue` in C or I6, or of `last` or `next` in Perl. Here "in loop" means "in any of the forms of while or repeat".

```
Section SR5/3/6 - Loops and conditionals - Changing the flow of loops

To break -- in loop (documented at ph_break):
    (- break; -).
To next -- in loop (documented at ph_next):
    (- continue; -).
```

§**49.** The following certainly aren't loops and aren't quite conditionals either, but they reflect the use of rules within rulebooks as being a form of control structure, and they have to be indexed somewhere.

The antique forms "yes" and "no" are now somewhat to be regretted, with "decide yes" and "decide no" being clearer ways to write the same thing. But we seem to be stuck with them.

```
Section SR5/3/7 - Loops and conditionals - Deciding outcomes

To yes
    (documented at ph_yes):
    (- rtrue; -) - in to decide if only.
To decide yes:
    (- rtrue; -) - in to decide if only.
To no:
    (- rfalse; -) - in to decide if only.
To decide no:
    (- rfalse; -) - in to decide if only.
```

§**50.** Note that returning a value has to invoke the type-checker to ensure that the return value matches the kind of value expected. This certainly rejects the phrase if it's used in a definition which isn't meant to be deciding a value at all, so an "in... only" clause is not needed.

```
To decide on (something - value)
    (documented at ph_result):
    (- return {-check-return-type:something}; -).
```

§**51.** "Do nothing" is useful mainly when other syntax has backed us into something clumsy, but it can't be dispensed with. (In the examples, it used to be used when conditions were awkward to negate – if condition, do nothing, otherwise blah blah blah – but the creation of "unless" made it possible to remove most of the "do nothing"s.)

```
Section SR5/3/8 - Loops and conditionals - Stop or go

To do nothing (documented at ph_nothing):
    (- ; -).
To stop (documented at ph_stop):
    (- return; -) - in to only.
```

§**52. Actions, activities and rules.** We begin with the firing off of new actions. The current action runs silently if the I6 global variable `keep_silent` is set, so the result of the definitions below is that one can go into silence mode, using "try silently", but not climb out of it again. This is done because many actions try other actions as part of their normal workings: if we want action X to be tried silently, then any action X itself tries should also be tried silently.

```
Section SR5/4/1 - Actions, activities and rules - Trying actions

To try (doing something - action)
    (documented at ph_try):
    (- {doing something}; -).
To silently try (doing something - action):
    (- @push keep_silent; keep_silent=1; {doing something}; @pull keep_silent; -).
To try silently (doing something - action):
    (- @push keep_silent; keep_silent=1; {doing something}; @pull keep_silent; -).
```

§**53.** The requirements of the current action can be tested. The following may be reimplemented using a verb *to require* at some future point.

```
Section SR5/4/2 - Actions, activities and rules - Action requirements

To decide whether the action requires a touchable noun
    (documented at ph_requires):
    (- (NeedToTouchNoun()) -).
To decide whether the action requires a touchable second noun:
    (- (NeedToTouchSecondNoun()) -).
To decide whether the action requires a carried noun:
    (- (NeedToCarryNoun()) -).
To decide whether the action requires a carried second noun:
    (- (NeedToCarrySecondNoun()) -).
To decide whether the action requires light:
    (- (NeedLightForAction()) -).
```

§**54.** Within the rulebooks to do with an action, returning `true` from a rule is sufficient to stop the rulebook early: there is no need to specify success or failure because that is determined by the rulebook itself. (For instance, if the check taking rules stop for any reason, the action failed; if the after rules stop, it succeeded.) In some rulebooks, notably "instead" and "after", the default is to stop, so that execution reaching the end of the I6 routine for a rule will run into an `rtrue`. "Continue the action" prevents this.

```
Section SR5/4/3 - Actions, activities and rules - Stop or continue

To stop the action
    (documented at ph_stopac):
    (- rtrue; -) - in to only.
To continue the action:
    (- rfalse; -) - in to only.
```

§**55.** Note that we define "try", "silently try" and "try silently" all over again here, but for stored actions rather than actions: NI's type-checking means that it will automatically use whichever definition is appropriate.

```
Section SR5/4/4 - Actions, activities and rules - Stored actions

To decide what stored action is the current action
    (documented at ph_curract):
    (- STORED_ACTION_TY_Current({-pointer-to-new:STORED_ACTION_TY}) -).
To decide what stored action is the action of (A - action):
    (- {A}{-delete}{-delete}, STORED_ACTION_TY_Current({-pointer-to-new:STORED_ACTION_TY})) -).
To try (S - stored action):
    (- STORED_ACTION_TY_Try({S}); -).
To silently try (S - stored action):
    (- STORED_ACTION_TY_Try({S}, true); -).
To try silently (S - stored action):
    (- STORED_ACTION_TY_Try({S}, true); -).
To decide if (act - a stored action) involves (X - an object)
    (documented at ph_involves):
    (- (STORED_ACTION_TY_Involves({-pointer-to:act}, {X})) -).
To decide what action-name is the action-name part of (act - a stored action):
    (- (STORED_ACTION_TY_Part({-pointer-to:act}, 0)) -).
To decide what object is the noun part of (act - a stored action):
    (- (STORED_ACTION_TY_Part({-pointer-to:act}, 1)) -).
To decide what object is the second noun part of (act - a stored action):
    (- (STORED_ACTION_TY_Part({-pointer-to:act}, 2)) -).
To decide what object is the actor part of (act - a stored action):
    (- (STORED_ACTION_TY_Part({-pointer-to:act}, 3)) -).
```

§**56.** Firing off activities:

```
Section SR5/4/5 - Actions, activities and rules - Carrying out activities

To carry out the (A - activity) activity
    (documented at ph_carryout):
    (- CarryOutActivity({A}); -).
To carry out the (A - activity) activity with (O - object):
    (- CarryOutActivity({A}, {O}); -).
```

§**57.** The following circumlocutions are needed because, at present, we can't define adjectives for kinds of value other than "object".

```
[To decide whether (A - activity) activity is going on
    (documented at ph_goingon):
    (- (TestActivity({A})) -).
To decide whether (A - activity) activity is not going on:
    (- (~~(TestActivity({A}))) -).
To decide whether (A - activity) activity is empty:
    (- (ActivityEmpty({A})) -).
To decide whether (A - activity) activity is not empty:
    (- (~~(ActivityEmpty({A}))) -).]
```

§**58.** This is analogous to "continue the action":

```
To continue the activity:
    (- rfalse; -) - in to only.
```

§**59.** Advanced activity phrases: for setting up one's own activities structured around I7 source text. People tend not to use this much, and perhaps that's a good thing, but it does open up possibilities, and it's good for retro-fitting onto extensions to make the more customisable.

```
Section SR5/4/6 - Actions, activities and rules - Advanced activities

To begin the (A - activity) activity
    (documented at ph_beginact):
    (- BeginActivity({A}); -).
To begin the (A - activity) activity with (O - object):
    (- BeginActivity({A}, {O}); -).
To decide whether handling (A - activity) activity:
    (- (~~(ForActivity({A}))) -).
To decide whether handling (A - activity) activity with (O - object):
    (- (~~(ForActivity({A}, {O}))) -).
To end the (A - activity) activity:
    (- EndActivity({A}); -).
To end the (A - activity) activity with (O - object):
    (- EndActivity({A}, {O}); -).
To abandon the (A - activity) activity:
    (- AbandonActivity({A}); -).
To abandon the (A - activity) activity with (O - object):
    (- AbandonActivity({A}, {O}); -).
```

§**60. Rules.** Four different ways to invoke a rule or rulebook:

```
Section SR5/4/7 - Actions, activities and rules - Following rules

To follow (RL - a rule)
    (documented at ph_follow):
    (- FollowRulebook({RL}); -).
To follow (RL - a rule) for (O - object):
    (- FollowRulebook({RL}, {O}, true); -).
To consider (RL - a rule)
    (documented at ph_consider):
    (- ProcessRulebook({RL}); -).
To consider (RL - a rule) for (O - object):
    (- ProcessRulebook({RL}, {O}, true); -).
To abide by (RL - a rule)
    (documented at ph_abide):
    (- if (ProcessRulebook({RL})) rtrue; -) - in to only.
To abide by (RL - a rule) for (O - object):
    (- if (ProcessRulebook({RL}, {O}, true)) rtrue; -) - in to only.
To anonymously abide by (RL - a rule):
    (- if (temporary_value = ProcessRulebook({RL})) {
        if (RulebookSucceeded()) ActRulebookSucceeds(temporary_value);
        else ActRulebookFails(temporary_value);
        rtrue;
    } -) - in to only.
To anonymously abide by (RL - a rule) for (O - object):
    (- if (temporary_value = ProcessRulebook({RL}, {O}, true)) {
        if (RulebookSucceeded()) ActRulebookSucceeds(temporary_value);
        else ActRulebookFails(temporary_value);
        rtrue;
    } -) - in to only.
```

§**61.** Rules return `true` to indicate a decision, which could be either a success or a failure, and optionally may also return a value. If they return `false`, there's no decision.

```
Section SR5/4/8 - Actions, activities and rules - Success and failure

To make no decision: (- rfalse; -) - in to only.
To rule succeeds
    (documented at ph_succeeds):
    (- RulebookSucceeds(); rtrue; -) - in to only.
To rule fails:
    (- RulebookFails(); rtrue; -) - in to only.
To rule succeeds with result (O - a miscellaneous-value):
    (- RulebookSucceeds(true,{O}); rtrue; -) - in to only.
To rule fails with result (O - a miscellaneous-value):
    (- RulebookFails(true,{O}); rtrue; -) - in to only.
To decide if rule succeeded:
    (- (RulebookSucceeded()) -).
To decide if rule succeeded with result (O - miscellaneous-value):
    (- ((RulebookSucceeded()) && (ResultOfRule() == {O})) -).
To decide if rule failed:
    (- (RulebookFailed()) -).
To decide if rule failed with result (O - miscellaneous-value):
```

```
    (- ((RulebookFailed()) && (ResultOfRule() == {0})) -).
To decide which miscellaneous-value is the result of the rule
    (documented at ph_resultr):
    (- (ResultOfRule()) -).
To decide which rulebook-outcome is the outcome of the rulebook
    (documented at ph_outcomer):
    (- (ResultOfRule()) -).
```

§**62.** And lastly the suite of procedural rule tricks, though happily these have been less and less needed as Inform has grown in flexibility. (They incur an appreciable speed penalty at run-time.)

```
Section SR5/4/9 - Actions, activities and rules - Procedural manipulation

To ignore (RL - a rule)
    (documented at ph_ignore):
    (- SuppressRule({RL}); -).
To reinstate (RL - a rule):
    (- ReinstateRule({RL}); -).
To reject the result of (RL - a rule):
    (- DonotuseRule({RL}); -).
To accept the result of (RL - a rule):
    (- DonotuseRule({RL}); -).
To substitute (RL1 - a rule) for (RL2 - a rule):
    (- SubstituteRule({RL1},{RL2}); -).
To restore the original (RL1 - a rule):
    (- SubstituteRule({RL1},{RL1}); -).
To move (RL1 - a rule) to before (RL2 - a rule):
    (- MoveRuleBefore({RL1},{RL2}); -).
To move (RL1 - a rule) to after (RL2 - a rule):
    (- MoveRuleAfter({RL1},{RL2}); -).
```

§**63. The model world.** The score and outcome of play phrases only interface with two I6 library variables, `score` and `deadflag`. The latter takes values 0 (in progress), 1 (lost), 2 (won), or the packed address of a string or routine to print a string which explains in what way the world ended ("You have sailed off into the sunset").

```
Section SR5/5/1 - Model world - Score

To award (some - number) point/points
    (documented at ph_awardp):
    (- score=score+{some}; -).
```

§**64.** Phrase definitions with wordings like "the game is in progress" are a necessary evil. The "is" here is parsed literally, not as the present tense of *to be*, so inflected forms like "the game had been in progress" are not available: nor is there any value "the game" for the subject noun phrase to hold, nor can the relation "in"... and so on. Ideally, we would word all conditional phrases so as to avoid the verbs, but natural language just doesn't work that way.

```
Section SR5/5/2 - Model world - Outcome of play

To end the game in death (documented at ph_end): (- deadflag=1; -).
To end the game in victory: (- deadflag=2; -).
To end the game saying (finale - text): (- deadflag={finale}; -).
To resume the game: (- resurrect_please = true; -).
To decide whether the game is in progress: (- (deadflag==0) -).
To decide whether the game is over: (- (deadflag~=0) -).
To decide whether the game ended in death: (- (deadflag==1) -).
To decide whether the game ended in victory: (- (deadflag==2) -).
```

§**65.** Times of day.

```
Section SR5/5/3 - Model world - Times of day

To decide which number is the minutes part of (t - time)
    (documented at ph_minspart):
    (- ({t}%ONE_HOUR) -).
To decide which number is the hours part of (t - time):
    (- ({t}/ONE_HOUR) -).
```

§**66.** Comparing times of day is inherently odd, because the day is circular. Every 2 PM comes after a 1 PM, but it also comes before another 1 PM. Where do we draw the meridian on this circle? The legal day divides at midnight but for other purposes (daylight savings time, for instance) society often chooses 2 AM as the boundary. Inform uses 4 AM instead as the least probable time through which play continues. (Modulo a 24-hour clock, adding 20 hours is equivalent to subtracting 4 AM from the current time: hence the use of `20*ONE_HOUR` below.) Thus 3:59 AM is after 4:00 AM, the former being at the very end of a day, the latter at the very beginning.

```
To decide if (t - time) is before (t2 - time)
    (documented at ph_timeshift):
    (- ((({t}+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))<(({t2}+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))) -).
To decide if (t - time) is after (t2 - time):
    (- ((({t}+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))>(({t2}+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))) -).
To decide if it is before (t2 - time):
    (- (((the_time+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))<(({t2}+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))) -).
To decide if it is after (t2 - time):
    (- (((the_time+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))>(({t2}+20*ONE_HOUR)%(TWENTY_FOUR_HOURS))) -).
To decide which time is (t - time) before (t2 - time)
    (documented at ph_timeshift):
    (- (({t2}-{t}+TWENTY_FOUR_HOURS)%(TWENTY_FOUR_HOURS)) -).
To decide which time is (t - time) after (t2 - time):
    (- (({t2}+{t}+TWENTY_FOUR_HOURS)%(TWENTY_FOUR_HOURS)) -).
```

§**67.** Durations are in effect casts from “number” to “time”.

```
Section SR5/5/4 - Model world - Durations

To decide which time is (n - number) minutes
    (documented at ph_durations):
    (- (({n})%(TWENTY_FOUR_HOURS)) -).
To decide which time is (n - number) hours:
    (- (({n}*ONE_HOUR)%(TWENTY_FOUR_HOURS)) -).
```

§**68.** Timed events.

```
Section SR5/5/5 - Model world - Timed events

To (R - rule) in (t - number) turn from now
    (documented at ph_future):
    (- SetTimedEvent({R}, {t}+1, 0); -).
To (R - rule) in (t - number) turns from now:
    (- SetTimedEvent({R}, {t}+1, 0); -).
To (R - rule) at (t - time):
    (- SetTimedEvent({R}, {t}, 1); -).
To (R - rule) in (t - time) from now:
    (- SetTimedEvent({R}, (the_time+{t})%(TWENTY_FOUR_HOURS), 1); -).
```

§**69.** Scenes.

```
Section SR5/5/6 - Model world - Scenes

To decide if (sc - scene) has happened:
    (- (scene_endings-->({sc}-1)) -).
To decide if (sc - scene) has not happened:
    (- (scene_endings-->({sc}-1) == 0) -).
To decide if (sc - scene) has ended:
    (- (scene_endings-->({sc}-1) > 1) -).
To decide if (sc - scene) has not ended:
    (- (scene_endings-->({sc}-1) <= 1) -).
```

§**70.** Timing of scenes.

```
Section SR5/5/7 - Model world - Timing of scenes

To decide which time is the time since (sc - scene) began
    (documented at ph_tsince):
    (- (SceneUtility({sc}, 1)) -).
To decide which time is the time when (sc - scene) began:
    (- (SceneUtility({sc}, 2)) -).
To decide which time is the time since (sc - scene) ended:
    (- (SceneUtility({sc}, 3)) -).
To decide which time is the time when (sc - scene) ended:
    (- (SceneUtility({sc}, 4)) -).
```

§**71.** Player's identity and location.

```
Section SR5/5/8 - Model world - Player's identity and location

To change the/-- player to (O - an object)
    (documented at ph_changep):
    (- ChangePlayer({O}); -).
To decide whether in (somewhere - an object):
    (- (WhetherIn({somewhere})) -).
To decide whether in darkness
    (documented at ph_indarkness):
    (- (location==thedark) -).
```

§**72.** Moving and removing things.

```
Section SR5/5/9 - Model world - Moving and removing things

To move (something - object) to (something else - object),
    without printing a room description
    or printing an abbreviated room description
    (documented at ph_move):
    (- MoveObject({something}, {something else}, {phrase options}, false); -).
To remove (something - object) from play
    (documented at ph_remove):
    (- RemoveFromPlay({something}); -).
To move (O - object) backdrop to all (D - description)
    (documented at ph_movebd):
    (- MoveBackdrop({O}, {D}); -).
To update backdrop positions
    (documented at ph_updatebp):
    (- MoveFloatingObjects(); -).
```

§**73.** The map.

```
Section SR5/5/10 - Model world - The map

To decide which room is location of (O - object)
    (documented at ph_locof):
    (- LocationOf({O}) -).
To decide which room is room (D - direction) from/of (R1 - room)
    (documented at ph_roomdirof):
    (- MapConnection({R1},{D}) -).
To decide which door is door (D - direction) from/of (R1 - room)
    (documented at ph_roomdirof):
    (- DoorFrom({R1},{D}) -).
To decide which object is the other side of (D - door) from (R1 - room):
    (- OtherSideOfDoor({D},{R1}) -).
To decide which object is the direction of (D - door) from (R1 - room):
    (- DirectionDoorLeadsIn({D},{R1}) -).
To decide which object is room-or-door (D - direction) from/of (R1 - room):
    (- RoomOrDoorFrom({R1},{D}) -).
To change (D - direction) exit of (R1 - room) to (R2 - room)
    (documented at ph_changex):
    (- AssertMapConnection({R1},{D},{R2}); -).
To change (D - direction) exit of (R1 - room) to nothing/nowhere:
    (- AssertMapConnection({R1},{D},nothing); -).
To decide which room is the front side of (D - object)
    (documented at ph_frontside):
    (- FrontSideOfDoor({D}) -).
To decide which room is the back side of (D - object):
    (- BackSideOfDoor({D}) -).
```

§**74.** Route-finding.

```
Section SR5/5/11 - Model world - Route-finding

To decide which object is best route from (R1 - object) to (R2 - object),
    using doors or using even locked doors
    (documented at ph_bestroute):
    (- MapRouteTo({R1},{R2},0,{phrase options}) -).
To decide which number is number of moves from (R1 - object) to (R2 - object),
    using doors or using even locked doors:
    (- MapRouteTo({R1},{R2},0,{phrase options},true) -).
To decide which object is best route from (R1 - object) to (R2 - object) through
    (RS - description),
    using doors or using even locked doors:
    (- MapRouteTo({R1},{R2},{RS},{phrase options}) -).
To decide which number is number of moves from (R1 - object) to (R2 - object) through
    (RS - description),
    using doors or using even locked doors:
    (- MapRouteTo({R1},{R2},{RS},{phrase options},true) -).
```

§**75.** The object tree.

```
Section SR5/5/12 - Model world - The object tree

To decide which object is holder of (something - object)
    (documented at ph_holder):
    (- (HolderOf({something})) -).
To decide which object is next thing held after (something - object):
    (- (sibling({something})) -).
To decide which object is first thing held by (something - object):
    (- (child({something})) -).
```

§**76. Understanding.** First, asking yes/no questions.

```
Section SR5/6/1 - Understanding - Asking yes/no questions

To decide whether player consents
    (documented at ph_consents):
        (- YesOrNo() -).
```

§**77.** Support for snippets, which are substrings of the player's command.

```
Section SR5/6/2 - Understanding - The player's command

To decide if (S - a snippet) matches (T - a topic)
    (documented at act_reading):
    (- (SnippetMatches({S}, {T})) -).
To decide if (S - a snippet) does not match (T - a topic)
    (documented at act_reading):
    (- (SnippetMatches({S}, {T}) == false) -).
To decide if (S - a snippet) includes (T - a topic):
    (- (matched_text=SnippetIncludes({T},{S})) -).
To decide if (S - a snippet) does not include (T - a topic):
    (- (SnippetIncludes({T},{S})==0) -).
```

§**78.** Changing the player's command.

```
Section SR5/6/3 - Understanding - Changing the player's command

To change the text of the player's command to (txb - indexed text)
    (documented at act_reading):
    (- SetPlayersCommand({-pointer-to:txb}); -).
To replace (S - a snippet) with (T - text):
    (- SpliceSnippet({S}, {T}); -).
To cut (S - a snippet):
    (- SpliceSnippet({S}, 0); -).
To reject the player's command:
    (- RulebookFails(); rtrue; -) - in to only.
```

§**79.** Scope and pronouns.

```
Section SR5/6/4 - Understanding - Scope and pronouns

To place (O - an object) in scope, but not its contents
    (documented at ph_scope):
    (- PlaceInScope({O}, {phrase options}); -).
To place the/-- contents of (O - an object) in scope
    (documented at ph_scope):
    (- ScopeWithin({O}); -).
To set pronouns from possessions of the player:
    (- PronounNoticeHeldObjects(); -).
To set pronouns from (O - an object):
    (- PronounNotice({O}); -).
```

§**80.** The I6 parser errors cry out to be an enumerated kind of value, and probably will be in a later build. The following will then be more concise.

```
Section SR5/6/5 - Understanding - I6 parser errors

To decide whether parser error is didn't understand
    (documented at act_parsererror):
    (- (etype == STUCK_PE) -).
To decide whether parser error is only understood as far as:
    (- (etype == UPTO_PE) -).
To decide whether parser error is didn't understand that number:
    (- (etype == NUMBER_PE) -).
To decide whether parser error is can't see any such thing:
    (- (etype == CANTSEE_PE) -).
To decide whether parser error is said too little:
    (- (etype == TOOLIT_PE) -).
To decide whether parser error is aren't holding that:
    (- (etype == NOTHELD_PE) -).
To decide whether parser error is can't use multiple objects:
    (- (etype == MULTI_PE) -).
To decide whether parser error is can only use multiple objects:
    (- (etype == MMULTI_PE) -).
To decide whether parser error is not sure what it refers to:
    (- (etype == VAGUE_PE) -).
To decide whether parser error is excepted something not included:
    (- (etype == EXCEPT_PE) -).
To decide whether parser error is can only do that to something animate:
    (- (etype == ANIMA_PE) -).
To decide whether parser error is not a verb I recognise:
    (- (etype == VERB_PE) -).
To decide whether parser error is not something you need to refer to:
    (- (etype == SCENERY_PE) -).
To decide whether parser error is can't see it at the moment:
    (- (etype == ITGONE_PE) -).
To decide whether parser error is didn't understand the way that finished:
    (- (etype == JUNKAFTER_PE) -).
To decide whether parser error is not enough of those available:
    (- (etype == TOOFEW_PE) -).
To decide whether parser error is nothing to do:
    (- (etype == NOTHING_PE) -).
To decide whether parser error is I beg your pardon:
    (- (etype == BLANKLINE_PE) -).
To decide whether parser error is noun did not make sense in that context:
    (- (etype == NOTINCONTEXT_PE) -).
```

§**81. Using external resources.** The following all refer to "FileIO.i6t" and work only on Glulx.

```
Section SR5/7/1 - Using external resources - Files

To read (filename - external-file) into (T - table-name)
    (documented at ph_filetables):
    (- FileIO_GetTable({filename}, {T}); -).
To write (filename - external-file) from (T - table-name):
    (- FileIO_PutTable({filename}, {T}); -).
To decide if (filename - external-file) exists:
    (- (FileIO_Exists({filename}, false)) -).
To decide if ready to read (filename - external-file)
    (documented at ph_readytr):
    (- (FileIO_Ready({filename}, false)) -).
To mark (filename - external-file) as ready to read:
    (- FileIO_MarkReady({filename}, true); -).
To mark (filename - external-file) as not ready to read:
    (- FileIO_MarkReady({filename}, false); -).
To write (T - text) to (FN - external-file)
    (documented at ph_writef):
    (- FileIO_PutContents({FN}, {-allow-stack-frame-access:T}, false); -).
To append (T - text) to (FN - external-file):
    (- FileIO_PutContents({FN}, {-allow-stack-frame-access:T}, true); -).
To say text of (FN - external-file):
    (- FileIO_PrintContents({FN}); say__p = 1; -).
```

§**82.** Figures and sound effects. Ditto, but for "Figures.i6t".

```
Section SR5/7/2 - Using external resources - Figures and sound effects

To display (F - figure-name), one time only
    (documented at ph_displayf):
    (- DisplayFigure({F}, {phrase options}); -).
To play (SFX - sound-name), one time only
    (documented at ph_playsf):
    (- PlaySound({SFX}, {phrase options}); -).
```

§**83. Message support.** "Unindexed" here is a euphemism for "undocumented". This is where experimental or intermediate phrases go: things we don't want people to use because we will probably revise them heavily in later builds of Inform. For now, the Standard Rules do make use of these phrases, but nobody else should. They will change without comment in the change log.

```
Section SR5/8/1 - Message support - Issuance - Unindexed

To stop the action with library message (AN - an action-name) number
    (N - a number) for (H - an object):
    (- return GL__M({AN},{N},{H}); -) - in to only.
To stop the action with library message (AN - an action-name) number
    (N - a number):
    (- return GL__M({AN},{N},noun); -) - in to only.
To issue miscellaneous library message number (N - a number):
    (- GL__M(##Miscellany,{N}); -).
To issue library message (AN - an action-name) number
    (N - a number) for (H - an object):
    (- GL__M({AN},{N},{H}); -).
To issue library message (AN - an action-name) number (N - a number):
    (- GL__M({AN},{N},noun); -).
To issue actor-based library message (AN - an action-name) number
    (N - a number) for (H - an object) and (H2 - an object):
    (- AGL__M({AN},{N},{H},{H2}); -).
To issue actor-based library message (AN - an action-name) number
    (N - a number) for (H - an object):
    (- AGL__M({AN},{N},{H}); -).
To issue actor-based library message (AN - an action-name) number (N - a number):
    (- AGL__M({AN},{N},noun); -).

To issue score notification message:
    (- NotifyTheScore(); -).
To say pronoun dictionary word:
    (- print (address) pronoun_word; -).
To say recap of command:
    (- PrintCommand(); -).
The pronoun reference object is an object that varies.
The pronoun reference object variable translates into I6 as "pronoun_obj".
The library message action is an action-name that varies.
The library message action variable translates into I6 as "lm_act".
The library message number is a number that varies.
The library message number variable translates into I6 as "lm_n".
The library message amount is a number that varies.
The library message amount variable translates into I6 as "lm_o".
The library message object is an object that varies.
The library message object variable translates into I6 as "lm_o".
The library message actor is an object that varies.
The library message actor variable translates into I6 as "actor".
The second library message object is an object that varies.
The second library message object variable translates into I6 as "lm_o2".
```

§**84.** Intervention. These are hooks for the new library messages system coming in a later build; they won't last.

```
Section SR5/8/2 - Message support - Intervention - Unindexed

To decide if intervened in miscellaneous message:
    decide on false;

To decide if intervened in miscellaneous list message:
    decide on false;

To decide if intervened in action message:
    decide on false;
```

§**85. Miscellaneous other phrases.** Again, *these are not part of Inform's public specification.*

```
Section SR5/9/1 - Miscellaneous other phrases - Unindexed
```

§**86.** These are actually sensible concepts in the world model, and could even be opened to public use, but they're quite complicated to explain.

```
To decide which object is the component parts core of (X - an object):
    (- CoreOf({X}) -).
To decide which object is the common ancestor of (O - an object) with
    (P - an object):
    (- (CommonAncestor({O}, {P})) -).
To decide which object is the not-counting-parts holder of (O - an object):
    (- (CoreOfParentOfCoreOf({O})) -).
To decide which object is the visibility-holder of (O - object):
    (- VisibilityParent({O}) -).
To calculate visibility ceiling at low level:
    (- FindVisibilityLevels(); -).
```

§**87.** These are in effect global variables, but aren't defined as such, to prevent people using them. Their contents are only very briefly meaningful, and they would be dangerous friends to know.

```
To decide which number is the visibility ceiling count calculated:
    (- visibility_levels -).
To decide which object is the visibility ceiling calculated:
    (- visibility_ceiling -).
```

§**88.** This is a unique quasi-action, using the secondary action processing stage only. A convenience, but also an anomaly, and let's not encourage its further use.

```
To produce a room description with going spacing conventions:
    (- LookAfterGoing(); -).
```

§**89.** Two ugly little tricks needed because of the mismatch between I6 and I7 property implementation, and because of legacy code from the old I6 library. Please don't touch.

```
To print the location's description:
    (- PrintOrRun(location, description); -).
To decide if (O - object) goes undescribed by source text:
    (- ({O}.description == 0) -).
```

§**90.** This is a bit trickier than it looks, because it isn't always set when one thinks it is.

```
To decide whether the I6 parser is running multiple actions:
    (- (multiflag==1) -).
```

§**91.** Again, the following cries out for an enumerated kind of value.

```
To decide if set to sometimes abbreviated room descriptions:
    (- (lookmode == 1) -).
To decide if set to unabbreviated room descriptions:
    (- (lookmode == 2) -).
To decide if set to abbreviated room descriptions:
    (- (lookmode == 3) -).
```

§**92.** Action conversion is a trick used in the Standard Rules to simplify the implementation of actions: it allows one action to become another one mid-way, without causing spurious action failures. (There are better ways to make user-defined actions convert, and some of the examples show this.)

```
To convert to (AN - an action-name) on (O - an object):
    (- return GVS_Convert({AN},{O},0); -) - in to only.
To convert to request of (X - object) to perform (AN - action-name) with
    (Y - object) and (Z - object):
    (- TryAction(true, {X}, {AN}, {Y}, {Z}); rtrue; -).
To convert to special going-with-push action:
    (- ConvertToGoingWithPush(); rtrue; -).
```

§**93.** The "surreptitiously" phrases shouldn't be used except in the Standard Rules because they temporarily violate invariants for the object tree and the light variables; the SR uses them carefully in situations where it's known to work out all right.

```
To surreptitiously move (something - object) to (something else - object):
    (- move {something} to {something else}; -).
To surreptitiously move (something - object) to (something else - object) during going:
    (- MoveDuringGoing({something}, {something else}); -).
To surreptitiously reckon darkness:
    (- SilentlyConsiderLight(); -).
```

§**94.** And so, at last...

```
The Standard Rules end here.
```

§**95.** ...except that this is not quite true, because like most extensions they then quote some documentation for Inform to weave into index pages: though here it's more of a polite refusal than a manual, since the entire system documentation is really the description of what was defined in this extension.

```
---- DOCUMENTATION ----
Unlike other extensions, the Standard Rules are compulsorily included
with every project. They define the phrases, kinds and relations which
are basic to Inform, and which are described throughout the documentation.
```

B The Template Layer

`B/introt`: *Introduction.i6t* A short introduction to the template and its organisation.

`B/maint`: *Main.i6t* The top-level logic of NI: the sequence of operations followed by NI up to the point where the output file is opened, resuming after it is closed again.

`B/typet`: *Types.i6t* To set up the atomic kinds of value (the base data types, in other words) within NI.

`B/outt`: *Output.i6t* This is the superstructure of the file of I6 code output by NI: from ICL commands at the top down to the signing-off comments at the bottom.

`B/defnt`: *Definitions.i6t* Miscellaneous constant definitions, usually providing symbolic names for otherwise inscrutable numbers, which are used throughout the template layer.

`B/ordt`: *OrderOfPlay.i6t* The sequence of events in play: the Main routine which runs the startup rulebook, the turn sequence rulebook and the shutdown rulebook; and most of the I6 definitions of primitive rules in those rulebooks.

`B/actt`: *Actions.i6t* To try actions by people in the model world, processing the necessary rulebooks.

`B/acvt`: *Activities.i6t* To run the necessary rulebooks to carry out an activity.

`B/rbt`: *Rulebooks.i6t* To work through the rules in a rulebook until a decision is made.

`B/parst`: *Parser.i6t* The parser for turning the text of the typed command into a proposed action by the player.

`B/lwt`: *ListWriter.i6t* A flexible object-lister taking care of plurals, inventory information, various formats and so on.

`B/oowt`: *OutOfWorld.i6t* To implement some of the out of world actions.

`B/wmt`: *WorldModel.i6t* Testing and changing the fundamental spatial relations.

`B/light`: *Light.i6t* The determination of light, visibility and physical access.

`B/testt`: *Tests.i6t* The command grammar and I6 implementation for testing commands such as TEST, ACTIONS and PURLOIN.

`B/langt`: *Language.i6t* The fundamental definitions needed by the parser and the verb library in order to specify the language of play – that is, the language used for communications between the story file and the player.

`B/stackt`: *MStack.i6t* To allocate space on the memory stack for frames of variables to be used by rulebooks, activities and actions.

`B/chrt`: *Chronology.i6t* To record information now which will be needed later, when a condition phrased in the perfect tense is tested.

`B/print`: *Printing.i6t* To manage the line skips which space paragraphs out, and to handle the printing of names of objects, pieces of text and numbers.

`B/rtpt`: *RTP.i6t* To issue run-time problem messages, and to perform some run-time type checking which may issue such messages.

`B/utilt`: *Utilities.i6t* Miscellaneous utility routines for some fundamental I6 needs.

`B/numt`: *Number.i6t* Support for parsing integers.

`B/timet`: *Time.i6t* Support for parsing and printing times of day.

`B/tabt`: *Tables.i6t* To read, write, search and allocate rows in the Table data structure.

`B/sortt`: *Sort.i6t* To sort arrays.

`B/relt`: *Relations.i6t* To manage run-time storage for relations between objects, and to find routes through relations and the map.

`B/figst`: *Figures.i6t* To display figures and play sound effects.

`B/inxt`: *IndexedText.i6t* Code to support the indexed text kind of value.

`B/regxt`: *RegExp.i6t* Code to match and replace on regular expressions against indexed text strings.

`B/chart`: *Char.i6t* To decide whether letters are upper or lower case, and convert between the two.

`B/unict`: *UnicodeData.i6t* To tabulate casings in the character set.

`B/stact`: *StoredAction.i6t* Code to support the stored action kind of value.

`B/listt`: *Lists.i6t* Code to support the list of... kind of value constructor.

`B/blkvt`: *BlockValues.i6t* Routines for copying, comparing, creating and destroying block values, and for reading and writing them as if they were arrays.

`B/flext`: *Flex.i6t* To allocate flexible-sized blocks of memory as needed to hold arbitrary-length strings of text, stored actions or other block values.

`B/zmt`: *ZMachine.i6t* To provide routines handling low-level Z-machine facilities.

`B/glut`: *Glulx.i6t* To start up the Glk interface for the Glulx virtual machine, and provide Glulx-specific printing functions.

`B/iot`: *FileIO.i6t* Reading and writing external files, in the Glulx virtual machine only.

Introduction Template B/introt

Purpose

A short introduction to the template and its organisation.

§**1. The Software Stack.** The term "software stack" is sometimes used to refer to the total body of code running in a computer. As the word "stack" implies, there tends to be a fairly clear division between components, and an architecture in which one component is supported by another. The ground on which the stack rests is the hardware. Then come device drivers, for communicating with hardware, and a kernel of very low-level code to regulate who talks to the hardware and when. On top of that are usually several layers of operating-system facilities and utility programs, and on top of all of that are Firefox, iTunes and other consumer programs which the user has made a conscious decision to run. These top-level programs are visible, while the lower layers are concealed from the user and are generally very reliable, so it is easy to forget that they are there at all.

Similarly, when writing and testing a work with I7, it's easy to think that the only code running is the code directly generated by the source text. In fact, though, it runs inside a simulated computer called the virtual machine (or VM), and the VM has a software stack just as other computers do. Here the distinction between "program" and "operating system" is more blurred, because it can afford to be – the VM only ever has a single program running, and is not connected to any valuable hardware or data, so there is no need to protect the system's integrity from a malicious program, or to protect one program from the failings of another running at the same time. But there is still a recognisable software stack. From top to bottom, the VM at run-time contains:

(a) The rules, text and tables written by the author of this specific work of IF;
(b) Material contributed by Extensions which the author chose to borrow from;
(c) Rules, phrases and other constructions made by the Standard Rules extension, whose use is compulsory;
(d1) Infrastructure for rulebooks and code for maintaining a world model common to all works of IF;
(d2) The code needed to manage complex data structures such as relations, tables, indexed text, and so on;
(e) The interface to the VM, which is abstracted so that higher levels do not need to know whether Glulx or the Z-machine is being used.

Here (d1) and (d2) are independent blocks, so the picture is roughly so:

the player typing at a keyboard

(a) MATERIAL WRITTEN BY THE AUTHOR

(b) EXTENSIONS CHOSEN BY THE AUTHOR

(c) THE STANDARD RULES

(d1) MECHANICS OF PLAY (d2) DATA STRUCTURE SUPPORT

(e) VIRTUAL MACHINE INTERFACE

virtual machine "hardware"

NI is not like a compiler for a conventional program, because it has to conjure up the entire software stack whenever it compiles anything. (Until 2008, NI compiled code which ran on top of the traditional I6 library: nowadays it compiles stand-alone code which never uses the `#Include` directive. While it's true that the I6 compiler does add a very thin extra layer of code itself – the "veneer" – in all other respects NI specifies every single line of I6 code which makes up the eventual story file.)

NI compiles layers (a), (b) and (c) from the I7 source text found in the project file, in the Extensions installed by the user, and in the Standard Rules extension which comes pre-installed. But parts (d1), (d2) and (e) are almost exactly the same I6 code whatever may be sitting above them: they are simply copied, with minor variations, from a large body of standing code installed in the I7 application which is called the "template".

§**2. Segments and Paragraphs.** The template is divided into about 38 individual "segments", each stored in its own file and with the `.i6t` file extensions. This stands for "I6 template", because the code generated by NI is Inform 6 (I6) code. What makes the file a template rather than being raw code is that it is divided into named paragraphs which contain both commentary and also I6 code: when NI turns a template into the output code, the commentary (and each paragraph heading) is stripped out.

See the Inform documentation for how to modify the template in use for any particular project: I6 code can be added before, instead of or after any named segment or paragraph, and in addition, it's possible to replace entire segment files with your own versions stored in the Materials folder for a project.

§**3. Architecture.** To recap, then, the template contributes the following parts of the software stack:

(d1) MECHANICS OF PLAY (d2) DATA STRUCTURE SUPPORT

(e) VIRTUAL MACHINE INTERFACE

A more detailed version of this diagram organises its 38 segments follows:

NI Control. `Main.i6t`, `Types.i6t`, `Output.i6t`, `Definitions.i6t`.

Mechanics of Play I: Rules. `OrderOfPlay.i6t`, `Actions.i6t`, `Activities.i6t`, `Rulebooks.i6t`.

II: Infrastructure. `Parser.i6t`, `ListWriter.i6t`, `OutOfWorld.i6t`, `WorldModel.i6t`, `Light.i6t`, `Tests.i6t`.

III: Basic Services. `Language.i6t`, `MStack.i6t`, `Chronology.i6t`, `Printing.i6t`, `RTP.i6t`, `Utilities.i6t`.

Data Structure Support I: Basics. `Number.i6t`, `Time.i6t`, `Tables.i6t`, `Sort.i6t`, `Relations.i6t`, `Figures.i6t`.

II: Block Values. `IndexedText.i6t`, `RegExp.i6t`, `Char.i6t`, `UnicodeData.i6t`, `StoredAction.i6t`, `Lists.i6t`, `BlockValues.i6t`, `Flex.i6t`.

Virtual Machine Interface. `ZMachine.i6t` *or* `Glulx.i6t` and `FileIO.i6t`.

To elaborate:

NI Control. As well as containing commentary and I6 code, template files can also contain commands to tell NI to do something more interesting than simply copying over material verbatim into its output. Four of the segments use this ability a great deal: the remaining segments hardly use it at all. These four segments therefore don't fit anywhere in the diagram of the software stack above. "Main.i6t" controls the top-level logic of NI and gives the sequence of operations; "Types.i6t" specifies the basic kinds of value known to NI – numbers, times, texts, rulebooks and so on; "Output.i6t" is essentially the arrangement used to join all the many fragments of I6 from the template and the I7 source text into a single end-to-end I6 program which will become the story file; "Definitions.i6t" defines many named constants which are used across the template.

Mechanics of Play I: Rules. "OrderOfPlay.i6t" is the highest-level description of what happens when a story file runs: it contains the I6 `Main` routine, and definitions of the primitive rules in the most important rulebooks.

"Actions.i6t" and "Activities.i6t" contain code which runs actions and activities, respectively: these sit on top of "Rulebooks.i6t", which performs general rulebook-running.

Mechanics of Play II: Infrastructure. "Parser.i6t" breaks down a command typed by the player into a slate of variables which can be formed into an action. "ListWriter.i6t" is a general-purpose service for printing lists of objects satisfying various descriptions, and formatted in different ways. "OutOfWorld.i6t" provides code to handle out-of-world actions not needing direct access to VM internals: PRONOUNS and SUPERBRIEF, for instance. "Tests.i6t" provides code for the testing commands – TEST, ACTIONS, SHOWME and so forth.

"WorldModel.i6t" contains code for performing object movements and the like in such a way that the world model rules are preserved: it handles component parts, decides touchability and so on. "Light.i6t" determines the level of light and decides on visibility.

Mechanics of Play III: Basic Services. "Language.i6t" provides English-language messages issued by template routines and the Standard Rules during play: replacing this segment is the way to translate I7 story files into other languages of play. (It's the equivalent of the old I6 "language definition files", and retains most of the same structure.) "MStack.i6t" provides a small general-purpose memory stack. "Chronology.i6t"

performs the continuous monitoring required to ensure that past-tense conditions work: for instance we can only determine whether or not "the Black Door has been open" if we have spent the whole time so far checking on whether it is open or not, and this is where the checking is done. "Printing.i6t" handles paragraph-breaking, the printing of object names with suitable articles attached, and miscellaneous other printing needs. "RTP.i6t" issues run-time problem messages as needed: these should appear only if the story file does something clearly illegal, and point to bugs not yet removed from the author's code. "Utilities.i6t" provides miscellaneous utility functions at a very low level, such as for unsigned comparison of two numbers.

Data Structure Support I: Basics. Many kinds of value need no maintenance, and little or no support. "Number.i6t" and "Time.i6t" contain code to parse numbers and times of day from text typed by the player, together with a few basic operations: for instance, the rounding off of times of day. "Tables.i6t" provides access to table entries, specified in a variety of direct and indirect ways; this makes use of "Sort.i6t", which abstracts a choice of sorting algorithms for use on tables and other I6 data. "Relations.i6t" provides code for testing and asserting relations: the information about what is related to what else is stored in a variety of different ways, depending on the relation, to make best use of memory. "Figures.i6t" displays figures and plays back sound effects, or rather, passes instructions to do so down to the VM.

Data Structure Support II: Block Values. Kinds of value can be divided into the ordinary ones – number, object, time and so on – together with "block values" such as indexed text, stored action and list. Block values have to be stored in dynamically allocated memory from a heap. It would be wasteful to include all of this code, and to spare memory for the heap, if no block values were actually needed, so the following segments are only compiled if the source text makes specific reference to at least one block value. "IndexedText.i6t" manages character-indexed strings of text, which can shrink or stretch to arbitrary lengths: it makes use of "RegExp.i6t" for regular expression matching and search-and-replace; and also of "Char.i6t" for code to deal with lower and upper casing of letters, and "UnicodeData.i6t" to provide character set details, mechanically converted from the Unicode 4.0 standard. "StoredAction.i6t" manages stored actions: it can convert the current action into a stored one, and also try a long-stored action so that it now takes place. "Lists.i6t" manages the flexibly sized lists produced by values whose kind is list of numbers, list of texts, list of lists of lists of stored actions, and so forth: it can merge, insert, delete, resize, rotate, and reverse lists, and makes use once again of "Sort.i6t" (q.v.) to sort them.

"BlockValues.i6t" provides the basic support for kinds of value which are stored as blocks of memory on the heap.

At the lowest level, "Flex.i6t" manages flexible memory allocation as required by "BlockValues.i6t": it organises the heap of unclaimed memory, for instance, and maks allocations and deallocations when needed.

Virtual Machine Interface. Depending on the Settings used for the I7 project being compiled, we either use "ZMachine.i6t" or "Glulx.i6t": if Glulx, we also add "FileIO.i6t", which provides support for the limited file-handling abilities offered by Glulx.

Properly speaking, there is one further template file: "Introduction.i6t". It provides the commentary you are now reading, but has no other function, contains no code, and is finished now anyway.

Main Template B/maint

Purpose

The top-level logic of NI: the sequence of operations followed by NI up to the point where the output file is opened, resuming after it is closed again.

---

§**1. Startup.** This segment of the template is not like any other. It contains almost the complete logical sequence of operations followed by NI – indeed, NI essentially works by parsing some command-line arguments to set switches and then asking the template interpreter to run through "Main.i6t", the only template file which must always exist. (The other template files are only ever involved when called on by the `{-segment:...}` command from a template file already running.) Whereas most template segments contain I6 code to pass through into NI's output, this one runs both before and after NI's output file is being written, and contains only commands.

The Startup paragraph is not in fact modifiable in any easy way, because of course "Include..." sentences – used to tell the template interpreter to override the template files – will not be understood until long after this paragraph has been fully dealt with. But perhaps that's no bad thing.

```
{-callv:start_memory}
{-callv:start_lexer}
{-callv:make_reserved_words}
{-callv:handle_census_mode}
{-segment:Types.i6t}
{-callv:make_built_in_relations}
{-callv:make_built_in_verbs}
{-callv:make_built_in_determiners}
{-progress-stage:0}
{-log-phase:Lexical analysis}
{-callv:read_primary_source_text}
{-callv:create_kind_kind}
{-callv:create_standard_csps}
```

§**2. Semantic Analysis.** Similarly: Include... sentences are not read until this paragraph is long forgotten.

```
{-progress-stage:1}
{-log-phase:Semantic analysis I}
{-callv:plant_parse_tree} ! Initialise the parse tree
{-callv:break_source_into_sentences} ! Build first tranche of sentences
{-callv:traverse_for_extensions} ! Expand extension inclusions and build sentences
{-callv:satisfy_heading_dependencies}
{-callv:traverse_for_verbs} ! Find verbs in the assertion sentences
{-callv:traverse_for_plural_definitions} ! Build irregular plurals dictionary
{-callv:tidy_up_ofs_and_froms} ! More "of" wrangling
{-callv:register_recently_lexed_phrases} ! To make commands children of their routines
{-callv:declare_source_loaded}
{-callv:include_templates_for_types}
{-log-phase:Semantic analysis II}
{-callv:verify_parse_tree} ! Purely to check that NI is running correctly
{-callv:check_extension_versions} ! Do the extension version numbers meet needs?
{-callv:make_heading_tree} ! Stratify headings and subheadings
{-callv:write_headings_as_xml} ! Dump them to a file for the GUI to use
{-log-phase:Semantic analysis III}
{-callv:traverse_for_adjective_definitions}
{-callv:traverse_to_create_equations}
{-callv:traverse_to_create_tables}
{-callv:traverse_for_phrase_names}
```

§**3. Assertion Reading.** Since Include... sentences are read during pass 2, they might just be able to meddle by adding instructions to take place after this paragraph, but would be too late to work before or instead of it.

```
{-progress-stage:2}
{-log-phase:First pass through assertions}
{-read-assertions:1}
{-log-phase:All objects and properties now created}
{-callv:log_brief_picture}
{-log-phase:Second pass through assertions}
{-read-assertions:2}
```

§**4. Model Construction.**

```
{-log-phase:Making the model world}
{-callv:Inform_name_the_actions}
{-callv:Inform_name_the_objects}
{-callv:make_model_world}
{-callv:validate_definitions}
{-callv:make_further_built_in_relations}
```

§5. Tables and Grammar.

```
{-log-phase:Tables and grammar}
{-callv:check_tables_for_kind_clashes}
{-callv:traverse_to_stock_tables}
{-callv:traverse_to_stock_equations}
{-callv:traverse_for_grammar}
```

§6. Phrases and Rules.

```
{-progress-stage:3}
{-log-phase:Phrases and rules}
{-callv:define_named_printing_phrases}
{-log-phase:Phrases and rules A}
{-callv:traverse_for_phrases}
{-log-phase:Phrases and rules B}
{-callv:register_phrase_meanings}
{-log-phase:Phrases and rules C}
{-callv:parse_rule_parameters}
{-log-phase:Phrases and rules D}
{-callv:add_rules_to_rulebooks}
{-log-phase:Phrases and rules E}
{-callv:parse_rule_placements}
{-callv:empty_all_headings}
```

§**7. Code Generation.** This is where we hand over to regular template files – containing code passed through as I6 source, as well as a few further commands – starting with "Output.i6t".

```
{-progress-stage:4}
{-log-phase:Code generation}
{-open-file}{-segment:Output.i6t}{-close-file}
{-log-phase:Compilation now complete}
```

§8. Metadata.

```
{-callv:write_ifiction_and_blurb}
```

§**9. Indexing.** This paragraph can be skipped without harming any of the rest of NI's work: the only effect is to suppress the generation of the index. (Indeed, if NI is called with the `-noindex` command-line switch, then the template interpreter ignores all commands in between `{-open-index}` and `{-close-index}`, thus skipping exactly this paragraph.)

```
{-open-index}
{-index:Phrasebook Index=A guide to the phrases allowed; [LEXICON]a lexicon of words; a [RELTABLE]table
of relations, and [VERBTABLE]of verbs.|What are phrases?<PHRASES>; And descriptions?<DESCRIPTIONS>; Relations?<RELA
Verbs?<VERBS>=John Florio's Italian-English dictionary of 1598-1611}
    {-callv:index_page_Phrasebook}
{-index:Kinds Index=Table of all the kinds; [ARITHMETIC]how arithmetic affects them; and [KDETAILS]details
of each kind in turn.|What are kinds?<KINDS>; More about kinds of object<NEWKINDS>; And kinds of value<KINDSVALUE>=
medieval bestiary, showing every kind of animal}
    {-callv:index_page_Kinds}
{-index:World Index=A map of the geographical layout; [MDETAILS]contents of each room; and [LEXICON]an
A to Z of rooms and things.|What's the map?<MAP>; Using regions<REGIONS>; If the map looks wrong...<MAPHINTS>;
Exporting to EPS<EPSMAP>=William Smith's first geological map of England, 1815}
    {-callv:index_page_World}
{-index:Actions Index=The actions (click magnifiers for details); [NAP]kinds of action; [COMMANDS]commands
A to Z; [LEXICON]actions A to Z; [ARULES]the applicable rules.|What are actions?<ACTIONS>; Creating new
actions<NEWACTIONS>; Out of world actions (in red)<OUTOFWORLD>=Standard English men-at-work icon, used
on road signs}
    {-callv:index_page_Actions}
{-index:Rules Index=Rules not directly tied to actions (see the Actions Index) or scenes (the Scenes
Index).|What are rulebooks?<RULEBOOKS>; What are activities?<ACTIVITIES>; Moving or abolishing rules<RLISTING>=Baby
tablet of the Laws of Hammurabi, c.1760 BC}
    {-callv:index_page_Rules}
{-index:Contents Index=Headings and [EXTLIST]extensions; [NAMES]named values, Tables and so on; the [LCARD]Library
Card; the [STORYFILE]story file.|How do headings work?<HEADINGS>; What's the Library Card?<LCARDS>=The
first Gutenberg printing press in action, c.1455}
    {-callv:index_headings}
    {-callv:index_extensions}
    {-callv:update_census_of_extensions}
    {-callv:index_quantities}
    {-callv:index_tables}
    {-callv:index_equations}
    {-callv:index_figures}
    {-callv:index_sounds}
    {-callv:index_external_files}
    {-callv:index_library_card}
{-index:Scenes Index=A map of how the scenes begin and end; and [SDETAILS]details of each scene in turn.|What
are scenes?<SCENESINTRO>; How they link together<LINKINGSCENES>=Strolling beside a riverside theatre
in 18th century London}
    {-callv:index_page_Scenes}
{-callv:complete_index}
{-close-index}
```

§**10. Shutdown.** Closing the problems report, making any final reports to the debugging log, and freeing all allocated memory: and that's then it.

```
{-callv:report_unacted_upon_interventions}
{-callv:complete_problems_report}
{! -callv:report_pairs_observed}
{! -callv:report_pairs_allowed}
{! -callv:debug_memory_statistics}
{! -callv:debug_parser_statistics}
{! -callv:debug_verbs}
{-callv:free_memory}
```

Types Template B/typet

Purpose

To set up the atomic kinds of value (the base data types, in other words) within NI.

---

§**1. Header.** The following mass of type definitions is not heavily subdivided into paragraphs since it's read so early in NI's run that "Include..." sentences haven't had time to be read yet – so they aren't easy to customise. (Except by putting a whole customised version of the file into the relevant `Materials/I6T` folder.)

The `{-lines:type}` command causes all subsequent lines to be sent as parameters to the `{-type:...}` command, until the next `{-endlines}` command.

```
{-callv:make_type_IDs_table}
{-lines:type}
#DEFAULTS:

```

§**2. Macros.** New kinds of value cause some I7 source to be generated, following various combinations of the macros below.

```
*UNDERSTOOD-VARIABLE:
<type> understood is a <type> which varies.
*END

*PRINTING-ROUTINE:
To say (value - <type>):
    (- print (<printing-routine>) {value}; -).
*END

*PRINTING-ROUTINE-BLOCK:
To say (value - <type>):
    (- print (<printing-routine>) {-pointer-to:value}; -).
*END

*RANDOM-CHOOSERS:
To decide which <type> is a random <lower-case-type> between (first value - <type>) and (second value
- <type>) - <type-number>:
    (- R_<printing-routine>({first value}, {second value}) -).
To decide which <type> is a random <lower-case-type> from (first value - <type>) to (second value - <type>)
- <type-number>:
    (- R_<printing-routine>({first value}, {second value}) -).
*END

*ENUMERATION-CHOOSERS:
To decide which <type> is <lower-case-type> after (X - <type>) - <type-number>:
    (- A_<printing-routine>({X}) -).
To decide which <type> is <lower-case-type> before (X - <type>) - <type-number>:
    (- B_<printing-routine>({X}) -).
To decide which <type> is a random <lower-case-type> - <type-number>:
    (- R_<printing-routine>() -).
*END
```

§**3. Group 1.** These are data types used in type-checking but not representing specific kinds of value at run-time.

The + notation indicates a type name which NI requires us to construct, and with this specific name.

```
+ANY_VALUE_TY:
description:a value
singular:value
plural:values
constant-compilation-method:none
cast:<all>
! Matches any value

+ASSIGNABLE_VALUE_TY:
description:a value
singular:assignable-value
plural:assignable-values
constant-compilation-method:none
cast:<assignable>
! Matches any value which can be the rvalue of an assignment

ANY_POINTER_VALUE_TY:
```

```
description:a value
singular:pointer value
constant-compilation-method:none
cast:<pointer>
! Matches any value where the I6 representation is a pointer to a block

ANY_WORD_VALUE_TY:
description:a value
singular:word value
constant-compilation-method:none
cast:<word>
! Matches any value where the I6 representation is a single word

+KIND_OF_POINTER_VALUE_TY:
description:the name of a kind of complex value
singular:kind of pointer value
constant-compilation-method:none
! Matches name of kind of value pointing to a block, compiles to NI type number

+KIND_OF_WORD_VALUE_TY:
description:the name of a kind of simple value
singular:kind of word value
constant-compilation-method:none
! Matches name of kind of value in a single word, compiles to NI type number

CLASSIFIED_TY:
description:some text or the name of a room, thing or rule
singular:miscellaneous-value
plural:miscellaneous-values
used-in-let-with-cast-priority:50
constant-compilation-method:none
cast:OBJECT_TY
cast:TEXT_TY
cast:TEXT_ROUTINE_TY
cast:RULE_TY
! Deprecated: a union of the four I6-metaclass-distinguishable data types

+VALUE_DESCRIPTION_TY:
description:a description of values
singular:domain-description
plural:domain-descriptions
constant-compilation-method:special
! Used only in type-checking to distinguish value from object descriptions

TEMPLATE_VAR1_TY:
is-template-variable:yes
template-variable-number:1
description:template variable 1
singular:kov marker 1
plural:kov marker 1s
! Used in template matches

TEMPLATE_VAR2_TY:
is-template-variable:yes
template-variable-number:-1
description:template variable 1 reference
singular:kov reference 1
plural:kov reference 1s
! Used in template matches
```

```
TEMPLATE_VAR3_TY:
is-template-variable:yes
template-variable-number:2
description:template variable 2
singular:kov marker 2
plural:kov marker 2s
! Used in template matches
TEMPLATE_VAR4_TY:
is-template-variable:yes
template-variable-number:-2
description:template variable 2 reference
singular:kov reference 2
plural:kov reference 2s
! Used in template matches
+NO_ENTRIES_TY:
description:no entries
constant-compilation-method:none
! Used for the type of the empty list { }
```

§**4. Group 2.** Data types for basic word-sized values.

```
+NUMBER_TY:
description:a number
documentation-reference:kind_number
singular:number
plural:numbers
quasinumerical:yes
has-i6-GPR:yes
explicit-i6-GPR:DECIMAL_TOKEN
i6-printing-routine-actions:DA_Number
used-in-let-with-cast-priority:10
can-be-type-of-global-variable:yes
uses-signed-comparisons:yes
can-exchange:yes
default-value:0
index-default-value:0
specification-text:Whole number in the range -32768, -32767, ..., -2, -1, 0, 1, 2, 3, ..., 32767: small
numbers can be written textually as 'one', 'two', 'three', ..., 'ten', 'eleven', 'twelve'. (A much larger
number range is allowed if we compile the source to Glulx rather than the Z-machine: see the Settings
panel.)
index-priority:1
constant-compilation-method:literal
+TIME_TY:
description:a time
documentation-reference:kind_time

can-be-type-of-global-variable:yes
uses-signed-comparisons:yes
can-exchange:yes
```

```
default-value:540
loop-domain-schema:for (*1=0: *1<TWENTY_FOUR_HOURS: *1++)
has-i6-GPR:yes
explicit-i6-GPR:TIME_TOKEN
i6-printing-routine:PrintTimeOfDay
i6-printing-routine-actions:PrintTimeOfDay
specification-text:A time of day, written in the form '2:34 AM' or '12:51 PM', or a length of time such
as '10 minutes' or '3 hours 31 minutes', which must be between 0 minutes and 23 hours 59 minutes inclusive.
index-default-value:9:00 AM
index-priority:1
constant-compilation-method:literal
apply-template:*PRINTING-ROUTINE

+TEXT_TY:
description:some text
singular:text
plural:texts
used-in-let-with-cast-priority:30
can-be-type-of-global-variable:yes
default-value:EMPTY_TEXT_VALUE
i6-printing-routine:PrintText
index-default-value:""
specification-text:Some text in double quotation marks, perhaps with substitutions written in square
brackets.
index-priority:3
cast:TEXT_ROUTINE_TY
sometimes-cast:CLASSIFIED_TY
constant-compilation-method:special
! Because of casting, this can be text either with or without substitutions

+OBJECT_TY:
description:an object
singular:object
plural:objects
used-in-let-with-cast-priority:40
can-be-type-of-global-variable:yes
default-value:nothing
index-default-value:nothing
index-priority:2
i6-printing-routine:PrintShortName
i6-printing-routine-actions:DA_Name
sometimes-cast:CLASSIFIED_TY
constant-compilation-method:special
specification-text:Objects are values intended to simulate physical things: places, people, things, and
so on. They come in many kinds. The special value 'nothing' is also allowed, and can be used to mean
'no object at all'.
! For any single specific object (direction, room, thing, etc.), or "nothing"

+TEXT_ROUTINE_TY:
description:some text with substitutions
singular:text-routine
plural:text-routine
sometimes-cast:CLASSIFIED_TY
constant-compilation-method:special
! Quoted text which certainly does contain substitutions
```

```
+QUOT_TY:
description:some formatted text without substitutions
singular:boxed-quotation
plural:boxed-quotations
constant-compilation-method:special
! Quoted text used only for I6 box quotation statements, without substitutions
+SNIPPET_TY:
description:a snippet
documentation-reference:kind_snippet
singular:snippet
plural:snippets
can-be-type-of-global-variable:yes
default-value:101
index-default-value:<i>word 1 of command</i>
specification-text:A fragment of the player's most recent typed command, taking in a run of consecutive
words.
index-priority:5
i6-printing-routine:PrintSnippet
constant-compilation-method:none
apply-template:*PRINTING-ROUTINE
! Numerical reference to a word range (indicated by word counts) in the command
+UNICODECHAR_TY:
description:a Unicode character
singular:unicode-character
plural:unicode-characters
constant-compilation-method:literal
! For constants like "unicode 65" or "unicode black knight chess piece" only
+OBJECT_DESCRIPTION_TY:
description:a description
documentation-reference:kind_description
singular:description
plural:descriptions
used-in-let-without-casts:yes
can-be-type-of-global-variable:yes
default-value:Prop_Falsity
index-default-value:<i>matching nothing</i>
index-priority:5
constant-compilation-method:special
specification-text:A description of objects - say, 'animals which are in closed containers' - may not
look like a value, but it is. Writing 'the number of visible women', for instance, actually applies the
phrase 'number of...' to the value 'visible women', this being a description. (We very rarely need to
know this, but occasionally it's useful to store descriptions or do other value-related things with them.)
! Routine determining whether its argument is an object matching a description
+USEOPTION_TY:
description:the name of a use option
singular:use-option
plural:use-options
constant-compilation-method:special
! Constants only: the name of a use option, stored as its internal number
+PROPERTY_TY:
description:a property of something
singular:property
```

```
plural:properties
constant-compilation-method:special
unassignable:yes
! Used for names of properties such as "closed" or "carrying capacity"
+RULE_TY:
description:the name of a rule
documentation-reference:kind_rule
singular:rule
plural:rules
used-in-let-with-cast-priority:60
can-be-type-of-global-variable:yes
default-value:LITTLE_USED_DO_NOTHING_R
i6-printing-routine:RulePrintingRule
index-default-value:the little-used do nothing rule
sometimes-cast:CLASSIFIED_TY
cast:RULEBOOK_TY
constant-compilation-method:special
apply-template:*PRINTING-ROUTINE
specification-text:One of many, many rules which determine what happens during play. Rules can be triggered
by scenes beginning or ending, by certain actions, at certain times, or in the course of carrying out
certain activities.
indexed-grey-if-empty:yes
! Routine to test if a rule applies and carry it out if so
RULE_OUTCOME_TY:
description:a rule outcome
singular:outcome
plural:outcomes
constant-compilation-method:none
apply-template:*PRINTING-ROUTINE
! Used fleetingly to handle return values from rules (success, failure, none)
+RULEBOOK_TY:
modifying-adjective:action-based
modifying-adjective:object-based
description:the name of a rulebook
documentation-reference:kind_rulebook
singular:rulebook
plural:rulebooks
can-be-type-of-global-variable:yes
default-value: 0
loop-domain-schema:for (*1=0: *1<NUMBER_RULEBOOKS_CREATED: *1++)
index-default-value:the action-processing rules
constant-compilation-method:special
i6-printing-routine:RulePrintingRule
specification-text:A list of rules to follow, in sequence, to get something done. A rulebook is like
a ring-binder, with the individual rules as sheets of paper. Inform normally sorts these into their 'natural'
order, with the most specific rules first, but it's easy to shuffle the pages if you need to. When some
task is carried out during play, Inform is normally working through a rulebook, turning the pages one
by one.
indexed-grey-if-empty:yes
! A list of rules to be followed in sequence
+RULEBOOK_OUTCOME_TY:
description:the name of a rulebook outcome
```

```
singular:rulebook-outcome
plural:rulebook-outcomes
i6-printing-routine:RulebookOutcomePrintingRule
constant-compilation-method:special
apply-template:*PRINTING-ROUTINE
! Used to handle return values from rulebooks, which can be named and varied

+ACTION_NAME_TY:
description:an action name
documentation-reference:kind_actionname
singular:action-name
plural:action-names
can-be-type-of-global-variable:yes
default-value:##Wait
index-default-value:waiting action
constant-compilation-method:special
i6-printing-routine:SayActionName
apply-template:*PRINTING-ROUTINE
specification-text:An action is what happens when one of the people in the simulated world decides to
do something. A full action would be something like 'dropping the box', but an action name is just the
choice of which sort of thing is being done: here, it's 'the dropping action'. (Action names are always
written with the word 'action' at the end, to make sure they aren't mistaken for full actions.)
! To refer to an action in abstract, without any of the nouns it applies to

+ACTIVITY_TY:
description:an activity
documentation-reference:kind_activity
singular:activity
plural:activities
constant-compilation-method:special
can-be-type-of-global-variable:yes
used-in-let-with-cast-priority:80
default-value:PRINTING_THE_NAME_ACT
index-default-value:printing the name
specification-text:An activity is something which Inform does as part of the mechanics of play - for
instance, printing the name of an object, which Inform often has to do. An activity can happen by itself
('printing the banner text', for instance) or can be applied to an object ('printing the name of something',
say).
! The name of an activity, stored as its internal number

+SCENE_TY:
description:a scene
documentation-reference:kind_scene
singular:scene
plural:scenes
named-values-created-with-assertions:yes
can-be-type-of-global-variable:yes
used-in-let-with-cast-priority:80
default-value: 0
loop-domain-schema:for (*1=1: *1<=NUMBER_SCENES_CREATED: *1++)
index-default-value:the Entire Game
index-priority:2
i6-printing-routine:PrintSceneName
constant-compilation-method:quantitative
apply-template:*PRINTING-ROUTINE
```

```
specification-text:Like a scene in a play: a period of time which is usually tied to events in the plot. Scenes are created by sentences like 'Midnight Arrival is a scene.'
indexed-grey-if-empty:yes
! Scenes, as numbered in sequence in order of creation (from 0 not 1)

+TABLE_TY:
description:the name of a table
documentation-reference:kind_tablename
singular:table-name
plural:table-names
used-in-let-with-cast-priority:70
can-be-type-of-global-variable:yes
default-value:TheEmptyTable
loop-domain-schema:for (*2=0, *1=TableOfTables-->*2: *1: *2++, *1=TableOfTables-->*2)
index-default-value:<i>a table with no rows or columns</i>
i6-printing-routine:PrintTableName
constant-compilation-method:special
apply-template:*PRINTING-ROUTINE
specification-text:Like tables of information in a book or newspaper, tables in Inform hold values which have been organised into rows and columns. A table-name is just a single value, identifying which table is meant - say, 'Table of US Presidents' might be a table-name value.
indexed-grey-if-empty:yes
! Tables, stored as their array addresses inside the virtual machine

+TABLE_COLUMN_TY:
description:the name of a column
singular:table-column
plural:table-columns
constant-compilation-method:special
! Constants only: a table column name, by which its kind of value can be known

+EQUATION_TY:
description:the name of an equation
singular:equation-name
plural:equation-names
used-in-let-with-cast-priority:70
can-be-type-of-global-variable:yes
default-value:0
index-default-value:<i>an equation doing nothing</i>
i6-printing-routine:DA_Number
apply-template:*PRINTING-ROUTINE
constant-compilation-method:special
specification-text:Like formulae in a textbook or a scientific paper, equations in Inform are written out in displayed form and given names.
indexed-grey-if-empty:yes
! Equations, not stored at run-time

+RELATION_TY:
description:a relation
singular:abstract-relation
plural:abstract-relations
constant-compilation-method:special
! Constants only: a relation name, stored as its index in a run-time table

+UNDERSTANDING_TY:
description:a topic
singular:topic
```

```
plural:topics
i6-printing-routine-actions:DA_Topic
cast:TEXT_TY
cast:TEXT_ROUTINE_TY
constant-compilation-method:special
! I6 general parsing routine to match some specified text
+FIGURENAME_TY:
description:the name of a figure
documentation-reference:kind_figurename
singular:figure-name
plural:figure-names
can-be-type-of-global-variable:yes
used-in-let-with-cast-priority:80
default-value:1
loop-domain-schema:for (*2=0, *1=TableOfFigures-->*2: *1: *2++, *1=TableOfFigures-->*2)
index-default-value:figure of cover
constant-compilation-method:literal
i6-printing-routine:PrintFigureName
apply-template:*PRINTING-ROUTINE
specification-text:When made with the Glulx setting, an Inform project can include images as well as
words, and these are called figures. A figure-name is just the name of one of the figures in the current
project.
indexed-grey-if-empty:yes
! Blorb resource ID number for a picture
+SOUNDNAME_TY:
description:the name of a sound effect
documentation-reference:kind_soundname
singular:sound-name
plural:sound-names
can-be-type-of-global-variable:yes
used-in-let-with-cast-priority:80
constant-compilation-method:literal
default-value:0
loop-domain-schema:for (*2=0, *1=TableOfSounds-->*2: *1: *2++, *1=TableOfSounds-->*2)
index-default-value:<i>a silent non-sound</i>
i6-printing-routine:PrintSoundName
apply-template:*PRINTING-ROUTINE
specification-text:When made with the Glulx setting, an Inform project can include sound effects or pieces
of music. A sound-name is just the name of one of these sounds in the current project.
indexed-grey-if-empty:yes
! Blorb resource ID number for a sound effect
+EXTERNALFILE_TY:
description:the name of a file
documentation-reference:kind_externalfile
singular:external-file
plural:external-files
can-be-type-of-global-variable:yes
used-in-let-with-cast-priority:80
default-value:0
loop-domain-schema:for (*2=0, *1=TableOfExternalFiles-->*2: *1: *2++, *1=TableOfExternalFiles-->*2)
index-default-value:<i>a non-file</i>
constant-compilation-method:special
i6-printing-routine:PrintExternalFileName
```

```
apply-template:*PRINTING-ROUTINE
specification-text:When made with the Glulx setting, an Inform project can make limited use of files
stored on the computer which is operating the story at run-time. An external-file is just the name of
one of these files (not the filename in the usual sense, but a name given to it in the Inform source
text).
indexed-grey-if-empty:yes
! Address of an array holding a file I/O structure managed at run-time

+TRUTH_STATE_TY:
description:something which is either true or false
documentation-reference:kind_truthstate
singular:truth state
plural:truth states
can-be-type-of-global-variable:yes
default-value:false
index-default-value:false

§7. Tail.

```
{-endlines}
{-callv:complete_type_IDs_table}
```

Output Template B/outt

Purpose

This is the superstructure of the file of I6 code output by NI: from ICL commands at the top down to the signing-off comments at the bottom.

---

§**1. ICL Commands.** The Inform Control Language is a mini-language for controlling the I6 compiler, able to set command-line switches, memory settings and so on. I6 ordinarily discards lines beginning with exclamation marks as comments, but at the very top of the file, lines beginning `!%` are read as ICL commands: as soon as any line (including a blank line) doesn't have this signature, I6 exits ICL mode. So, basically, we'd better do this here:

```
{-call:compile_icl_commands}
```

§**2. Other Configuration.** Setting the `Grammar__Version` constant is a rather creaky old way to tell the I6 compiler to use more detailed grammar tables: GV1 has not in fact been used since about 1994.

```
Constant Grammar__Version 2;
```

§**3. Identification.** Both of the compiler and template layer, and of the story file to be produced.

The "library" identifying texts are now a little anachronistic, since the template layer is not strictly speaking an I6 library in the same way as the original: but it is surely the spiritual successor to 6/11N, so we may as well mark it 6/12N.

```
! This file was compiled by Inform 7: the build number and version of the
! I6 template layer used are as follows.
{-call:compile_build_number}
Constant LibSerial = "080126";
Constant LibRelease = "6/12N";
Constant LIBRARY_VERSION = 612;
{-array:UUID_ARRAY}
{-call:compile_bibliographic_i6_constants}
Default Story 0;
Default Headline 0;
{-routine:ShowExtensionVersions}
```

§**4. Use options.** Use options are translated into I6 constant declarations, and NI puts them here:

```
{-call:compile_use_options}
```

§**5. Constants.**

```
{-segment:Definitions.i6t}
```

§**6. Global Variables.** These are not the only global variables defined in the template layer: those needed locally only by single sections (and not used in definitions of phrases in the Standard Rules, or referred to by NI directly) are defined within those sections – they can be regarded as unimportant implementation details, subject to change at whim. The variables here, on the other hand, are more important to understand.

(1) The first three variables to be defined are special in that they are significant to very early-style Z-machine interpreters, where they are used to produce the status line display (hence `sline1` and `sline2`). The first variable must always equal a valid object number, which is why we – pretty weirdly – set it equal to the placeholder object `InformLibrary`, which takes no part in play, and is not a valid I7 object. This is not typesafe in I7 terms, but that doesn't matter because initialisation will correct it to a typesafe value before any I7 source text can execute. (`sline1` and `sline2` are entirely unused on when we target Glulx.) Once these variables are defined, the sequence of definition of the rest is not significant.

(2) The `say__*` are used for the finite state machine used in printing text, which keeps track of automatic paragraph breaking and the like. For details see the "Printing.i6t" section. For `subst__v`, see the explanation of "substitution-variable" in the Standard Rules. The variables `ct_0` and `ct_1` hold the current choice of table and table row, respectively, but in some ways these global variables are misleading: in very many routines, `ct_0` and `ct_1` are defined as local variables, and it's the local definitions which take precedence. (The global variables allow table-selecting code to compile in routines where it isn't possible to define these locals because no stack frame exists.)

(3) `standard_interpreter` is used only for the Z-machine VM, and is always 0 for Glulx. For Z, a non-zero value here is the version number of the *Z-Machine Standards Document* which the interpreter claims to support, in the form (upper byte).(lower). `undo_flag`, similarly, behaves slightly differently on the two platforms according to whether they support multiple consecutive UNDOs. UNDO basically works by taking memory snapshots of the whole VM ("saving UNDO") to revert to at a later point ("performing UNDO"), so it is expensive on memory, and traditional VMs can only store a single memory snapshot – making two UNDOs in a row, going back two steps, impossible. Given this, `undo_flag` has three possible states: 0 means UNDO is not available at all, 1 means it is not available now because there is no further saved state to go back to from here, and 2 means it is available.

(4) `deadflag` in normally 0, or false, meaning play continues; 1 means the game ended in death; 2 for ended in victory; higher numbers represent exotic endings. `deadflag` switching state normally triggers an end to rulebook processing, so is the single most important global variable to the running of a story file.

(5) At present, `time_rate` is not made use of in I7: if positive, it is the number of minutes which pass each turn; if negative, the number of turns which pass each minute. This is quite a neat way to approximate a wide range of time steps with an integer such that fractions are exact and we can approximate any duration to a fair accuracy (the worst case being 3/4 minute, where we have to choose between 1 minute or 1/2 minute).

(6) Note that `notify_mode` is irrelevant if the use option "Use no scoring" is in force: it isn't looked at, and can't be changed, and shouldn't have an effect anyway since `score` will never be altered.

(7) `player` is a variable, not a constant, since the focus of play can change. `SACK_OBJECT` is likewise an unexpected variable: in the I6 library, there could only be one player's holdall, a single rucksack-like possession which had to be the value of the constant `SACK_OBJECT`. Here we define `SACK_OBJECT` as a global variable instead, the value of which is the player's holdall currently in use. `visibility_ceiling` is the highest object in the tree visible from the player's point of view: usually the room, but sometimes nothing (in darkness), and sometimes a closed non-transparent container.

(8) See "OrderOfPlay.i6t" for the meaning of action variables.

(9) This is a slate of global variables used by the parser to give some context to the general parsing routines (GPRs) which it calls; in the I6 design, any object can provide its own GPR, in the form of a `parse_name` property. GPRs are in effect parser plug-ins, and I7 makes extensive use of them.

(10) Similarly, variables for the parser to give context to another sort of plug-in routine: a scope filter. I7 uses these too.

(11) The `move_*` variables are specific to the `##Going` action.

(12) These variables hold current settings for listing objects and, more elaborately, performing room descriptions.

(13) The current colour scheme is stored in variables in order that it can be saved in the save game state, and changed correctly on an UNDO: if it were a transient state inside the VM interpreter's screen model, then a RESTORE or UNDO will upset what the original author may have intended the appearance of text in particular scenes to be. (Cf. Adam Cadre's I6 patch `L61007`.)

(14) These pixel dimensions are used both for the Glulx and v6 Z-machines, but not for the more commonly used versions 5 or 8, whose screen model is based on character cells.

(15) Parameters used by `LibraryMessages`: this may be replaced later.

(16) For debugging. `debug_flag` is traditionally called so, but is actually now a bitmap of flags for tracing actions, calls to object routines, and so on.

§**7. VM-Specific Code.** These sections of code contain different definitions of the same routines, and in some cases the same arrays, to handle low-level functions in the virtual machine – saving the game, performing UNDO, parsing typed text into dictionary word addresses and so on.

```
#Ifdef TARGET_GLULX;
{-segment:Glulx.i6t}
#Endif;
#Ifdef TARGET_ZCODE;
{-segment:ZMachine.i6t}
#Endif;
```

§**8. Compass.** I6 identified compass directions as being children of the pseudo-object `Compass`; I7 uses membership of the class `CompassDirection` instead. We need both ways here. (Note that `Compass` is not a valid I7 object, and is used for no other purpose.) Because of the traditional structure of language definitions, this needs to come first.

```
Class CompassDirection
with capacity 0, article "the", description [; L__M(##Look, 7, self); ],
has scenery;
Object Compass "compass" has concealed;
```

§**9. Language of Play.** The equivalent of I6's language definition file, though here the idea is that a translation should have an inclusion to replace the "Language.i6t" segment, which contains the English definition.

```
{-segment:Language.i6t}
Default LanguageCases 1;
#Ifndef LibraryMessages; Object LibraryMessages; #Endif;
```

§**10. The Old Library.** The I6 library consisted essentially of the parser, the verb routines, and a pile of utilities and world-modelling code, of which the biggest single component was the list-writer. The parser lives on below; the verb routines are gone, with the equivalent functionality having moved upstairs into I7 source text in the Standard Rules; and the rest of the library largely lives here:

```
{-segment:Light.i6t}
{-segment:ListWriter.i6t}
{-segment:Utilities.i6t}
```

§**11. Parser.** The largest single block of code in the traditional I6 library part of the template layer is the parser.

The two pseudo-objects `InformParser` and `InformLibrary` are relics of the object-oriented approach in I6, and are used only very slightly in the template layer; they are not used at all in I7, and are not valid for the "object" kind of value.

The parser includes arrays for typed text and some parsing information derived from it, and if these should overrun it would cause enigmatic bugs, as the next arrays in memory would be corrupted: as a tripwire, the `Protect_I7_Arrays` array consists of two magic values in sequence. If it is ever discovered to contain the wrong data, the alarm sounds.

```
Object InformParser "(Inform Parser)" has proper;
{-segment:Parser.i6t}
[ ParserError error_type;
    if (error_type ofclass String or Routine) PrintSingleParagraph(error_type);
    rfalse;
];
Object InformLibrary "(Inform Library)" has proper;
Array Protect_I7_Arrays --> 16339 12345;
```

§**12. Order of Play.** The `Main` routine, where execution begins, and the primitive rules in the principal rulebooks.

```
{-segment:OrderOfPlay.i6t}
```

§**13. Properties.** Some either/or properties are compiled to I6 attributes, which must be predeclared, so we do that first. (All other properties can simply be used without declaration.)

What then follows is a table of property metadata: in particular, specifying which properties can be used with which I6 classes or objects. Policing this at run-time costs a little speed, but traps many errors of programming, and keeps everything typesafe. It is the price we pay for the relatively lenient compile-time checking of I7's "object" kind of value. To make it as efficient as possible, we calculate offsets into the metadata: this has to be done (once) at run-time, with the routine compiled.

```
{-call:compile_attributes}
{-array:property_metadata}
Array attribute_offsets --> (50 + {-value:NUMBER_CREATED(property_name)});
Array property_offsets --> (100 + {-value:NUMBER_CREATED(property_name)} + INDIV_PROP_START-48);
{-routine:CreatePropertyOffsets}
```

§**14. Quantities.** Some of these are constants – the enumerated values of new kinds of value with names as values – while others are non-local variables in I7. NI can choose to translate an I7 variable into any I6 lvalue, and usually makes this an entry in an array called `Global_Vars` rather than an I6 global variable: the latter are limited in number, the former are not.

```
{-call:declare_quantities}
{-array:Global_Vars}
```

§**15. Activities.** These are numbered upwards from 0 in order of creation. The following arrays taken together provide, for each activity number: (i) the rulebook numbers for the before, for, and after stages of the activity, and (ii) a flag indicating whether the activity is "future action"-capable, that is, is a parsing activity allowed to make use of the action which conjecturally might result from the current grammar line being parsed. (This is called the "action to be", hence "atb".)

```
Constant NUMBER_RULEBOOKS_CREATED = {-value:NUMBER_CREATED(rulebook)};
{-call:compile_activity_constants}
{-array:Activity_before_rulebooks}
{-array:Activity_for_rulebooks}
{-array:Activity_after_rulebooks}
{-array:Activity_atb_rulebooks}
```

§**16. Relations.**

```
{-array:relation_metadata}
{-call:compile_defined_relations}
```

§**17. Printing Routines.**

```
{-call:compile_data_type_support_routines}
{-routine:I7_Kind_Name}
{-routine:RulebookOutcomePrintingRule}
```

§**18. Object Tree.** The I6 object tree contains `Class` definitions as well as objects, but we precede both with a pseudo-object called `property_numberspace_forcer`. It does nothing except to ensure that properties are declared in I6 in the same sequence as I7 (which need not otherwise happen); it plays no part in play, and is not a valid I7 "object" value.

```
{-log:Compiling the object tree}
{-call:compile_property_numberspace_forcer}
{-call:compile_object_tree}
{-call:compile_direction_object_constants}
{-call:compile_runtime_relation_storage}
```

§**19. Tables.** The initial state of the I6 arrays corresponding to each I7 table: see "Tables.i6t" for details.

```
{-log:Compiling the tables}
{-call:compile_tables}
```

§**20. Equations.** Routines to evaluate from equations.

```
{-log:Compiling the equations}
{-call:compile_equations}
```

§**21. Actions.**

```
{-log:Compiling the named action patterns}
{-call:compile_named_action_patterns}
{-log:Compiling the action routines}
{-array:ActionData}
{-array:ActionCoding}
{-array:ActionHappened}
{-call:compile_action_routines}
{-routine:MistakeActionSub}
```

§**22. Phrases.** The following innocent-looking commands tell NI to compile I6 definitions for all of the non-inline "To..." phrases, and all of the rules which are not I6-written primitives, so it results in a fairly enormous cataract of code.

```
{-log:Compiling the phrases}
{-call:compile_phrases}
{-call:compile_adjectival_phrases}
{-call:compile_list_together_routines}
{-call:compile_los_routines}
```

§**23. Timed Events.** Some of the phrases are simply called in the course of other phrases, but some are rules in rulebooks or in the table of timed events, so those come next:

```
{-array:TimedEventsTable}
{-array:TimedEventTimesTable}
```

§**24. Rulebooks.** The literally hundreds of rulebooks are set up here. (In the end a rulebook is only a (word) array of rule addresses, terminated with a `NULL`.)

```
{-log:Compiling the rulebooks}
{-array:rulebooks_array}
{-call:compile_rulebooks}
{-call:resolve_predeclared_booked_rules}
```

§**25. Scenes.**

```
{-log:Compiling scene details}
{-routine:DetectSceneChange}
{-routine:PrintSceneName}
#IFDEF DEBUG;
{-routine:ShowSceneStatus}
#ENDIF;
```

§**26. The New Library.** The gleaming, aluminium and glass extension to the library: almost all of it material new in I7 usage.

```
{-log:CTNL}
{-segment:Actions.i6t}
{-segment:Activities.i6t}
{-segment:Figures.i6t}
{-segment:FileIO.i6t}
{-segment:MStack.i6t}
{-segment:OutOfWorld.i6t}
{-segment:Printing.i6t}
{-segment:Relations.i6t}
{-segment:RTP.i6t}
{-segment:Rulebooks.i6t}
{-segment:Sort.i6t}
{-segment:Tables.i6t}
{-segment:WorldModel.i6t}
```

§**27. Parsing Tokens.** GPRs, scope and noun filters to be used in grammar lines, but no actual grammar lines as yet.

```
{-callv:prepare_grammar}
{-call:compile_grammar_conditions}
{-log:Compiling GPR tokens for parsing various kinds of value}
{-segment:Number.i6t}
{-segment:Time.i6t}
{-call:compile_type_gprs}
{-log:Compiling noun and scope filter tokens}
{-call:compile_filters}
```

§**28. Testing commands.**

```
#IFDEF DEBUG;
{-call:write_test_text}
{-segment:Tests.i6t}
{-routine:InternalTestCases}
#ENDIF; ! DEBUG
```

§**29. I6 Inclusions.** This paragraph contains no code, by default: it's a hook on which to hang verbatim I6 material.

```
! "Include (- ... -)" inclusions with no specified position appear here.
```

§**30. Entries in constant lists.** Well: most of them, anyway. In particular, all of those which are lists of texts with substitution will be swept up, which is important for timing reasons. A second round later on will catch any later ones.

```
{-call:compile_list_constants}
```

§**31. Text Substitutions.** We now have to be quite careful about the sequence of events. Compiling the text routines is an irrevocable step, after which we must not compile any new text with substitutions. On the other hand we mustn't leave it any later, because a text substitution might contain references to the past, or involve propositions which must be deferred into routines.

```
{-log-phase:Winding up}
{-log:Compiling routines to print text containing substitutions}
{-call:compile_text_routines}
{-callv:allow_no_further_text_subs}
```

§**32. Chronology.** Similarly, this is where we wrap up all references to past tenses: after this point, we cannot safely compile any I7 condition in the past tense.

```
{-log:Compiling chronology}
{-segment:Chronology.i6t}
{-callv:allow_no_further_past_tenses}
```

§**33. Grammar.** This is the trickiest matter of timing. We had to leave the grammar lines until now because the past-tense code above might have needed to investigate whether the player's command matched a given pattern at some time in the past (a case which arose naturally in one of the example games, so which should not be dismissed as an aberration). This is therefore the earliest point at which we can know for sure that no further grammar lines are needed.

```
{-log:Compiling I6 Verb directives}
{-call:compile_grammar_verbs}
#IFTRUE ({-value:no_verb_verb_defined} == 1);
[ UnknownVerb; verb_wordnum = 0; return 'no.verb'; ];
[ PrintVerb v;
    if (v == 'no.verb') { print "do something to"; rtrue; }
    rfalse;
];
#Ifnot;
[ UnknownVerb; rfalse; ]; [ PrintVerb v; rfalse; ];
#ENDIF;
```

§**34. Deferred Propositions.** Most conditions, such as "the score is 10", and descriptions, such as "open doors which are in lighted rooms", are translated by NI into propositions in a form of predicate calculus. Sometimes these can be compiled immediately to I6 code, but other times they involve complicated searches and have to be "deferred" into special routines which will perform them. This is where we compile those routines.

```
{-log:Compiling routines from predicate calculus}
{-call:compile_deferred_propositions}
{-callv:allow_no_further_deferrals}
```

§**35. Miscellaneous Loose Ends.** And we still aren't done, because we still have:

(1) Routines which switch between possible interpretations of phrases by performing run-time type checking. (Note that these cannot involve grammar, or the past tenses, or text substitutions, or deferred propositions.)

(2) Arrays holding constant lists, such as `{2, 3, 4}`, if any.

(3) The string constants, named in the pattern `SC_*`, in alphabetical order. (This ensures that their packed addresses will have unsigned comparison ordering equivalent to alphabetical order.)

(4) "Stub" I6 constants for property names where properties aren't used, to prevent them causing errors if they are referred to in code but not actually present in any object (as can easily happen with extensions presenting optional features which the user chooses not to employ). `cap_short_name` is similarly stubbed: this doesn't correspond to any I7 property, but is used by NI to record capitalised forms of the printed name (which in turn goes into `short_name`).

(5) Counters are used to allocate cells of storage to inline phrases which need a permanent state associated with them: see the Standard Rules. Since all I7 source text has been compiled by now, we know the final values of the counters, and therefore the amount of storage we need to allocate.

(6) Similarly, each "quotation" box needs its own cell of memory.

```
{-call:compile_resolver_routines}
{-call:compile_list_constants}
{-array:ConstantListPointers}
{-call:compile_string_constants}
{-call:compile_stub_properties}
#IFNDEF cap_short_name;
Constant cap_short_name = short_name;
#ENDIF;
{-call:compile_allocated_counter_storage}
Array Runtime_Quotations_Displayed --> {-value:extent_of_runtime_quotations_array};
```

§**36. Block Values.** These are values which are pointers to more elaborate data on the memory heap, rather than values in themselves: they point to "blocks". A section of code handles the heap, and there is then one further section to support each of the kinds of value in question.

```
{-call:compile_heap_allocator}
{-segment:Flex.i6t}
{-segment:BlockValues.i6t}
{-segment:IndexedText.i6t}
{-segment:RegExp.i6t}
{-segment:StoredAction.i6t}
{-segment:Lists.i6t}
{-array:tableoffigures}
{-array:tableofsounds}
{-call:create_block_constants}
```

§**37. Signing off.** And that's all, folks.

```
! End of automatically generated I6 source
! ------------------------------------------------------------------------
```

Definitions Template B/defnt

Purpose

Miscellaneous constant definitions, usually providing symbolic names for otherwise inscrutable numbers, which are used throughout the template layer.

---

§**1. VM Target Constants.** Inform can compile story files for four different virtual machines (or VMs): Z-machine versions 5, 6 and 8, and Glulx.

When compiling to Glulx, the I6 compiler predefines the constant `TARGET_GLULX` and also sets `WORDSIZE` to 4; but when compiling to Z, we shouldn't assume it has this modern habit, so we simulate the same effect.

```
#Ifndef WORDSIZE; ! compiling with Z-code only compiler
Constant TARGET_ZCODE;
Constant WORDSIZE 2;
#Endif;
```

§**2. Wordsize-Dependent Definitions.** The old I6 library used to confuse Z-vs-G with 16-vs-32-bit, but we try to separate these distinctions here, even though at present the Z-machine is our only 16-bit target and Glulx our only 32-bit one. The `WORDSIZE` constant is the word size in bytes, so is the multiplier between `->` and `-->` offsets in I6 pointer syntax.

(1) `NULL` is used, as in C, to represent a null value or pointer. In C, this is conventionally 0, but here it is the maximum unsigned value which can be stored, pointing to the topmost byte in the directly addressable memory map; this means it is also -1 when regarded as a signed twos-complement integer, but we write it as an unsigned hexadecimal address for clarity's sake.

(2) `WORD_HIGHBIT` is the most significant bit in the VM's data word.

(3) `IMPROBABLE_VALUE` is one which is *unlikely but still possible* to be a genuine I7 value. The efficiency of some algorithms depends on how well chosen this is: they would ran badly if we chose 1, for instance.

(4) `MAX_POSITIVE_NUMBER` is the largest representable positive (signed) integer, in twos-complement form.

(5) `REPARSE_CODE` is a magic value used in the I6 library's parser to signal that some code which ought to have been parsing a command has in fact rewritten it, so that the whole command must be re-parsed afresh. (Returning this value is like throwing an exception in a language like Java, though we don't implement it that way.) A comment in the 6/11 library reads: "The parser rather gunkily adds addresses to `REPARSE_CODE` for some purposes. And expects the result to be greater than `REPARSE_CODE` (signed comparison). So Glulx Inform is limited to a single gigabyte of storage, for the moment." Guilty as charged, but the gigabyte story file is a remote prospect for now: even megabyte story files are off the horizon. Anyway, it's this comparison issue which means we need a different value for each possible word size.

```
#Iftrue (WORDSIZE == 2);
Constant NULL = $ffff;
Constant WORD_HIGHBIT = $8000;
Constant WORD_NEXTTOHIGHBIT = $4000;
```

```
Constant IMPROBABLE_VALUE = $7fe3;
Constant MAX_POSITIVE_NUMBER 32767;
Constant MIN_NEGATIVE_NUMBER -32768;
Constant REPARSE_CODE = 10000;
#Endif;
#Iftrue (WORDSIZE == 4);
Constant NULL = $ffffffff;
Constant WORD_HIGHBIT = $80000000;
Constant WORD_NEXTTOHIGHBIT = $40000000;
Constant IMPROBABLE_VALUE = $deadce11;
Constant MAX_POSITIVE_NUMBER 2147483647;
Constant MIN_NEGATIVE_NUMBER -2147483648;
Constant REPARSE_CODE = $40000000;
#Endif;
```

§**3. Z-Machine Definitions.** The Z-machine contains certain special constants and variables at fixed position in its "header"; the addresses of these are given below. See *The Z-Machine Standards Document*, version 1.0, for details.

`INDIV_PROP_START` is the lowest number of any "individual property", an I6 internal quantity defined by the compiler when the target is Glulx but not for Z.

```
#Ifdef TARGET_ZCODE;
Global max_z_object;
Constant INDIV_PROP_START 64;
! Offsets into Z-machine header:
Constant HDR_ZCODEVERSION     = $00;     ! byte
Constant HDR_TERPFLAGS        = $01;     ! byte
Constant HDR_GAMERELEASE      = $02;     ! word
Constant HDR_HIGHMEMORY       = $04;     ! word
Constant HDR_INITIALPC        = $06;     ! word
Constant HDR_DICTIONARY       = $08;     ! word
Constant HDR_OBJECTS          = $0A;     ! word
Constant HDR_GLOBALS          = $0C;     ! word
Constant HDR_STATICMEMORY     = $0E;     ! word
Constant HDR_GAMEFLAGS        = $10;     ! word
Constant HDR_GAMESERIAL       = $12;     ! six ASCII characters
Constant HDR_ABBREVIATIONS    = $18;     ! word
Constant HDR_FILELENGTH       = $1A;     ! word
Constant HDR_CHECKSUM         = $1C;     ! word
Constant HDR_TERPNUMBER       = $1E;     ! byte
Constant HDR_TERPVERSION      = $1F;     ! byte
Constant HDR_SCREENHLINES     = $20;     ! byte
Constant HDR_SCREENWCHARS     = $21;     ! byte
Constant HDR_SCREENWUNITS     = $22;     ! word
Constant HDR_SCREENHUNITS     = $24;     ! word
Constant HDR_FONTWUNITS       = $26;     ! byte
Constant HDR_FONTHUNITS       = $27;     ! byte
Constant HDR_ROUTINEOFFSET    = $28;     ! word
Constant HDR_STRINGOFFSET     = $2A;     ! word
Constant HDR_BGCOLOUR         = $2C;     ! byte
Constant HDR_FGCOLOUR         = $2D;     ! byte
```

```
Constant HDR_TERMCHARS        = $2E;     ! word
Constant HDR_PIXELSTO3        = $30;     ! word
Constant HDR_TERPSTANDARD     = $32;     ! two bytes
Constant HDR_ALPHABET         = $34;     ! word
Constant HDR_EXTENSION        = $36;     ! word
Constant HDR_UNUSED           = $38;     ! two words
Constant HDR_INFORMVERSION    = $3C;     ! four ASCII characters
#Endif;
```

§**4. Glulx Definitions.** We make similar header definitions for Glulx. Extensive further definitions, of constants needed to handle the Glk I/O layer, can be found in the "Infglk" section of "Glulx.i6t"; they are not used in the rest of the template layer, and would only get in the way here.

```
#IFDEF TARGET_GLULX;
Global unicode_gestalt_ok; ! Set if interpreter supports Unicode
! Offsets into Glulx header and start of ROM:
Constant HDR_MAGICNUMBER      = $00;     ! long word
Constant HDR_GLULXVERSION     = $04;     ! long word
Constant HDR_RAMSTART         = $08;     ! long word
Constant HDR_EXTSTART         = $0C;     ! long word
Constant HDR_ENDMEM           = $10;     ! long word
Constant HDR_STACKSIZE        = $14;     ! long word
Constant HDR_STARTFUNC        = $18;     ! long word
Constant HDR_DECODINGTBL      = $1C;     ! long word
Constant HDR_CHECKSUM         = $20;     ! long word
Constant ROM_INFO             = $24;     ! four ASCII characters
Constant ROM_MEMORYLAYOUT     = $28;     ! long word
Constant ROM_INFORMVERSION    = $2C;     ! four ASCII characters
Constant ROM_COMPVERSION      = $30;     ! four ASCII characters
Constant ROM_GAMERELEASE      = $34;     ! short word
Constant ROM_GAMESERIAL       = $36;     ! six ASCII characters
#Endif;
```

§**5. Powers of Two.** I6 lacks support for logical shifts, and the Z-machine opcodes which bear on this are not always well supported, so the I6 library has traditionally used a lookup table for the values of 2^{15-n} where $0 \le n \le 11$.

```
Array PowersOfTwo_TB
--> $$100000000000
    $$010000000000
    $$001000000000
    $$000100000000
    $$000010000000
    $$000001000000
    $$000000100000
    $$000000010000
    $$000000001000
    $$000000000100
    $$000000000010
    $$000000000001;
Array IncreasingPowersOfTwo_TB
```

```

    $$0010000000000000
    $$0100000000000000
    $$1000000000000000;
```

§**6. Text Styles.** These are the styles of text distinguished by the template layer, though they are not required to look different from each other on any given VM. The codes are independent of the VM targetted, though in fact they are equal to Glulx style numbers as conventionally used. (The Z-machine renders some as roman, some as bold, but for instance makes `HEADER_VMSTY` and `SUBHEADER_VMSTY` indistinguishable to the eye.) Glulx's system of styles is one of its weakest points from an IF author's perspective, since it is all but impossible to achieve the text effects one might want – boldface, for instance, or red text – and text rendering is almost the only area in which it is clearly inferior to the Z-machine, which it was designed to replace. Still, using these styles when we can will get the most out of it, and for unornamental works Glulx is fine in practice.

```
Constant NORMAL_VMSTY     = 0;
Constant HEADER_VMSTY     = 3;
Constant SUBHEADER_VMSTY  = 4;
Constant ALERT_VMSTY      = 5;
Constant NOTE_VMSTY       = 6;
Constant BLOCKQUOTE_VMSTY = 7;
Constant INPUT_VMSTY      = 8;
```

§**7. Colour Numbers.** These are traditional colour names: quite who it was who thought that azure was the same colour as cyan is now unclear. Colour is, again, not easy to arrange on Glulx, but there is some workaround code.

```
Constant CLR_DEFAULT = 1;
Constant CLR_BLACK   = 2;
Constant CLR_RED     = 3;
Constant CLR_GREEN   = 4;
Constant CLR_YELLOW  = 5;
Constant CLR_BLUE    = 6;
Constant CLR_MAGENTA = 7; Constant CLR_PURPLE  = 7;
Constant CLR_CYAN    = 8; Constant CLR_AZURE   = 8;
Constant CLR_WHITE   = 9;
```

§**8. Window Numbers.** Although Glulx can support elaborate tessalations of windows on screen (if the complexity of handling this can be mastered), the Z-machine has much more limited resources in general, so the template layer assumes a simple screen model: there are just two screen areas, the scrolling main window in which commands are typed and responses printed, and the fixed status line bar at the top of the screen.

```
Constant WIN_ALL     = 0; ! Both windows at once
Constant WIN_STATUS  = 1;
Constant WIN_MAIN    = 2;
```

§**9. Paragraphing Flags.** I am not sure many dictionaries would countenance "to paragraph" as a verb, but never mind: the reference here is to the algorithm used to place paragraph breaks within text, which uses bitmaps composed of the following.

```
Constant PARA_COMPLETED          = 1;
Constant PARA_PROMPTSKIP         = 2;
Constant PARA_SUPPRESSPROMPTSKIP = 4;
Constant PARA_NORULEBOOKBREAKS   = 8;
Constant PARA_CONTENTEXPECTED    = 16;
```

§**10. Descriptors in the Language of Play.** The following constants, which must be different in value from the number of any I6 attribute, are used in the `LanguageDescriptors` table found in the definition of the language of play.

```
Constant POSSESS_PK  = $100;
Constant DEFART_PK   = $101;
Constant INDEFART_PK = $102;
```

§**11. Run-Time Problem Numbers.** The enumeration sequence here must correspond to that in the file of RTP texts, which is used to generate the HTML pages displayed by the Inform user interface when a run-time problem has occurred. (For instance, the file of RTP texts includes the heading "P17 - Can't divide by zero", equivalent to `RTP_DIVZERO` being 17 below.) There is no significance to the sequence, which is simply the historical order in which they were added to I7.

```
Constant RTP_BACKDROP               = 1;
Constant RTP_EXITDOOR               = 2;
Constant RTP_NOEXIT                 = 3;
Constant RTP_CANTCHANGE             = 4;
Constant RTP_IMPREL                 = 5;
Constant RTP_RULESTACK              = 6;
Constant RTP_TOOMANYRULEBOOKS       = 7;
Constant RTP_TOOMANYEVENTS          = 8;

Constant RTP_TABLE_CANTSAVE          = 34;
Constant RTP_TABLE_WONTFIT           = 35;
Constant RTP_TABLE_BADFILE           = 36;
Constant RTP_LOWLEVELERROR           = 37;
Constant RTP_DONTIGNORETURNSEQUENCE  = 38;
Constant RTP_SAYINVALIDSNIPPET       = 39;
Constant RTP_SPLICEINVALIDSNIPPET    = 40;
Constant RTP_INCLUDEINVALIDSNIPPET   = 41;
Constant RTP_LISTWRITERMEMORY        = 42;
Constant RTP_CANTREMOVEPLAYER        = 43;
Constant RTP_CANTREMOVEDOORS         = 44;
Constant RTP_CANTCHANGEOFFSTAGE      = 45;
Constant RTP_MSTACKMEMORY            = 46;
Constant RTP_TYPECHECK               = 47;
Constant RTP_FILEIOERROR             = 48;
Constant RTP_HEAPERROR               = 49;
Constant RTP_LISTRANGEERROR          = 50;
Constant RTP_REGEXPSYNTAXERROR       = 51;
Constant RTP_NOGLULXUNICODE          = 52;
Constant RTP_BACKDROPONLY            = 53;
Constant RTP_NOTTHING                = 54;
Constant RTP_SCENEHASNTSTARTED       = 55;
Constant RTP_SCENEHASNTENDED         = 56;
Constant RTP_NEGATIVEROOT            = 57;
```

§**12. Relation Types.** These names are identical to symbolic names used in the NI source code, and are used to show whether a relation is one to one, various to one, and so forth. `Sym` means that it is forcibly symmetric, `Equiv` that it is an equivalence relation ("in groups"). An implicitly-defined relation is one which can't be used for practical purposes. A relation by routine is one for which $R(x, y)$ is true if and only if a given routine, called with arguments x and y, says so: it is therefore read only.

```
Constant Relation_Implicit   = -1;
Constant Relation_OtoO       = 1;
Constant Relation_OtoV       = 2;
Constant Relation_VtoO       = 3;
Constant Relation_VtoV       = 4;
Constant Relation_Sym_OtoO   = 5;
Constant Relation_Sym_VtoV   = 6;
Constant Relation_Equiv      = 7;
Constant Relation_ByRoutine  = 8;
```

§**13. Template Activities.** These are the activities defined in the Standard Rules. Most, though not all, are carried out by explicit function calls in the template layer, which is why we need their ID numbers: note that NI assigns each activity a unique ID number on creation, counting upwards from 0, and that it processes the Standard Rules before any other source text. (These numbers must correspond *both* to those in the source of NI, *and* to the creation sequence in the Standard Rules.)

```
Constant PRINTING_THE_NAME_ACT           = 0;
Constant PRINTING_THE_PLURAL_NAME_ACT    = 1;
Constant PRINTING_A_NUMBER_OF_ACT        = 2;
Constant PRINTING_ROOM_DESC_DETAILS_ACT  = 3;
Constant LISTING_CONTENTS_ACT            = 4;
Constant GROUPING_TOGETHER_ACT           = 5;
Constant WRITING_A_PARAGRAPH_ABOUT_ACT   = 6;
Constant LISTING_NONDESCRIPT_ITEMS_ACT   = 7;

Constant PRINTING_NAME_OF_DARK_ROOM_ACT  = 8;
Constant PRINTING_DESC_OF_DARK_ROOM_ACT  = 9;
Constant PRINTING_NEWS_OF_DARKNESS_ACT   = 10;
Constant PRINTING_NEWS_OF_LIGHT_ACT      = 11;
Constant REFUSAL_TO_ACT_IN_DARK_ACT      = 12;

Constant CONSTRUCTING_STATUS_LINE_ACT    = 13;
Constant PRINTING_BANNER_TEXT_ACT        = 14;

Constant READING_A_COMMAND_ACT           = 15;
Constant DECIDING_SCOPE_ACT              = 16;
Constant DECIDING_CONCEALED_POSSESS_ACT  = 17;
Constant DECIDING_WHETHER_ALL_INC_ACT    = 18;
Constant CLARIFYING_PARSERS_CHOICE_ACT   = 19;
Constant ASKING_WHICH_DO_YOU_MEAN_ACT    = 20;
Constant PRINTING_A_PARSER_ERROR_ACT     = 21;
Constant SUPPLYING_A_MISSING_NOUN_ACT    = 22;
Constant SUPPLYING_A_MISSING_SECOND_ACT  = 23;
Constant IMPLICITLY_TAKING_ACT           = 24;
Constant STARTING_VIRTUAL_MACHINE_ACT    = 25;

Constant AMUSING_A_VICTORIOUS_PLAYER_ACT = 26;
Constant PRINTING_PLAYERS_OBITUARY_ACT   = 27;
Constant DEALING_WITH_FINAL_QUESTION_ACT = 28;

Constant PRINTING_LOCALE_DESCRIPTION_ACT = 29;
```

```
Constant CHOOSING_NOTABLE_LOCALE_OBJ_ACT = 30;
Constant PRINTING_LOCALE_PARAGRAPH_ACT   = 31;
```

§**14. Template Rulebooks.** Rulebooks are created in a similar way, and again are numbered upwards from 0 in order of creation. These are the ones used in the template layer. (These numbers must correspond *both* to those in the source of NI, *and* to the creation sequence in the Standard Rules.)

```
Constant PROCEDURAL_RB                  = 0;
Constant STARTUP_RB                     = 1;
Constant TURN_SEQUENCE_RB               = 2;
Constant SHUTDOWN_RB                    = 3;
Constant WHEN_PLAY_BEGINS_RB            = 5;
Constant WHEN_PLAY_ENDS_RB              = 6;
Constant ACTION_PROCESSING_RB           = 8;
Constant SETTING_ACTION_VARIABLES_RB    = 9;
Constant SPECIFIC_ACTION_PROCESSING_RB  = 10;
Constant ACCESSIBILITY_RB               = 12;
Constant REACHING_INSIDE_RB             = 13;
Constant REACHING_OUTSIDE_RB            = 14;
Constant VISIBLE_RB                     = 15;
Constant PERSUADE_RB                    = 16;
Constant UNSUCCESSFUL_ATTEMPT_RB        = 17;
Constant AFTER_RB                       = 22;
Constant REPORT_RB                      = 23;
```

§**15. Data Type IDs.** These are filled in automatically by NI, and have the same names as are used in the NI source (and in the Types.i6t section): for instance `NUMBER_TY`.

```
{-call:compile_I6_constants_for_typenames}
```

§**16. Parser Error Numbers.** The traditional ways in which the I6 library's parser, which we adopt here more or less intact, can give up on a player's command. See the *Inform Designer's Manual*, 4th edition, for details.

```
Constant STUCK_PE     = 1;
Constant UPTO_PE      = 2;
Constant NUMBER_PE    = 3;
Constant ANIMA_PE     = 4;
Constant CANTSEE_PE   = 5;
Constant TOOLIT_PE    = 6;
Constant NOTHELD_PE   = 7;
Constant MULTI_PE     = 8;
Constant MMULTI_PE    = 9;
Constant VAGUE_PE     = 10;
Constant EXCEPT_PE    = 11;
Constant VERB_PE      = 12;
Constant SCENERY_PE   = 13;
Constant ITGONE_PE    = 14;
Constant JUNKAFTER_PE = 15;
Constant TOOFEW_PE    = 16;
```

```
Constant NOTHING_PE   = 17;
Constant ASKSCOPE_PE  = 18;
Constant NOTINCONTEXT_PE = 19;
Constant BLANKLINE_PE = 20; ! Not formally a parser error, but used by I7 as if
```

§**17. Scope Searching Reasons.** The parser makes use of a mechanism for searching through the objects currently "in scope", which basically means visible to the actor who would perform the action envisaged by the command being parsed. It is sometimes useful to behave differently depending on why this scope searching is being done, so the following constants enumerate the possibilities.

I6's `EACH_TURN_REASON`, `REACT_BEFORE_REASON` and `REACT_AFTER_REASON` have been removed from this list as no longer meaningful; hence the lacuna in numbering.

```
Constant PARSING_REASON       = 0;
Constant TALKING_REASON       = 1;
Constant EACH_TURN_REASON     = 2;
Constant LOOPOVERSCOPE_REASON = 5;
Constant TESTSCOPE_REASON     = 6;
```

§**18. Token Types.** Tokens are the indecomposable pieces of a grammar line making up a possible reading of a command; some are literal words, others stand for "any named object in scope", and so on. The following codes identify the possibilities. The `*_TOKEN` constants must not be altered without modifying the I6 compiler to match (so, basically, they must not be altered at all).

```
Constant ILLEGAL_TT         = 0;    ! Types of grammar token: illegal
Constant ELEMENTARY_TT      = 1;    !     (one of those below)
Constant PREPOSITION_TT     = 2;    !     e.g. 'into'
Constant ROUTINE_FILTER_TT  = 3;    !     e.g. noun=CagedCreature
Constant ATTR_FILTER_TT     = 4;    !     e.g. edible
Constant SCOPE_TT           = 5;    !     e.g. scope=Spells
Constant GPR_TT             = 6;    !     a general parsing routine

Constant NOUN_TOKEN         = 0;    ! The elementary grammar tokens, and
Constant HELD_TOKEN         = 1;    ! the numbers compiled by I6 to
Constant MULTI_TOKEN        = 2;    ! encode them
Constant MULTIHELD_TOKEN    = 3;
Constant MULTIEXCEPT_TOKEN  = 4;
Constant MULTIINSIDE_TOKEN  = 5;
Constant CREATURE_TOKEN     = 6;
Constant SPECIAL_TOKEN      = 7;
Constant NUMBER_TOKEN       = 8;
Constant TOPIC_TOKEN        = 9;
Constant ENDIT_TOKEN        = 15;   ! Value used to mean "end of grammar line"
```

§**19. GPR Return Values.** GRP stands for "General Parsing Routine", an I6 routine which acts as a grammar token: again, see the *Inform Designer's Manual*, 4th edition, for details.

In Library 6/11, `GPR_NOUN` is defined as `$ff00`, but this would fail on Glulx: it needs to be `$ffffff00` on 32-bit virtual machines. It appears that `GPR_NOUN` to `GPR_CREATURE`, though documented in the old *Inform Translator's Manual*, were omitted when this was consolidated into the DM4, so that they effectively disappeared from view. But they might still be useful for implementing inflected forms of nouns, so we have retained them here regardless.

```
Constant GPR_FAIL           = -1;   ! Return values from General Parsing
Constant GPR_PREPOSITION    = 0;    ! Routines
Constant GPR_NUMBER         = 1;
Constant GPR_MULTIPLE       = 2;
Constant GPR_REPARSE        = REPARSE_CODE;
Constant GPR_NOUN           = -256; ! Reparse, but as |NOUN_TOKEN| this time
Constant GPR_HELD           = GPR_NOUN + 1; ! And so on
Constant GPR_MULTI          = GPR_NOUN + 2;
Constant GPR_MULTIHELD      = GPR_NOUN + 3;
Constant GPR_MULTIEXCEPT    = GPR_NOUN + 4;
Constant GPR_MULTIINSIDE    = GPR_NOUN + 5;
Constant GPR_CREATURE       = GPR_NOUN + 6;
```

§**20. List Styles.** These constants make up bitmaps of the options in use when listing objects.

```
Constant NEWLINE_BIT        = $$0000000000000001; ! New-line after each entry
Constant INDENT_BIT         = $$0000000000000010; ! Indent each entry by depth
Constant FULLINV_BIT        = $$0000000000000100; ! Full inventory information after entry
Constant ENGLISH_BIT        = $$0000000000001000; ! English sentence style, with commas and and
Constant RECURSE_BIT        = $$0000000000010000; ! Recurse downwards with usual rules
Constant ALWAYS_BIT         = $$0000000000100000; ! Always recurse downwards
Constant TERSE_BIT          = $$0000000001000000; ! More terse English style
Constant PARTINV_BIT        = $$0000000010000000; ! Only brief inventory information after entry
Constant DEFART_BIT         = $$0000000100000000; ! Use the definite article in list
Constant WORKFLAG_BIT       = $$0000001000000000; ! At top level (only), only list objects
                                                  ! which have the "workflag" attribute
Constant ISARE_BIT          = $$0000010000000000; ! Print " is" or " are" before list
Constant CONCEAL_BIT        = $$0000100000000000; ! Omit objects with "concealed" or "scenery":
                                                  ! if WORKFLAG_BIT also set, then does not
                                                  ! apply at top level, but does lower down
Constant NOARTICLE_BIT      = $$0001000000000000; ! Print no articles, definite or not
Constant EXTRAINDENT_BIT    = $$0010000000000000; ! New in I7: extra indentation of 1 level
Constant CFIRSTART_BIT      = $$0100000000000000; ! Capitalise first article in list
```

§**21. Lengths Of Time.** Inform measures time in minutes.

```
Constant QUARTER_HOUR = 15;
Constant HALF_HOUR = 30;
Constant ONE_HOUR = 60;
Constant TWELVE_HOURS = 720;
Constant TWENTY_FOUR_HOURS = 1440;
```

§**22. Empty Text.** The I6 compiler does not optimise string compilation: if it needs to compile the (packed, read-only) string `"exemplum"` twice, it will compile two copies. This is slightly wasteful on memory, though in practice the loss is not enough for us to care. But we do want to avoid this in I7 because, to make string-sorting algorithms more efficient, we want direct numerical comparison of packed addresses to be equivalent to string comparison: and that means the text "exemplum" has to be compiled once and once only. There's a general mechanism for this in NI, but the single case most often needed is the empty text, since this is the default value for text variables and properties: we give it a name as follows.

(This works because I6 constant definition is not like C preprocessor macro expansion: `EMPTY_TEXT_VALUE` is equated with the address resulting from compiling `""`, rather than being replaced with the blank text to be recompiled each time.)

```
Constant EMPTY_TEXT_VALUE "";
```

§**23. Empty Table.** Similarly: the default value for the "table" kind of value, a Table containing no rows and no columns.

```
Array TheEmptyTable --> 0 0;
```

§**24. Empty Rulebook.** Similarly. An empty rulebook is one whose array has first word equal to `NULL`: we define a sequence of four `$ff` bytes so that the first word will be `NULL` on either 16-bit or 32-bit VMs. As with the empty text, this array is the value of many empty rulebooks: rulebook arrays are read-only, so there is no risk of a clash.

```
Array EMPTY_RULEBOOK -> $ff $ff $ff $ff;
```

§**25. Empty Set.** The falsity proposition describes the empty set of objects, and is the zero value for the "description" kind of value.

```
[ Prop_Falsity reason obj; return 0; ];
```

§**26. Score and Rankings Table.** The following command tells NI to compile constant definitions for `MAX_SCORE` and/or `RANKING_TABLE`, in cases where there are scores and rankings. If there's no score, we define `MAX_SCORE` as 0 anyway; if there's no ranking table, `RANKING_TABLE` is left undefined, so that we can `#ifdef` this possibility later.

```
{-call:compile_max_score}
Default MAX_SCORE 0;
```

§**27. Template Attributes.** An I6 attribute is equivalent to an I7 "either/or property", though the latter are not always translated into I6 attributes because the Z-machine has only a limited number of attributes to use. Here, we define attributes used by the template.

Many concepts in I6 correspond directly to their successors in I7, even if details may vary. (Value properties are a case in point.) Attributes are the opposite of this: indeed, no I6 concept is more fragmented in its I7 equivalents. All but one of the old I6 library attributes are still used (the `general` attribute, for miscellaneous use, has been removed: it more often invited abuse than use); and a few new attributes have been added. But they are used for a variety of purposes. Some do correspond exactly to either/or properties in I7, but others are a sort of signature for I7 kinds. (So that for I7 use they are read-only.) Others still are used by the template layer as part of the implementation of services for I7, but are not visible to I7 source text as storage.

```
Attribute absent; ! Used to mark objects removed from play
Attribute animate; ! I6-level marker for I7 kind "person"
Attribute clothing; ! = I7 "wearable"
Attribute concealed; ! = I7 "undescribed"
Attribute container; ! I6-level marker for I7 kind "container"
Attribute door; ! I6-level marker for I7 kind "door"
Attribute edible; ! = I7 "edible" vs "inedible"
Attribute enterable; ! = I7 "enterable"
Attribute light; ! = I7 "lighted" vs "dark"
Attribute lockable; ! = I7 "lockable"
Attribute locked; ! = I7 "locked"
Attribute moved; ! = I7 "handled"
Attribute on; ! = I7 "switched on" vs "switched off"
Attribute open; ! = I7 "open" vs "closed"
Attribute openable; ! = I7 "openable"
Attribute scenery; ! = I7 "scenery"
Attribute static; ! = I7 "fixed in place" vs "portable"
Attribute supporter; ! I6-level marker for I7 kind "supporter"
Attribute switchable; ! I6-level marker for I7 kind "device"
Attribute talkable; ! Not currently used by I7, but retained for possible future use
Attribute transparent; ! = I7 "transparent" vs "opaque"
Attribute visited; ! = I7 "visited"
Attribute worn; ! marks that an object tree edge represents wearing

Attribute male; ! not directly used by I7, but available for languages with genders
Attribute female; ! = I7 "female" vs "male"
Attribute neuter; ! = I7 "neuter"
Attribute pluralname; ! = I7 "plural-named"
Attribute proper; ! = I7 "proper-named"
Attribute remove_proper; ! remember to remove proper again when using ChangePlayer next

Attribute initially_carried; ! New in I7
Constant privately_named = initially_carried; ! = I7 "privately-named"; not used at run-time
Attribute mentioned; ! New in I7
Attribute pushable; ! New in I7

Attribute mark_as_room; ! Used in I7 to speed up testing "ofclass K1_room"
Attribute mark_as_thing; ! Used in I7 to speed up testing "ofclass K2_thing"

Attribute workflag; ! = I7 "marked for listing", but basically temporary workspace
Attribute workflag2; ! new in I7 and also temporary workspace
Constant list_filter_permits = initially_carried; ! another I7 listwriter convenience
```

§**28. Template Properties.** As remarked above, these more often correspond to value properties in I7. To an experienced I6 user, though, the death toll of abolished I6 properties in I7 is breathtaking: in alphabetical order, `after`, `cant_go`, `daemon`, `each_turn`, `invent`, `life`, `number`, `orders`, `react_after`, `react_before`, `time_left`, `time_out`, `when_closed`, `when_off`, `when_on`, `when_open`. In May 2008, the direction properties `n_to`, `s_to`, `e_to`, ..., `out_to` joined the list of the missing.

The losses are numerous because of the shift from I6's object orientation to I7's rule orientation: information about the behaviour of objects is no longer thought of as data attached to them. At that, it could have been worse: a few unused I6 library properties have been retained for possible future use.

```
Property add_to_scope; ! used as in I6 to place component parts in scope
Property article "a"; ! used as in I6 to implement articles
Property capacity 100; ! = I7 "carrying capacity"
Property component_child; ! new in I7: forest structure holding "part of" relation
Property component_parent; ! new in I7
Property component_sibling; ! new in I7
Property description; ! = I7 "description"
Property door_dir; ! used to implement two-sided doors, but holds direction object, not a property
Property door_to; ! used as in I6 to implement two-sided doors
Property found_in; ! used as in I6 to implement two-sided doors and backdrops
Property initial; ! = I7 "initial description"
Property list_together; ! used as in I6 to implement "grouping together" activity
Property map_region; ! new in I7
Property parse_name 0; ! used as in I6 to implement "Understand... as..." grammars
Property plural; ! used as in I6 to implement plural names for duplicate objects
Property regional_found_in; ! new in I7
Property room_index; ! new in I7: storage for route-finding
Property short_name 0; ! = I7 "printed name"
Property vector; ! new in I7: storage for route-finding
Property with_key; ! = I7 "matching key"

Property IK_0; ! Instance count of the kind of the current object
Property IK_1; ! These are instance counts within kinds K1, K2, ...
Property IK_2; ! and it is efficient to declare the common ones with Property
Property IK_4; ! since this results in a slightly smaller story file
Property IK_5;
Property IK_6;
Property IK_8;

Property IK1_link; ! These are for linked lists used to make searches faster
Property IK2_link; ! and again it's memory-efficient to declare the common ones
Property IK5_link; !
Property IK6_link; !
Property IK8_link; !

Property articles; ! not used by I7, but an interesting hook in the parser
Property grammar; ! not used by I7, but an interesting hook in the parser
Property inside_description; ! not used by I7, but an interesting hook in the locale code
Property short_name_indef 0; ! not used by I7, but an interesting hook in the listmaker
```

§**29. Loss of Life.** The loss of `life` is so appalling that I6 will not even compile a story file which doesn't define the property number `life` (well, strictly speaking, it checks the presence of constants suggesting the I6 library first, but the template layer does define constants like that). We define it as a null constant to be sure of avoiding any valid property number; I6 being typeless, that enables the veneer to compile again. (The relevant code is in `CA__Pr`, defined in the `veneer.c` section of I6.)

```
Constant life = NULL;
```

§**30. Action Count.** The number of valid I7 actions in existence.

```
Constant ActionCount = {-value:NUMBER_CREATED(action_name)};
```

§**31. Fake Actions.** Though sometimes useful for I6 coding tricks, fake actions – action numbers not corresponding to any action, but different from those of valid actions, and useable with a number of action syntaxes – are not conceptually present in I7 source text. They can only really exist at the I6 level because I6 is typeless; in I7 terms, there is no convenient kind of value which could represent both actions and fake actions while protecting each from confusion with the other.

See the *Inform Designer's Manual*, 4th edition, for what these are used for.

The following fake actions from the I6 library have been dropped here: `##LetGo`, `##Receive`, `##ThrownAt`, `##Prompt`, `##Places`, `##Objects`, `##Order`, `##NotUnderstood`.

```
Fake_Action ListMiscellany;
Fake_Action Miscellany;
Fake_Action PluralFound;
Fake_Action TheSame;
```

OrderOfPlay Template B/ordt

Purpose

The sequence of events in play: the Main routine which runs the startup rulebook, the turn sequence rulebook and the shutdown rulebook; and most of the I6 definitions of primitive rules in those rulebooks.

---

§**1. Main.** This is where every I6 story file begins execution: it can end either by returning, or by a `quit` statement or equivalent opcode. (In I7 this does indeed happen when the quitting the game action is carried out, or when QUIT is typed as a reply to the final question; it's only if the user has altered the shutdown rulebook that we might ever actually return from `Main`.) The return value from `Main` is not meaningful.

The `EarlyInTurnSequence` flag is used to enforce the requirement that the "parse command rule" and "generate action rule" do nothing unless the turn sequence rulebook is being followed directly from `Main`, an anomaly explained in the Standard Rules.

```
Global EarlyInTurnSequence;
[ Main;
    #ifdef TARGET_ZCODE; max_z_object = #largest_object - 255; #endif;
    ProcessRulebook(STARTUP_RB);
    #ifdef DEBUG; InternalTestCases(); #endif;
    while (true) {
        while (deadflag == false) {
            EarlyInTurnSequence = true;
            FollowRulebook(TURN_SEQUENCE_RB);
        }
        if (FollowRulebook(SHUTDOWN_RB) == false) return;
    }
];
```

§**2. Virtual Machine Startup Rule.** Note that we consider the three rulebooks for the "starting the virtual machine" activity, but do not formally carry it out, because that might invoke procedural rules: this early in the run, before the screen can accept text, for instance, procedural rules would be risky. We then delegate to the appropriate VM-specific section of code for the real work. The printing of three blank lines at the start of play is traditional: on early Z-machine interpreters such as InfoTaskForce and Zip it was a necessity because of the way they buffered output. On modern windowed ones it still helps to space the opening text better.

```
[ VIRTUAL_MACHINE_STARTUP_R;
    ProcessRulebook(Activity_before_rulebooks-->STARTING_VIRTUAL_MACHINE_ACT);
    ProcessRulebook(Activity_for_rulebooks-->STARTING_VIRTUAL_MACHINE_ACT);
    ProcessRulebook(Activity_after_rulebooks-->STARTING_VIRTUAL_MACHINE_ACT);
    VM_Initialise();
    print "^^^";
    rfalse;
];
```

§**3. Initial Situation.** The array `InitialSituation` is compiled by NI and contains:

(0) The object number for the player, which is usually `selfobj`.
(1) The object in or on which the player begins, if he does. (This will always be an enterable container or supporter, or `nothing`.)
(2) The room in which the player begins, which is usually the first room created in the source text.
(3) The initial time of day, which is usually 9 AM.

The start object and start room are meaningful only if the player's object is compiled outside of the object tree (as can happen if the source text reads, say, "Mrs Bridges is a woman. The player is Mrs Bridges."): in other circumstances they are often correct, but this must not be relied on.

```
Constant PLAYER_OBJECT_INIS = 0;
Constant START_OBJECT_INIS = 1;
Constant START_ROOM_INIS = 2;
Constant START_TIME_INIS = 3;
{-array:InitialSituation}
```

§**4. Initialise Memory Rule.** This rule amalgamates some minimal initialisations which all need to happen before we can risk using some of the more exotic I7 data types:

(a) The language definition might call for initialisation, although the default language of play (English) does not.
(b) A handful of variables are filled in. `I7_LOOKMODE` is a constant created by the use options "use full-length room descriptions" or "use abbreviated room descriptions", but otherwise not existing. It is particularly important that `player` have the correct value, as the process of initialising the memory heap uses the player as the presumed actor when creating memory representations of literal stored actions where no actor was specified; this is why `player` is initialised here and not in the "position player in model world rule" below. The other interesting point here is that we explicitly set `location` and `real_location` to `nothing`, which is certainly incorrect, even though we know better. We do this so that the "update chronological records rule" cannot see where the player is: see the Standard Rules for an explanation of why this is, albeit perhaps dubiously, a good thing.
(c) We start the machinery needed to check that property accesses are valid during play.
(d) And we initialise the memory allocation heap, and expand the literal constants, as hinted above: these are called "block constants" since they occupy blocks of memory.

The `not_yet_in_play` flag, which is cleared when the first command is about to be read from the keyboard, suppresses the standard status line text: thus, if there is some long text to read before the player finds out where he is, the surprise will not be spoiled.

```
[ INITIALISE_MEMORY_R;
    #Ifdef LanguageInitialise; LanguageInitialise(); #Endif;
    not_yet_in_play = true;
    #ifdef I7_LOOKMODE; lookmode = I7_LOOKMODE; #endif;
    player = InitialSituation-->PLAYER_OBJECT_INIS;
    the_time = InitialSituation-->START_TIME_INIS;
    real_location = nothing;
    location = nothing;
    CreatePropertyOffsets();
    HeapInitialise(); ! Create a completely unused memory allocation heap
    InitialHeapAllocation(); ! Allocate empty blocks for variables, properties, and such
    CreateBlockConstants(); ! Allocate and fill in blocks for constant values
    DistributeBlockConstants(); ! Ensure these exist in multiple independent copies when needed
    rfalse;
];
```

§**5. Seed Random Number Generator Rule.** Unless a seed is provided by NI, and it won't be for released story files, the VM's interpreter is supposed to start up with a good seed in its random number generator: something usually derived from, say, the milliseconds part of the current time of day, which is unlikely to repeat or show any pattern in real-world use. However, early Z-machine interpreters often did this quite badly, starting with poor seed values which meant that the first few random numbers always had something in common (being fairly small in their range, for instance). To obviate this we extract and throw away 100 random numbers to get the generator going, shaking out more obvious early patterns, but that cannot really help much if the VM interpreter's RNG is badly written. "Anyone who considers arithmetical methods of producing random digits is, of course, in a state of sin" (von Neumann).

```
[ SEED_RANDOM_NUMBER_GENERATOR_R i;
    if ({-value:rng_seed_at_start_of_play}) VM_Seed_RNG({-value:rng_seed_at_start_of_play});
    for (i=1: i<=100: i++) random(i);
    rfalse;
];
```

§**6. Position Player In Model World Rule.** This seems as good a place as any to write down the invariant we attempt to maintain for the player's position variables:

(1) The `player` variable is the object through which the player plays, which is always a person: its value is always set by starting from `selfobj` and then making a sequence of 0 or more `ChangePlayer(new_value)` calls. (This enables us to make sure it has the correct property values for printed name and so forth.)

(2) The `location` is always either the current room, a valid I7 room, or `thedark`, which is not a valid I7 object but is distinguishable both from all I7 objects and from `nothing`. The `real_location` is always the current room, which is always a valid I7 room. `location` equals `thedark` if and only if the player does not have light to see by; the routine `SilentlyConsiderLight` updates this without printing any messages to announce the fall or lifting of darkness (hence "silently").

(3) The `player` object is always in the subtree of `real_location`, and is always in a chain $O_1 < O_2 < ... < O_n$ where O_1 is the player, O_n is `real_location`, $n \geq 2$ and $O_2, ..., O_{n-1}$ are all either enterable containers, enterable supporters, or component parts of such. The routine `LocationOf`, applied to the player object, always agrees with `real_location`.

(4) "Floating" objects, such as backdrops and two-sided doors, are in theory present in more than one room at once. In practice they can only be in a single position in the I6 object tree at any one time. The rule is that if they are theoretically present in the `real_location`, then they are actually present in the subtree of `real_location`. The routine `MoveFloatingObjects` updates this, and must be called whenever the player moves from one room to another.

(5) Any objects carried by the player have the I6 `moved` attribute set. The `SACK_OBJECT` variable is always set to the object of kind "player's holdall" which the player has most recently been carrying, or had as a component part of himself. The "note object acquisitions" rule updates this.

These invariants are usually all false before the following rule is executed; they are all true once it has completed. In addition, because the global action variables usually hold details of the action most recently carried out, we initialise these as if the most recent action had been the player waiting. (Nobody ought to use these variables at this point, but in case they do use them by accident in a "when play begins" rule, we want Inform to behave predictably and without type-unsafe values entering code.)

```
[ POSITION_PLAYER_IN_MODEL_R player_to_be;
    player = selfobj;
    player_to_be = InitialSituation-->PLAYER_OBJECT_INIS;
    location = LocationOf(player_to_be);
    if (location == 0) {
        location = InitialSituation-->START_ROOM_INIS;
        if (InitialSituation-->START_OBJECT_INIS)
```

```
            move player_to_be to InitialSituation-->START_OBJECT_INIS;
        else move player_to_be to location;
    }
    if (player_to_be ~= player) { remove selfobj; ChangePlayer(player_to_be); }
    real_location = location; SilentlyConsiderLight();
    NOTE_OBJECT_ACQUISITIONS_R(); MoveFloatingObjects();
    actor = player; act_requester = nothing; actors_location = real_location; action = ##Wait;
    rfalse;
];
```

§**7. Parse Command Rule.** This section contains only two primitive rules from the turn sequence rulebook, the matched pair of the "parse command rule" and the "generate action rule"; the others are found in the sections on Light and Time.

We use almost identically the same parser as that in the I6 library, since it is a well-proven and understood algorithm. The I6 parser returns some of its results in a supplied array (here `parser_results`, though the I6 library used to call this `inputobjs`), but others are in global variables:

(1) The `parser_results` array holds four words, used as indexed by the constants below.
   (a) The action can be a valid I6 action number, or an I6 "fake action", a concept not used overtly in I7. Most valid I6 actions correspond exactly to I7 actions, but in principle it is possible to define (say) extra debugging commands entirely at the I6 level.
   (b) The count `NO_INPS_PRES` is always 0, 1 or 2, and then that many of the next two words are meaningful.
   (c) Each of the "inp" values is either 0, meaning "put the multiple object list here"; or 1, meaning "not an object but a value"; or a valid I6 object. (We use the scoping rules to ensure that any I6 object visible to the parser is also a valid I7 object, so – unlike with actions – we need not distinguish between the two.)

(2) The global variable `actor` is set to the person asked to carry out the command, or is the same as `player` if nobody was mentioned. Thus it will be the object for Floyd in the command FLOYD, GET PERMIT, but will be just `player` in the command EAST.

(3) The global variables `special_number1` and, if necessary, `special_number2` hold values corresponding to the first and second of the "inps" to be returned as 1. Thus, if one of the "inps" is a value and the other is an object, then `special_number1` is that value; only if both are values rather than objects will `special_number2` be used. There is no indication of the data type of these values: I6 is typeless.

(4) At most one of the "inps" is permitted to be 1, referring to a multiple object list. (And a multiple value list is forbidden.) If this happens, the list of objects is stored in an I6 table array (i.e., with the 0th word being the number of subsequent words) called `multiple_object`, and the parser will have set the `toomany_flag` if an overflow occurred – that is, if the list was truncated because it originally called for more than 63 objects.

(5) The global variable `meta` is set if the action is one marked as such in the I6 grammar. A confusion in the design of I6 is that being out of world, as we would say in I7 terms, is associated not with an action as such but with the command verb triggering it. (This in practice caused no trouble since we never used, say, the word SAVE for both saving the game and saving, I don't know, box top coupons.) The state of `meta` returned by the I6 parser does not quite correspond to I7's "out of world" concept, so we will alter it in a few cases.

Some of these conventions are a little odd-looking now: why not simply have a larger results array, rather than this pile of occasionally used variables? The reasons are purely historical: the I6 parser developed gradually over about a decade.

```
Constant ACTION_PRES = 0;
Constant NO_INPS_PRES = 1;
```

```
Constant INP1_PRES = 2;
Constant INP2_PRES = 3;

[ PARSE_COMMAND_R;
    if (EarlyInTurnSequence == false) rfalse; ! Prevent use outside top level
    not_yet_in_play = false;
    Parser__parse(parser_results);
    TreatParserResults(parser_results);
    rfalse;
];
```

§**8. Treat Parser Results.** We don't quite use the results exactly as they are returned by the parser: we make modifications in a few special cases.

(1) `##MistakeAction` is a valid I6 action, but not an I7 one. It is used to implement "Understand ... as a mistake", which provides a short-cut way for I7 source text to specify responses to mistaken guesses at the syntax expected for commands. It can therefore result from a whole variety of different commands, some of which might be flagged `meta`, others not. We forcibly set the `meta` flag: a mistake in guessing the command always happens out of world.

(2) A command in the form PERSON, TELL ME ABOUT SOMETHING is altered to the action resulting from ASK PERSON ABOUT SOMETHING, so that `##Tell` is converted to `##Ask` in these cases.

```
[ TreatParserResults results;
    if (results-->ACTION_PRES == ##MistakeAction) meta = true;
    if (results-->ACTION_PRES == ##Tell && results-->INP1_PRES == player && actor ~= player) {
        results-->ACTION_PRES = ##Ask;
        results-->INP1_PRES = actor; actor = player;
    }
];
```

§**9. Generate Action Rule.** For what are, again, historical reasons to do with the development of I6, the current action is recorded in a slate of global variables:

(1) `actor` is as above; `action` is the I6 action number or fake action number, though in I7 usage no fake actions should ever reach this point.

(2) `act_requester` is the person requesting that the actor should perform the action, or `nothing` if the action is the actor's own choice. In the command FLOYD, MOP FLOOR, the `act_requester` is the player and the actor is Floyd; but when an action arises from a try phrase in I7, such as "try Floyd mopping the floor", `act_requester` is `nothing` because it is Floyd's own decision to do this. (The computer, of course, represents the will-power of all characters other than the player.)

(3) `inp1` and `inp2` are global variables whose contents mean the same as those of `parser_results-->INP1_PRES` and `parser_results-->INP2_PRES`. (This is not duplication, because actions also arise from "try" rather than the parser.)

(4) The variable `multiflag` is set during the processing of a multiple object list, and clear otherwise. (It is used for instance by the Standard Rules to give more concise reports of some successful actions.) Note that it remains set during any knock-on actions caused by actions in the multiple object list: the following rule is the only place where `multiflag` is set or cleared.

(5) `noun` and `second` are global variables which are equal to `inp1` and `inp2` when the latter hold valid object numbers, and are equal to `nothing` otherwise. (This is not duplication either, because it provides us with type-safe access to objects: there is no KOV which can safely represent `inp1` and `inp2`, but `noun` and `second` are valid for the I7 kind of value "object".)

In the following rule, we create this set of variables for the action or multiple action(s) suggested by the parser: each action is sent on to `BeginAction` for processing. Once done, we reset the above variables in

what might seem an odd way: we allow straightforward actions by the player to remain in the variables, but convert requests to other people to the neutral "waiting" action carried out by the player (which is the zero value for actions). Now, in a better world, we would always erase the action like this, because an action once completed ought to be forgotten. The value of `noun` ought to be visible only during the action's processing.

But in practice many I7 users write "every turn" rules which are predicated on what the turn's main action was: say, "Every turn when going: ..." The every turn stage is not until later in the turn sequence, so such rules can only work if we keep the main parser-generated action of the turn in the action variables when we finish up here: so that's what we do. (Note that `BeginAction` preserves the values of the action variables, storing copies on the stack, so whatever may have happened during processing, we finish this routine with the same action variable values that we set at the beginning.)

Finally, note that an out of world action stops the turn sequence early, at the end of action generation: this is what prevents the time of day advancing, every turn rules from firing, and so forth – see the Standard Rules.

```
[ GENERATE_ACTION_R i j k l;
    if (EarlyInTurnSequence == false) rfalse; ! Prevent use outside top level
    EarlyInTurnSequence = false;
    action = parser_results-->ACTION_PRES;
    act_requester = nothing; if (actor ~= player) act_requester = player;
    inp1 = 0; inp2 = 0; multiflag = false;
    if (parser_results-->NO_INPS_PRES >= 1) {
        inp1 = parser_results-->INP1_PRES; if (inp1 == 0) multiflag = true;
    }
    if (parser_results-->NO_INPS_PRES >= 2) {
        inp2 = parser_results-->INP2_PRES; if (inp2 == 0) multiflag = true;
    }
    if (inp1 == 1) {
        noun = special_number1;
    } else noun = inp1;
    if (inp2 == 1) {
        if (inp1 == 1) second = special_number2; else second = special_number1;
    } else second = inp2;
    if (multiflag) {
        if (multiple_object-->0 == 0) { L__M(##Miscellany, 2); return; }
        if (toomany_flag) { toomany_flag = false; L__M(##Miscellany, 1); }
        GenerateMultipleActions();
        multiflag = false;
    } else BeginAction(action, noun, second);
    if ((actor ~= player) || (act_requester)) action = ##Wait;
    actor = player; act_requester = 0;
    if (meta) { RulebookSucceeds(); rtrue; }
    rfalse;
];
```

§**10. Generate Multiple Actions.** So this routine is used to issue the individual actions necessary when a multiple object list has been supplied as either the noun or second noun part of an action generated by the parser. Note that we stop processing the list in the event of the game ending, or of the `location` variable changing its value, which can happen either through movement of the player, or through passage from darkness to light or vice versa.

We use `RunParagraphOn` to omit skipped lines as paragraph breaks between the results from any item in the list: this is both more condensed on screen in ordinary lists, and might allow the user to play tricks such as gathering up reports from a list and delivering them later in some processed way.

```
[ GenerateMultipleActions initial_location k item;
    initial_location = location;
    for (k=1: k<=multiple_object-->0: k++) {
        item = multiple_object-->k;
        RunParagraphOn();
        if (inp1 == 0) { inp1 = item; BeginAction(action, item, second, item); inp1 = 0; }
        else { inp2 = item; BeginAction(action, noun, item, item); inp2 = 0; }
        if (deadflag) return;
        if (location ~= initial_location) { L__M(##Miscellany, 51); return; }
    }
];
```

§**11. Timed Events Rule.** A timed event is a rule stored in the `TimedEventsTable`, an I6 table array: zero entries in this table are ignored, and the sequence is significant only if more than one event goes off at the same moment, in which case earlier entries go off first. Each rule in the table has a corresponding timer value in `TimedEventTimesTable`. If this is negative, it represents a number of turns to go before the event happens – or properly speaking, the number of times the timed events rule is invoked. Otherwise the timer value must be a valid time of day at which the event happens (note that valid times are all non-negative integers). We allow a bracket of 30 minutes after the event time proper; this is designed to cope with situations in which the user sets some timed events, then advances the clock by hand (or uses a long step time, say in which each turn equates to 20 minutes).

Because an event is struck out of the table just before it is fired, it will not continue to go off the rest of the half-hour. Moreover, because the striking out happens *before* rather than after the rule fires, a rule can re-time itself to go off again later, somewhat like the snooze feature on an alarm clock, without the risk of it going off again immediately in the same use of the timed events rule: there is guaranteed to be a blank slot in the timer array at or before the current position because we have just blanked one.

```
[ TIMED_EVENTS_R i event_timer fire rule;
    for (i=1: i<=(TimedEventsTable-->0): i++)
        if ((rule=TimedEventsTable-->i) ~= 0) {
            event_timer = TimedEventTimesTable-->i; fire = false;
            if (event_timer<0) {
                (TimedEventTimesTable-->i)++;
                if (TimedEventTimesTable-->i == 0) fire = true;
            } else {
                if ((the_time >= event_timer) && (the_time < event_timer+30)) fire = true;
            }
            if (fire) {
                TimedEventsTable-->i = 0;
                ProcessRulebook(rule);
            }
        }
    rfalse;
];
```

§**12. Setting Timed Events.** This is the corresponding routine which adds events to the timer tables, and is used to define phrases like "the cuckoo clock explodes in 7 turns from now" or "the cuckoo clock explodes at 4 PM". Here the `rule` would be "cuckoo clock explodes", and the `event_time` would either be 4 PM with `absolute_time` set, or simply 7 with `absolute_time` clear.

Note that the same event can occur only once in the timer tables: a new setting for its firing overwrites an old one. (This ensures that the table does not slowly balloon in size if the user has not been careful to ensure that events always fire.)

```
[ SetTimedEvent rule event_time absolute_time i b;
    for (i=1: i<=(TimedEventsTable-->0): i++) {
        if (rule == TimedEventsTable-->i) { b=i; break; }
        if ((b==0) && (TimedEventsTable-->i == 0)) b=i;
    }
    if (b==0) return RunTimeProblem(RTP_TOOMANYEVENTS);
    TimedEventsTable-->b = rule;
    if (absolute_time) TimedEventTimesTable-->b = event_time;
    else TimedEventTimesTable-->b = -event_time;
];
```

§**13. Setting Time Of Day.** This is the old I6 library routine `SetTime`, which is no longer used in I7 at present; but might be, some day.

```
Global time_step;
[ SetTime t s;
    the_time = t; time_rate = s; time_step = 0;
    if (s < 0) time_step = 0-s;
];
```

§**14. Advance Time Rule.** This rule advances the two measures of the passing of time: the number of `turns` of play, and `the_time` of day.

```
[ ADVANCE_TIME_R;
    turns++;
    if (the_time ~= NULL) {
        if (time_rate >= 0) the_time = the_time+time_rate;
        else {
            time_step--;
            if (time_step == 0) {
                the_time++;
                time_step = -time_rate;
            }
        }
        the_time = the_time % TWENTY_FOUR_HOURS;
    }
    rfalse;
];
```

§**15. Note Object Acquisitions Rule.** See the Standard Rules for comment on this.

```
[ NOTE_OBJECT_ACQUISITIONS_R obj;
    objectloop (obj in player) give obj moved ~concealed;
    #Ifdef RUCKSACK_CLASS;
    objectloop (obj in player)
        if (obj ofclass RUCKSACK_CLASS)
            SACK_OBJECT = obj;
    objectloop (obj ofclass RUCKSACK_CLASS && obj provides component_parent
        && obj.component_parent == player)
        SACK_OBJECT = obj;
    #Endif;
    rfalse;
];
```

§**16. Resurrect Player If Asked Rule.** If a rule in the "when play ends" rulebook set `resurrect_please`, by executing the "resume the game" phrase, then this is where we notice that: making the shutdown rulebook succeed then tells `Main` to fall back into the turn sequence.

```
[ RESURRECT_PLAYER_IF_ASKED_R;
    if (resurrect_please) { RulebookSucceeds(); resurrect_please = false; deadflag = 0; rtrue; }
    rfalse;
];
```

§**17. Ask The Final Question Rule.** And so we come to the bittersweet end: we ask the final question endlessly, until the player gives a reply which takes drastic enough action to destroy the current execution context in the VM, for instance by typing QUIT, RESTART, UNDO or RESTORE. The question and answer are all managed by the activity, which is defined in I7 source text in the Standard Rules.

```
[ ASK_FINAL_QUESTION_R;
    print "^";
    while (true) {
        CarryOutActivity(DEALING_WITH_FINAL_QUESTION_ACT);
        DivideParagraphPoint();
    }
];
```

§**18. Read The Final Answer Rule.** This erases the current command, so is a technique we couldn't use during actual play, but here commands are but a distant memory. So we can use the same buffers for the final question as for game commands.

```
[ READ_FINAL_ANSWER_R;
    DrawStatusLine();
    KeyboardPrimitive(buffer, parse);
    players_command = 100 + WordCount();
    num_words = WordCount();
    wn = 1;
    rfalse;
];
```

§**19. Immediately Restart VM Rule.** Now for four rules acting on typical responses to the final question.

```
[ IMMEDIATELY_RESTART_VM_R; @restart; ];
```

§**20. Immediately Restore Saved Game Rule.** It is almost certainly unnecessary to set `actor` to `player` here, but we do so just in case, because `RESTORE_THE_GAME_R` is protected against doing anything when it thinks it might have been called erroneously through a command like "DAPHNE, RESTORE". (Out of world actions should never be carried out that way, but again, it's a precaution.)

```
[ IMMEDIATELY_RESTORE_SAVED_R; actor = player; RESTORE_THE_GAME_R(); ];
```

§**21. Immediately Quit Rule.**

```
[ IMMEDIATELY_QUIT_R; @quit; ];
```

§**22. Immediately Undo Rule.** An UNDO is disallowed when `turns` is 1, because there is nothing to revert to: but suppose the player died or won as a result of the very first command? Then the game will be over with `turns` equal to 1, but UNDO disallowed, even though there is a saved state to revert to, captured just before that command was typed. To prevent this, we increment `turns` to include the one only partially completed, but only if a command was actually typed. (If the player died as a result of a monstrously unfair rule applied before the very first command had been typed, UNDO is indeed impossible, and `turns` is left at 1.)

```
[ IMMEDIATELY_UNDO_R;
    if (not_yet_in_play == false) turns++;
    Perform_Undo();
    if (not_yet_in_play == false) turns--;
];
```

§**23. Print Obituary Headline Rule.** Finally, definitions of three primitive rules for the "printing the player's obituary" activity.

```
[ PRINT_OBITUARY_HEADLINE_R;
    print "^^    ";
    VM_Style(ALERT_VMSTY);
    print "***";
    if (deadflag == 1) L__M(##Miscellany, 3);
    if (deadflag == 2) L__M(##Miscellany, 4);
    if (deadflag ~= 0 or 1 or 2)  {
        print " ";
        if (deadflag ofclass Routine) (deadflag)();
        if (deadflag ofclass String) print (string) deadflag;
        print " ";
    }
    print "***";
    VM_Style(NORMAL_VMSTY);
    print "^^"; #Ifndef NO_SCORE; print "^"; #Endif;
    rfalse;
];
```

§24. Print Final Score Rule.

```
[ PRINT_FINAL_SCORE_R;
    #Ifndef NO_SCORING; ANNOUNCE_SCORE_R(); #Endif;
    rfalse;
];
```

§25. Display Final Status Line Rule.

```
[ DISPLAY_FINAL_STATUS_LINE_R;
    sline1 = score; sline2 = turns;
    rfalse;
];
```

Actions Template B/actt

Purpose

To try actions by people in the model world, processing the necessary rulebooks.

---

§**1. Summary.** To review: an action is an impulse to do something by a person in the model world. Commands such as DROP POTATO are converted into actions ("dropping the Idaho potato"); sometimes they succeed, sometimes they fail. While they run, the fairly complicated details are stored in a suite of I6 global variables such as `actor`, `noun`, `inp1`, and so on (see "OrderOfPlay.i6t" for details); the running of an action is mainly a matter of processing many rulebooks, chief among them they "action processing rules".

In general, actions can come from five different sources:

(i) As a result of parsing the player's command: there are actually two ways this can happen, one if the command calls for a single action, and another if it calls for a whole run of them (like TAKE ALL). See the rules in "OrderOfPlay.i6t".
(ii) From an I7 "try" phrase, in which case `TryAction` is called.
(iii) From an I6 angle-bracket-notation such as `<Wait>`, though this is a syntax which is deprecated now, and is never normally used in I7. The I6 compiler converts such a syntax into a call to the `R_Process` below.
(iv) Through conversion of an existing action. For instance, "removing the cup from the table" is converted in the Standard Rules to "taking the cup". This is done via a routine called `GVS_Convert`.
(v) When a request is successful, the "carry out requested actions" rule turns the original action – a request by the player, such as is produced by CHOPIN, PLAY POLONAISE – into an action by the person asked, such as "Chopin playing the Polonaise".

Certain exceptional cases can arise for other reasons:

(vi) Implicit taking actions are generated by the "carrying requirements rule" when the actor tries something which requires him to be holding an item which he can see, but is not currently holding.
(vii) A partial but intentionally incomplete form of the "looking" action is generated when describing the new location at the end of a "going" action.

In every case except (vii), the action is carried out by `BeginAction`, the single routine which unifies all of these approaches. Except the last one.

This segment of the template is divided into two: first, the I6 code needed for (i) to (vii), the alternative ways for actions to begin; and secondly the common machinery into which all actions eventually pass.

§**2. Action Data.** This is perhaps a good place to document the `ActionData` array, a convenient table of metadata about the actions. Since this is compiled by NI, the following structure can't be modified here without making matching changes in NI. `ActionData` is an I6 `table` containing a series of fixed-length records, one on each action.

The routine `FindAction` locates the record in this table for a given action number, returning its word offset within the table: the argument -1 means "the current action".

```
Constant AD_ACTION = 0; ! The I6 action number (0 to 4095)
Constant AD_REQUIREMENTS = 1; ! Such as requiring light; a bitmap, see below
Constant AD_NOUN_KOV = 2; ! Kind of value of the first noun
Constant AD_SECOND_KOV = 3; ! Kind of value of the second noun
Constant AD_NAME_BASE = 4; ! Up to five words of a name, padded with nulls
Constant AD_VARIABLES_CREATOR = 9; ! Routine to initialise variables owned
Constant AD_VARIABLES_ID = 10; ! Frame ID for variables owned by action

Constant AD_NAME_LENGTH = 5;
Constant AD_RECORD_SIZE = 11;

[ FindAction fa t;
    if (fa == -1) fa = action;
    t = 1;
    while (t <= ActionData-->0) {
        if (fa == ActionData-->t) return t;
        t = t + AD_RECORD_SIZE;
    }
    rfalse;
];
```

§**3. Requirements Bitmap.** As noted above, the `AD_REQUIREMENTS` field is a bitmap of flags for various possible action requirements:

```
Constant TOUCH_NOUN_ABIT   = $$00000001;
Constant TOUCH_SECOND_ABIT = $$00000010;
Constant LIGHT_ABIT        = $$00000100;
Constant NEED_NOUN_ABIT    = $$00001000;
Constant NEED_SECOND_ABIT  = $$00010000;
Constant OUT_OF_WORLD_ABIT = $$00100000;
Constant CARRY_NOUN_ABIT   = $$01000000;
Constant CARRY_SECOND_ABIT = $$10000000;

[ NeedToCarryNoun;       return TestActionMask(CARRY_NOUN_ABIT); ];
[ NeedToCarrySecondNoun; return TestActionMask(CARRY_SECOND_ABIT); ];
[ NeedToTouchNoun;       return TestActionMask(TOUCH_NOUN_ABIT); ];
[ NeedToTouchSecondNoun; return TestActionMask(TOUCH_SECOND_ABIT); ];
[ NeedLightForAction;    return TestActionMask(LIGHT_ABIT); ];

[ TestActionMask match mask at;
    at = FindAction(-1);
    if (at == 0) rfalse;
    mask = ActionData-->(at+AD_REQUIREMENTS);
    if (mask & match) rtrue;
    rfalse;
];
```

§**4. Try Action.** This is method (ii) in the summary above.

```
[ TryAction req by ac n s stora tbits saved_command text_of_command;
    if (stora) return STORED_ACTION_TY_New(ac, n, s, by, req, stora);
    tbits = req & (16+32);
    req = req & 1;
    @push actor; @push act_requester; @push inp1; @push inp2; @push parsed_number;
    actor = by; if (req) act_requester = player; else act_requester = 0;
    by = FindAction(ac);
    if (by) {
        if (ActionData-->(by+AD_NOUN_KOV) == OBJECT_TY) inp1 = n;
        else { inp1 = 1; parsed_number = n; }
        if (ActionData-->(by+AD_SECOND_KOV) == OBJECT_TY) inp2 = s;
        else { inp2 = 1; parsed_number = s; }
        if (((ActionData-->(by+AD_NOUN_KOV) == UNDERSTANDING_TY) ||
            (ActionData-->(by+AD_SECOND_KOV) == UNDERSTANDING_TY)) && (tbits)) {
            saved_command = INDEXED_TEXT_TY_Create();
            INDEXED_TEXT_TY_Cast(players_command, SNIPPET_TY, saved_command);
            text_of_command = INDEXED_TEXT_TY_Create();
            INDEXED_TEXT_TY_Cast(parsed_number, TEXT_TY, text_of_command);
            SetPlayersCommand(text_of_command);
            if (tbits == 16) {
                n = players_command; inp1 = 1; parsed_number = players_command;
            } else {
                s = players_command; inp2 = 1; parsed_number = players_command;
            }
            BlkFree(text_of_command);
            @push consult_from; @push consult_words;
            consult_from = 1; consult_words = parsed_number - 100;
        }
    }
    BeginAction(ac, n, s, 0, true);
    if (saved_command) {
        @pull consult_words; @pull consult_from;
        SetPlayersCommand(saved_command);
        BlkFree(saved_command);
    }
    @pull parsed_number; @pull inp2; @pull inp1; @pull act_requester; @pull actor;
    TrackActions(true);
];
```

§**5. I6 Angle Brackets.** This is method (iii) in the summary above. The routine here has slightly odd conventions and a curious name which would take too long to explain: neither can be changed without amending the veneer code within the I6 compiler.

```
[ R_Process a i j;
    @push inp1; @push inp2;
    inp1 = i; inp2 = j; BeginAction(a, i, j);
    @pull inp2; @pull inp1;
];
```

§**6. Conversion.** This is method (iv) in the summary above.

```
Global converted_action_outcome = -1;
[ GVS_Convert ac n s;
    converted_action_outcome = BeginAction(ac, n, s);
    rtrue;
];
[ ConvertToGoingWithPush i oldrm newrm infl;
    i=noun;
    if (IndirectlyContains(noun, actor) == false) { move i to actor; infl = true; }
    move_pushing = i;
    oldrm = LocationOf(noun);
    BeginAction(##Go, second);
    newrm = LocationOf(actor);
    move_pushing = nothing; move i to newrm;
    if (newrm ~= oldrm) {
        if (IndirectlyContains(i, player)) TryAction(0, player, ##Look, 0, 0);
        RulebookSucceeds();
    } else RulebookFails();
];
```

§**7. Implicit Take.** This is method (vi) in the summary above.

```
[ ImplicitTake obj ks;
    if (actor == player) L__M(##Miscellany, 69, obj);
    else L__M(##Miscellany, 68, obj);
    ClearParagraphing();
    @push keep_silent; keep_silent = true;
    if (act_requester) TryAction(true, actor, ##Take, obj, nothing);
    else TryAction(false, actor, ##Take, obj, nothing);
    @pull keep_silent;
    if (obj in actor) rtrue;
    rfalse;
];
```

§**8. Look After Going.** This is method (vii) in the summary above.

Fundamentally, room descriptions arise through looking actions, but they are also printed after successful going actions, with a special form of paragraph break (see "Printing.i6t" for an explanation of this). Room descriptions through looking are always given in full, unless we have SUPERBRIEF mode set.

```
[ LookAfterGoing;
    GoingLookBreak();
    AbbreviatedRoomDescription();
];
```

§**9. Abbreviated Room Description.** This is used when we want a room description with the same abbreviation conventions as after a going action, and we don't quite want a looking action fully to take place. We nevertheless want to be sure that the action variables for looking exist, and in particular, we want to set the "room-describing action" variable to the action which was prevailing when the room description was called for. We also set "abbreviated form allowed" to "true": when the ordinary looking action is running, this is "false".

The actual description occurs during `LookSub`, which is the specific action processing stage for the "looking" action: thus, we use the check, carry out, after and report rules as if we were "looking", but are unaffected by before or instead rules.

Uniquely, this pseudo-action does not use `BeginAction`: it works only through the specific action processing rules, not the main action-processing ones, though that is not easy to see from the code below because it is hidden in the call to `LookSub`. The `-Sub` suffix is an I6 usage identifying this as the routine to go along with the action `##Look`, and so it is, but it looks nothing like the `LookSub` of the old I6 library. NI compiles `-Sub` routines like so:

```
[ LookSub; return GenericVerbSub(153,154,155); ];
```

(with whatever rulebook numbers are appropriate). `GenericVerbSub` then runs through the specific action processing stage.

```
[ AbbreviatedRoomDescription  prior_action pos frame_id;
    prior_action = action;
    action = ##Look;
    pos = FindAction(##Look);
    if ((pos) && (ActionData-->(pos+AD_VARIABLES_CREATOR))) {
        frame_id = ActionData-->(pos+AD_VARIABLES_ID);
        Mstack_Create_Frame(ActionData-->(pos+AD_VARIABLES_CREATOR), frame_id);
        ProcessRulebook(SETTING_ACTION_VARIABLES_RB);
        (MStack-->MstVO(frame_id, 0)) = prior_action; ! "room-describing action"
        (MStack-->MstVO(frame_id, 1)) = true; ! "abbreviated form allowed"
    }
    LookSub(); ! The I6 verb routine for "looking"
    if (frame_id) Mstack_Destroy_Frame(ActionData-->(pos+AD_VARIABLES_CREATOR), frame_id);
    action = prior_action;
];
```

§**10. Begin Action.** We now begin the second half of the segment: the machinery which handles all actions.

The significance of 4096 here is that this is how I6 distinguishes genuine actions – numbered upwards in order of creation – from what I6 calls "fake actions" – numbered upwards from 4096. Fake actions are hardly used at all in I7, and certainly shouldn't get here, but it's possible nonetheless using I6 angled-brackets, so... In other respects all we do is to save details of whatever current action is happening onto the stack, and then call `ActionPrimitive`.

```
[ BeginAction a n s moi notrack  rv;
    ChronologyPoint();
    @push action; @push noun; @push second; @push self; @push multiple_object_item;
    action = a; noun = n; second = s; self = noun; multiple_object_item = moi;
    if (action < 4096) rv = ActionPrimitive();
    @pull multiple_object_item; @pull self; @pull second; @pull noun; @pull action;
    if (notrack == false) TrackActions(true);
    return rv;
];
```

§**11. Action Primitive.** This is somewhat different from the I6 library counterpart which gives it its name, but the idea is the same. It has no arguments at all: everything it needs to know is now stored in global variables. The routine looks long, but really contains little: it's all just book-keeping, printing debugging information if ACTIONS is in force, etc., with all of the actual work delegated to the action processing rulebook.

We use a rather sneaky device to handle out-of-world actions, those for which the `meta` flag is set: we make it look to the system as if the "action processing rulebook" is being followed, so that all its variables are created and placed in scope, but at the crucial moment we descend to the specific action processing rules directly instead of processing the main rulebook. This is what short-circuits out of world actions and protects them from before and instead rules: see the Standard Rules for more discussion of this.

```
[ ActionPrimitive  rv p1 p2 p3 p4 p5 frame_id;
    MStack_CreateRBVars(ACTION_PROCESSING_RB);
    if ((keep_silent == false) && (multiflag == false)) DivideParagraphPoint();
    reason_the_action_failed = 0;
    frame_id = -1;
    p1 = FindAction(action);
    if ((p1) && (ActionData-->(p1+AD_VARIABLES_CREATOR))) {
        frame_id = ActionData-->(p1+AD_VARIABLES_ID);
        Mstack_Create_Frame(ActionData-->(p1+AD_VARIABLES_CREATOR), frame_id);
    }
    if (ActionVariablesNotTypeSafe()) {
        if (frame_id ~= -1)
            Mstack_Destroy_Frame(ActionData-->(p1+AD_VARIABLES_CREATOR), frame_id);
        MStack_DestroyRBVars(ACTION_PROCESSING_RB);
        return;
    }
    ProcessRulebook(SETTING_ACTION_VARIABLES_RB);
    #IFDEF DEBUG;
    if ((trace_actions) && (FindAction(-1))) {
        print "["; p1=actor; p2=act_requester; p3=action; p4=noun; p5=second;
        DB_Action(p1,p2,p3,p4,p5);
        print "]^"; ClearParagraphing();
    }
    ++debug_rule_nesting;
    #ENDIF;
    TrackActions(false);
    BeginFollowRulebook();

    rfalse;
];
```

§**12. Type Safety.** Some basic action requirements have to be met before we can go any further: if they aren't, then it isn't type-safe even to run the action processing rulebook.

(i) For an out of world action, we set the `meta` flag. Otherwise:

(ii) If either the noun or second noun is a topic, then this is an action arising from parsing (such actions do not arise through the "try" phrase, unless by stored actions in which case this has all happened before and doesn't need to be done again) – the parser places details of which words make up the topic in the I6 global variables `consult_words` and `consult_from`. We convert them to a valid I7 snippet value.

(iii) If either the first or second noun is supposed to be an object but seems here to be a value, or vice versa, we stop with a parser error. (This should be fairly difficult to provoke: NI's type-checking will make it difficult to arrange without I6 subterfuges.)

(iv) If either the first or second noun is supposed to be an object and required to exist, yet is missing, we use the "supplying a missing noun" or "supplying a missing second noun" activities to fill the void.

We return `true` if type safety is violated, `false` if all is well.

```
[ ActionVariablesNotTypeSafe mask noun_kova second_kova at;
    at = FindAction(-1); if (at == 0) rfalse; ! For any I6-defined actions
    mask = ActionData-->(at+AD_REQUIREMENTS);
    if (mask & OUT_OF_WORLD_ABIT) { meta = 1; rfalse; }
    noun_kova = ActionData-->(at+AD_NOUN_KOV);
    second_kova = ActionData-->(at+AD_SECOND_KOV);
    !print "at = ", at, " nst = ", noun_kova, "^";
    !print "consult_from = ", consult_from, " consult_words = ", consult_from, "^";
    !print "inp1 = ", inp1, " noun = ", noun, "^";
    !print "inp2 = ", inp2, " second = ", second, "^";
    !print "sst = ", second_kova, "^";
    if (noun_kova == {-value:SNIPPET_TY} or {-value:UNDERSTANDING_TY}) {
        if (inp1 ~= 1) { inp2 = inp1; second = noun; }
        parsed_number = 100*consult_from + consult_words;
        inp1 = 1; noun = parsed_number;
    }
    if (second_kova == {-value:SNIPPET_TY} or {-value:UNDERSTANDING_TY}) {
        parsed_number = 100*consult_from + consult_words;
```

```
        inp2 = 1; second = parsed_number;
    }

            }
        }
        if (((mask & NEED_SECOND_ABIT) == 0) && (second ~= nothing)) {
            return L__M(##Miscellany, 66); }
    }
    rfalse;
];
```

§**13. Basic Visibility Rule.** This is one of the I6 primitive rules in the action processing rulebook: see the account in the Standard Rules for details.

Note that this rule only blocks the player from acting in darkness: this is because light is only reckoned from the player's perspective in any case, so that it would be unfair to apply the rule to any other person.

```
[ BASIC_VISIBILITY_R;
    if (act_requester) rfalse;
    if ((NeedLightForAction()) &&
        (actor == player) &&
        (ProcessRulebook(VISIBLE_RB)) &&
        (RulebookSucceeded())) {
        BeginActivity(REFUSAL_TO_ACT_IN_DARK_ACT);
        if (ForActivity(REFUSAL_TO_ACT_IN_DARK_ACT)==false) L__M(##Miscellany, 17);
        EndActivity(REFUSAL_TO_ACT_IN_DARK_ACT);
        reason_the_action_failed = BASIC_VISIBILITY_R;
        RulebookFails();
        rtrue;
    }
    rfalse;
];
```

§**14. Basic Accessibility Rule.** This is one of the I6 primitive rules in the action processing rulebook: see the account in the Standard Rules for details.

```
[ BASIC_ACCESSIBILITY_R mask at;
    if (act_requester) rfalse;
    at = FindAction(-1);
    if (at == 0) rfalse;
    mask = ActionData-->(at+AD_REQUIREMENTS);
    if ((mask & TOUCH_NOUN_ABIT) && noun && (inp1 ~= 1)) {
        if (noun ofclass K3_direction) {
            RulebookFails();
            reason_the_action_failed = BASIC_ACCESSIBILITY_R;
            if (actor~=player) rtrue;
            return L__M(##Miscellany, 67);
        }
        if (ObjectIsUntouchable(noun, (actor~=player), FALSE, actor)) {
            RulebookFails();
            reason_the_action_failed = BASIC_ACCESSIBILITY_R;
            rtrue;
        }
    }
    if ((mask & TOUCH_SECOND_ABIT) && second && (inp2 ~= 1)) {
        if (second ofclass K3_direction) {
            RulebookFails();
            reason_the_action_failed = BASIC_ACCESSIBILITY_R;
            if (actor~=player) rtrue;
            return L__M(##Miscellany, 67);
        }
        if (ObjectIsUntouchable(second, (actor~=player), FALSE, actor)) {
            RulebookFails();
            reason_the_action_failed = BASIC_ACCESSIBILITY_R;
```

```
            rtrue;
        }
    }
    rfalse;
];
```

§**15. Carrying Requirements Rule.** This is one of the I6 primitive rules in the action processing rulebook: see the account in the Standard Rules for details.

```
[ CARRYING_REQUIREMENTS_R mask at;
    at = FindAction(-1);
    if (at == 0) rfalse;
    mask = ActionData-->(at+AD_REQUIREMENTS);
    if ((mask & TOUCH_NOUN_ABIT) && noun && (inp1 ~= 1)) {
        if ((mask & CARRY_NOUN_ABIT) && (noun notin actor)) {
            BeginActivity(IMPLICITLY_TAKING_ACT, noun);
            if (ForActivity(IMPLICITLY_TAKING_ACT, noun)==false)
                ImplicitTake(noun);
            EndActivity(IMPLICITLY_TAKING_ACT, noun);
            !if (act_requester) rfalse;
            if (noun notin actor) {
                RulebookFails();
                reason_the_action_failed = CARRYING_REQUIREMENTS_R;
                rtrue;
            }
        }
    }
    if ((mask & TOUCH_SECOND_ABIT) && second && (inp2 ~= 1)) {
        if ((mask & CARRY_SECOND_ABIT) && (second notin actor)) {
            BeginActivity(IMPLICITLY_TAKING_ACT, second);
            if (ForActivity(IMPLICITLY_TAKING_ACT, second)==false)
                ImplicitTake(second);
            EndActivity(IMPLICITLY_TAKING_ACT, second);
            !if (act_requester) rfalse;
            if (second notin actor) {
                RulebookFails();
                reason_the_action_failed = CARRYING_REQUIREMENTS_R;
                rtrue;
            }
        }
    }
    rfalse;
];
```

§16. Requested Actions Require Persuasion Rule. This is one of the I6 primitive rules in the action processing rulebook: see the account in the Standard Rules for details.

```
[ REQUESTED_ACTIONS_REQUIRE_R;
    if ((actor ~= player) && (act_requester)) {
        @push say__p;
        say__p = 0;
        ProcessRulebook(PERSUADE_RB);
        if (RulebookSucceeded() == false) {
            if (say__p == FALSE) L__M(##Miscellany, 72, actor);
            RulebookFails(); rtrue;
        }
        @pull say__p;
    }
    rfalse;
];
```

§17. Carry Out Requested Actions Rule. This is one of the I6 primitive rules in the action processing rulebook: see the account in the Standard Rules for details.

```
[ CARRY_OUT_REQUESTED_ACTIONS_R rv;
    if ((actor ~= player) && (act_requester)) {
        @push act_requester; act_requester = nothing;
        rv = BeginAction(action, noun, second);
        if ((meta) || (rv == false)) {
            if (ProcessRulebook(UNSUCCESSFUL_ATTEMPT_RB) == false) L__M(##Miscellany, 58);
        }
        @pull act_requester;
        ActRulebookSucceeds();
        rtrue;
    }
    rfalse;
];
```

§18. Generic Verb Subroutine. In I6, actions are carried out by routines with names like `TakeSub`, consisting of `-Sub` tacked on to the action name `Take`. `Sub` stands for "subroutine": this is all a convention going back to Inform 1, which was in 1993 practically an assembler. In the I6 code generated by I7, every `-Sub` routine corresponding to an I7 action consists only of a call to `GenericVerbSub` which specifies the three rulebooks it owns: its check, carry out and report rulebooks.

```
Array Details_of_Specific_Action-->5;
[ GenericVerbSub ch co re vis rv;
    @push converted_action_outcome;
    converted_action_outcome = -1;
    Details_of_Specific_Action-->0 = true;
    if (meta) Details_of_Specific_Action-->0 = false;
    Details_of_Specific_Action-->1 = keep_silent;
    Details_of_Specific_Action-->2 = ch; ! Check rules for the action
    Details_of_Specific_Action-->3 = co; ! Carry out rules for the action
    Details_of_Specific_Action-->4 = re; ! Report rules for the action
    ProcessRulebook(SPECIFIC_ACTION_PROCESSING_RB, 0, true);
```

```
    if ((RulebookFailed()) && (converted_action_outcome == 1)) ActRulebookSucceeds();
    @pull converted_action_outcome;
    rtrue;
];
```

§**19. Work Out Details Of Specific Action Rule.** This is one of the I6 primitive rules in the specific action processing rulebook, and it's basically a trick to allow information known to the `GenericVerbSub` routine to be passed down as rulebook variables for the specific action-processing rules – in effect allowing us to pass not one but five parameters to the rulebook: the out-of-world and silence flags, plus the three specific rulebooks needed to process the action.

```
[ WORK_OUT_DETAILS_OF_SPECIFIC_R;
    MStack-->MstVO(SPECIFIC_ACTION_PROCESSING_RB, 0) = Details_of_Specific_Action-->0;
    MStack-->MstVO(SPECIFIC_ACTION_PROCESSING_RB, 1) = Details_of_Specific_Action-->1;
    MStack-->MstVO(SPECIFIC_ACTION_PROCESSING_RB, 2) = Details_of_Specific_Action-->2;
    MStack-->MstVO(SPECIFIC_ACTION_PROCESSING_RB, 3) = Details_of_Specific_Action-->3;
    MStack-->MstVO(SPECIFIC_ACTION_PROCESSING_RB, 4) = Details_of_Specific_Action-->4;
    rfalse;
];
```

§**20. Actions Bitmap.** This is a fairly large bitmap recording which actions have succeeded thus far on which nouns. It was to some extent an early attempt at implementing a past-tense system; I'm not at all sure it was successful, since it is hindered by certain restrictions – it only records action/noun combinations, for instance, and the notion of "success" is a vexed one for actions anyway. There is a clearly defined meaning, but it doesn't always correspond to what the user might expect, which is unfortunate.

```
[ TestActionBitmap obj act i j k bitmap;
    if (obj == nothing) bitmap = ActionHappened;
    else {
        if (~~(obj provides action_bitmap)) rfalse;
        bitmap = obj.&action_bitmap;
    }
    if (act == -1) return (((bitmap->0) & 1) ~= 0);
    for (i=0, k=2; i<ActionCount; i++) {
        if (act == ActionCoding-->i) {
            return (((bitmap->j) & k) ~= 0);
        }
        k = k*2; if (k == 256) { k = 1; j++; }
    }
    rfalse;
];
[ UpdateActionBitmap;
    SetActionBitmap(noun, action);
    if (action == ##Go) SetActionBitmap(location, ##Enter);
];
[ SetActionBitmap obj act i j k bitmap;
    for (i=0, k=2; i<ActionCount; i++) {
        if (act == ActionCoding-->i) {
            if (obj provides action_bitmap) {
                bitmap = obj.&action_bitmap;
                bitmap->0 = (bitmap->0) | 1;
```

```
                bitmap->j = (bitmap->j) | k;
            }
            ActionHappened->0 = (ActionHappened->0) | 1;
            ActionHappened->j = (ActionHappened->j) | k;
        }
        k = k*2; if (k == 256) { k = 1; j++; }
    }
];
```

§**21. Printing Actions.** This is really for debugging purposes, but also provides us with a way to print a stored action, for instance, or to print an action-name value. (For instance, printing an action-name might result in "taking"; printing a whole action might produce "Henry taking the grapefruit".)

```
[ SayActionName act; DB_Action(0, 0, act, 0, 0, 2); ];
[ DA_Name n; if (n ofclass K3_direction) print (name) n; else print (the) n; ];
[ DA_Topic x a b c d i cf cw;
    cw = x%100; cf = x/100;
    print "~";
    for (a=cf:d<cw:d++,a++) {
        wn = a; b = WordAddress(a); c = WordLength(a);
        for (i=b:i<b+c:i++) {
            print (char) 0->i;
        }
        if (d<cw-1) print " ";
    }
    print "~";
];
[ DA_Number n; print n; ];
[ DA_TruthState n; if (n==0) print "false"; else print "true"; ];
[ DB_Action ac acr act n s for_say t l j v c clc;
    if ((for_say == 0) && (debug_rule_nesting > 0))
        print "(", debug_rule_nesting, ") ";
    if ((ac ~= player) && (for_say ~= 2)) {
        if (acr) print "asking ", (the) ac, " to try ";
        else print (the) ac, " ";
    }
    t = FindAction(act);
    if (t) {
        t = t + AD_NAME_BASE; l = t + AD_NAME_LENGTH;
        while ((v = ActionData-->t) ~= NULL) {
            if (v ofclass Routine) {
                if (for_say == 2) {
                    if (ActionData-->(t+1) ~= NULL) {
                        if (clc++ > 0) print " ";
                        print "it";
                    }
                } else {
                    if (clc++ > 0) print " ";
                    if (c==0) { (v)(n); }
                    else { (v)(s); }
                    c++;
                }
```

```
            } else {
                if (clc++ > 0) print " ";
                print (string) v;
            }
            t++;
            if (t == l) break;
        }
        if ((keep_silent) && (for_say == 0)) print " - silently";
    }
];
```

Activities Template B/acvt

Purpose

To run the necessary rulebooks to carry out an activity.

---

§**1. The Activities Stack.** Activities are more like nested function calls than independent processes; they finish in reverse order of starting, and are placed on a stack. This needs only very limited size in practice: 20 might seem a bit low, but making it much higher simply means that oddball bugs in the user's code – where activities recursively cause themselves ad infinitum – will be caught less efficiently.

```
Constant MAX_NESTED_ACTIVITIES = 20;
Global activities_sp = 0;
Array activities_stack --> MAX_NESTED_ACTIVITIES;
Array activity_parameters_stack --> MAX_NESTED_ACTIVITIES;
```

§**2. Rule Debugging Inhibition.** The output from RULES or RULES ALL becomes totally illegible if it is applied even to the activities printing names of objects, so this is inhibited when any such activity is running. `FixInhibitFlag` is called each time the stack changes and ensures that `inhibit_flag` has exactly this meaning.

```
Global inhibit_flag = 0;
Global saved_debug_rules = 0;
[ FixInhibitFlag n act inhibit_rule_debugging;
    for (n=0:n<activities_sp:n++) {
        act = activities_stack-->n;
        if (act == PRINTING_THE_NAME_ACT or PRINTING_THE_PLURAL_NAME_ACT or
            PRINTING_ROOM_DESC_DETAILS_ACT or LISTING_CONTENTS_ACT or
            GROUPING_TOGETHER_ACT) inhibit_rule_debugging = true;
    }
    if ((inhibit_flag == false) && (inhibit_rule_debugging)) {
        saved_debug_rules = debug_rules;
        debug_rules = 0;
    }
    if ((inhibit_flag) && (inhibit_rule_debugging == false)) {
        debug_rules = saved_debug_rules;
    }
    inhibit_flag = inhibit_rule_debugging;
];
```

§**3. Testing Activities.** The following tests whether a given activity `A` is currently running whose parameter-object matches description `desc`, where as usual the description is represented by a routine testing membership, and where zero `desc` means that any parameter is valid.

```
[ TestActivity A desc i;
    for (i=0:i<activities_sp:i++)
        if (activities_stack-->i == A) {
            if (desc == 0) rtrue;
            if ((desc)(activity_parameters_stack-->i)) rtrue;
        }
    rfalse;
];
```

§**4. Emptiness.** An activity is defined by its three rulebooks: it is empty if they are all empty.

```
[ ActivityEmpty A x;
    x = Activity_before_rulebooks-->A;
    if (((rulebooks_array-->x)-->0) ~= NULL) rfalse;
    x = Activity_for_rulebooks-->A;
    if (((rulebooks_array-->x)-->0) ~= NULL) rfalse;
    x = Activity_after_rulebooks-->A;
    if (((rulebooks_array-->x)-->0) ~= NULL) rfalse;
    rtrue;
];
[ RulebookEmpty rb;
    if (((rulebooks_array-->rb)-->0) ~= NULL) rfalse;
    rtrue;
];
```

§**5. Process Activity Rulebook.** This is really much like processing any rulebook, except that `self` is temporarily set to the parameter, and is preserved by the process.

```
[ ProcessActivityRulebook rulebook parameter  rv;
    @push self;
    if (parameter) self = parameter;
    rv = ProcessRulebook(rulebook, parameter, true);
    @pull self;
    if (rv) rtrue;
    rfalse;
];
```

§**6. Carrying Out Activities.** This is a three-stage process; most activities are run by calling the following simple routine, but some are run by calling the three subroutines independently.

```
[ CarryOutActivity A o rv;
    BeginActivity(A, o);
    rv = ForActivity(A, o);
    EndActivity(A, o);
    return rv;
];
```

§**7. Begin.** Note that when an activity based on the conjectural "future action" is being run – in a few parser-related cases, that is – the identity of this action is put temporarily into `action`, and the current value saved while this takes place. That allows rules in the activity rulebooks to have preambles based on the current action, and yet be tested against what is not yet the current action.

```
[ BeginActivity A o x;
    if (activities_sp == MAX_NESTED_ACTIVITIES) return RunTimeProblem(RTP_TOOMANYACTS);
    activity_parameters_stack-->activities_sp = o;
    activities_stack-->(activities_sp++) = A;
    FixInhibitFlag();
    MStack_CreateAVVars(A);
    if (Activity_atb_rulebooks->A) { x = action; action = action_to_be; }
    o = ProcessActivityRulebook(Activity_before_rulebooks-->A, o);
    if (Activity_atb_rulebooks->A) action = x;
    return o;
];
```

§**8. For.**

```
[ ForActivity A o x;
    if (Activity_atb_rulebooks->A) { x = action; action = action_to_be; }
    o = ProcessActivityRulebook(Activity_for_rulebooks-->A, o);
    if (Activity_atb_rulebooks->A) action = x;
    return o;
];
```

§**9. End.**

```
[ EndActivity A o rv x;
    if ((activities_sp > 0) && (activities_stack-->(activities_sp-1) == A)) {
        if (Activity_atb_rulebooks->A) { x = action; action = action_to_be; }
        rv = ProcessActivityRulebook(Activity_after_rulebooks-->A, o);
        if (Activity_atb_rulebooks->A) action = x;
        activities_sp--; FixInhibitFlag();
        MStack_DestroyAVVars(A);
        return rv;
    }
    return RunTimeProblem(RTP_CANTABANDON);
];
```

§**10. Abandon.** For (very) rare cases where an activity must be abandoned midway; such an activity must be being run by calling the three stages individually, and `EndActivity` must not have been called yet.

```
[ AbandonActivity A o;
    if ((activities_sp > 0) && (activities_stack-->(activities_sp-1) == A)) {
        activities_sp--; FixInhibitFlag();
        MStack_DestroyAVVars(A);
        return;
    }
    return RunTimeProblem(RTP_CANTEND);
];
```

Rulebooks Template B/rbt

Purpose

To work through the rules in a rulebook until a decision is made.

§**1. Rule Change Stack.** The rulebook is a fundamental data structure in Inform 7: it's the basic way in which code is organised. The metaphor is that a rulebook is a loose-leaf ring-binder rather than a bound volume: so we can not only tell NI how to bind the rulebooks at compile time, we can also rearrange the pages during use at run-time.

We keep track of such run-time changes not by actually changing the rulebook arrays but by using the "rule change stack". This is a tally of any temporary abolition or modification of rules: thus, before using any rule from a rulebook we need to check that there is no note of its abolition. As the rule change stack gets larger, rule processing gets slower: this is why it's always more efficient to change rulebooks at compile time than at run-time, if there's a choice between the two.

The rule change stack contains 3-word (6 byte) records, a usage code and two operands (normally both rules).

```
Constant RULECHANGE_STACK_SIZE = 501;
Global rulechange_sp = 0;
Array rulechange_stack --> RULECHANGE_STACK_SIZE;

[ PushRuleChange usage rule1 rule2;
    if (rulechange_sp >= RULECHANGE_STACK_SIZE) return RunTimeProblem(RTP_RULESTACK);
    rulechange_stack-->rulechange_sp++ = usage;
    rulechange_stack-->rulechange_sp++ = rule1;
    rulechange_stack-->rulechange_sp++ = rule2;
];
```

§**2. Usage Codes.** The first word of each record indicates a usage type, of which one value is special and indicates the start of a frame. A new frame is opened on the stack each time a new "follow" occurs; recall that this processes a rulebook after consulting procedural rules, which may in turn modify the behaviour of other rules. These frame divisions, therefore, mark local scopes for modifications: anything from the top of the stack down to the topmost frame marker is currently in force.

There are then seven kinds of frame marking different ways in which rules have been modified; and three further values which indicate possible outcomes. In the following, we refer to the record as containing word 1, one of the usage codes below, word 2 and word 3.

(0) `RS_FRAME` marks the lowest point on the stack of a frame. Words 2 and 3 are not used.

(1) `RS_DONOTRUN` marks the rule or rulebook in word 1 as to be ignored.

(2) `RS_RUN` reinstates the rule or rulebook in word 1. This is useful only to reverse the effect of an `RS_DONOTRUN` frame.

(3) `RS_MOVEBEFORE` moves the rule/rulebook in word 1 to immediately before the rule/rulebook in word 2. If the latter is never invoked, nor is the former.

(4) `RS_MOVEAFTER` moves the rule/rulebook in word 1 to immediately after the rule/rulebook in word 2. If the latter is never invoked, nor is the former.

(5) `RS_DONOTUSE` marks the rule/rulebook in word 1 as to be invoked in the normal way, but then have its result (if any) ignored.

(6) `RS_USE` reverses the effect of an earlier `RS_DONOTUSE` frame.

(7) `RS_SUBSTITUTE` moves the rule/rulebook in word 1 so that it is invoked instead of the rule/rulebook in word 2. If the latter is never invoked, nor is the former.

(8) `RS_SUCCEEDS` occurs only exactly above the top of the stack: it is an ephemeral frame wiped out as soon as the stack is used again. It indicates that the most recent rule or rulebook processed ended in success. Word 2 is a flag: `true` means that a value was returned, `false` that it wasn't. If this is `true` then word 3 contains the value.

(9) `RS_FAILS` is similar, but for a failure. Note that failures can also return values.

(10) `RS_NEITHER` is similar except that it cannot return any value, so that words 2 and 3 are meaningless.

```
Constant RS_FRAME       = -1;
Constant RS_DONOTRUN = 1;
Constant RS_RUN = 2;
Constant RS_MOVEBEFORE = 3;
Constant RS_MOVEAFTER = 4;
Constant RS_DONOTUSE = 5;
Constant RS_USE = 6;
Constant RS_SUBSTITUTE = 7;
Constant RS_SUCCEEDS = 8;
Constant RS_FAILS = 9;
Constant RS_NEITHER = 10;
```

§**3. Following.** At the I6 level, there are two ways to invoke a rulebook: we can "follow" it, or simply "process" it. The former is a grander and slightly slower method which contains the latter. The I7 language talks about "considering" and "abiding by" rules and rulebooks, but these aren't handled at the I6 level: they are both achieved by "process" and the difference between the two is a matter of what is done with the result. (See the Standard Rules for the definitions.)

To "follow" a rulebook, we start a new frame, process the procedural rules, then process the rulebook, then clear the frame back off the stack. (To avoid circularity, the procedural rulebook is the only one which is exempted from the procedural rules.)

```
Global rule_frames = 0; ! Number of frames currently in force
Constant MAX_SIMULTANEOUS_FRAMES = 20;
[ FollowRulebook rulebook parameter no_paragraph_skips  rv;
    @push self;
    if ((Protect_I7_Arrays-->0 ~= 16339) || (Protect_I7_Arrays-->1 ~= 12345)) {
        print "^^*** Fatal programming error: I7 arrays corrupted ***^^";
        @quit;
    }
    if (parameter) self = parameter;
    if (rulebook ~= PROCEDURAL_RB) BeginFollowRulebook();
    rv = ProcessRulebook(rulebook, parameter, no_paragraph_skips);
    if (rulebook ~= PROCEDURAL_RB) EndFollowRulebook();
    @pull self;
    if (rv) rtrue;
    rfalse;
];
[ BeginFollowRulebook;
    PushRuleChange(RS_FRAME, RS_FRAME, RS_FRAME);
    rule_frames++;
    if (rule_frames == MAX_SIMULTANEOUS_FRAMES) {
        RunTimeProblem(RTP_TOOMANYRULEBOOKS);
```

```
        rule_frames = -1; ! For recovery: this terminates rulebook processing
        return;
    }
    ProcessRulebook(PROCEDURAL_RB, 0, true);
];
[ EndFollowRulebook r x y;
    if (rulechange_stack-->rulechange_sp == RS_SUCCEEDS) r = 1;
    else if (rulechange_stack-->rulechange_sp == RS_FAILS) r = 0;
    else r = -1;
    if (r ~= -1) {
        x = rulechange_stack-->(rulechange_sp+1);
        y = rulechange_stack-->(rulechange_sp+2);
    }
    rule_frames--;
    while (rulechange_sp > 0) {
        rulechange_sp = rulechange_sp - 3;
        if (rulechange_stack-->rulechange_sp == RS_FRAME) break;
    }
    if (rulechange_sp == 0) rule_frames = 0;
    if (r == 1) rulechange_stack-->rulechange_sp = RS_SUCCEEDS;
    else if (r == 0) rulechange_stack-->rulechange_sp = RS_FAILS;
    if (r ~= -1) {
        rulechange_stack-->(rulechange_sp+1) = x;
        rulechange_stack-->(rulechange_sp+2) = y;
    }
];
```

§**4. Processing.** The routine `ProcessRulebook` is arguably the most important in the whole of I7. It does something essentially simple but has deceptively complicated implications. To complicate matters, it reuses its variables to keep the virtual machine stack usage to an absolute minimum – here we use 10 locals per call to `ProcessRulebook`, which is the fewest I can comfortably manage. In the early days of I7, stack usage became a serious issue since some forms of the Frotz Z-machine interpreter provided only 4K of stack by default. ("Only" 4K. In the mid-1980s, one of the obstacles facing IF authors at Infocom was the need to get the stack usage down to fewer than 600 bytes in order that the story file could be run on the smaller home computers of the day.)

`ProcessRulebook` takes three arguments, of which only the first is compulsory:

(a) The `rulebook` is an I7 value of kind "rule", which means it can be either the ID number of a rulebook – from 0 up to $N-1$, where N is the number of rulebooks compiled by NI, typically about 600 – or else the address of a routine representing an individual rule.

(b) The `parameter` supplied to the rulebook. Much as arguments can be supplied to a function in a conventional language's function call, so a parameter can be supplied whenever a rulebook is invoked.

(c) The value `bits` is initially a flag: if not supplied, this is `false`; if explicitly set `true`, then the rulebook is run with paragraph breaking suppressed. This is the process by which paragraph division points are placed between rules, so that if two rules both print text then a paragraph break appears between. While that is appropriate for rulebooks attached to actions or for "every turn" rules, it is disastrous for rulebooks attached to activities such as "printing the name of something". Once the routine is running, however, `bits` becomes a bitmap containing five flags, made up from the `RS_*_BIT` values defined below.

`ProcessRulebook` returns `true` if the rulebook or rule chose to "succeed" or "fail", and `false` if it made no choice. (To repeat: if the rule explicitly fails, then `ProcessRulebook` returns `true`. It's easy to write plausible-looking code which goes wrong because it assumes that the return value is success vs. failure.) The outcome of `ProcessRulebook` is lodged just above the top of this stack: thus the most recent rule or rulebook succeeded or failed if –

```
    (rulechange_stack-->rulechange_sp == RS_SUCCEEDS)
    (rulechange_stack-->rulechange_sp == RS_FAILS)
```

and otherwise there was no decision. If there was indeed a decision, then the second word of this record is a flag: `true` means that a value was returned, in which case the third word is that value, and `false` means that no value was returned, so that the third word is meaningless.

```
Constant RS_ACTIVE_BIT = 1;
Constant RS_MOVED_BIT = 2;
Constant RS_USERESULT_BIT = 4;
Constant RS_ACTIVITY = 8;
Constant RS_NOSKIPS = 16;
Constant RS_AFFECTED_BIT = 32;

    rulechange_stack-->rulechange_sp = 0;
    debugging_rules = usage;
    rfalse;
];
```

§**5. Specifying Outcomes.** The following provide ways for rules to succeed, fail or decline to do either.

`SetRulebookOutcome` is a little different: it changes the outcome state of the most recent rule completed, not the current one. (It's used only when saving and restoring this in the actions machinery: rules should not call it.)

```
[ ActRulebookSucceeds rule_id;
    if (rule_id) reason_the_action_failed = rule_id;
    RulebookSucceeds();
];
[ ActRulebookFails rule_id;
    if (rule_id) reason_the_action_failed = rule_id;
    RulebookFails();
];
[ RulebookSucceeds valueflag value;
    PushRuleChange(RS_SUCCEEDS, valueflag, value);
    rulechange_sp = rulechange_sp - 3;
];
[ RulebookFails valueflag value;
    PushRuleChange(RS_FAILS, valueflag, value);
    rulechange_sp = rulechange_sp - 3;
];
[ RuleHasNoOutcome;
    PushRuleChange(RS_NEITHER, 0, 0);
    rulechange_sp = rulechange_sp - 3;
];
```

```
[ SetRulebookOutcome a;
    rulechange_stack-->rulechange_sp = a;
];
```

§**6. Discovering Outcomes.** And here is how to tell what the results were.

```
[ RulebookOutcome a;
    a = rulechange_stack-->rulechange_sp;
    if ((a == RS_FAILS) || (a == RS_SUCCEEDS)) return a;
    return RS_NEITHER;
];
[ RulebookFailed;
    if (rulechange_stack-->rulechange_sp == RS_FAILS) rtrue; rfalse;
];
[ RulebookSucceeded;
    if (rulechange_stack-->rulechange_sp == RS_SUCCEEDS) rtrue; rfalse;
];
[ ResultOfRule a;
    a = rulechange_stack-->rulechange_sp;
    if ((a == RS_FAILS) || (a == RS_SUCCEEDS)) {
        a = rulechange_stack-->(rulechange_sp + 1);
        if (a) return rulechange_stack-->(rulechange_sp + 2);
    }
    return 0;
];
```

§**7. Procedural Rule Changes.** The following routines provide a sort of rule-changing API, and correspond closely to the I7 phrases documented in *Writing with Inform*, so they won't be discussed in any detail here.

```
Global DITS_said = false;
[ SuppressRule rule;
    if (rule == TURN_SEQUENCE_RB) {
        if (DITS_said == false) RunTimeProblem(RTP_DONTIGNORETURNSEQUENCE);
        DITS_said = true;
    } else PushRuleChange(RS_DONOTRUN, rule, 0);
];
[ ReinstateRule rule; PushRuleChange(RS_RUN, rule, 0); ];
[ DonotuseRule rule; PushRuleChange(RS_DONOTUSE, rule, 0); ];
[ UseRule rule; PushRuleChange(RS_USE, rule, 0); ];
[ SubstituteRule rule1 rule2; PushRuleChange(RS_SUBSTITUTE, rule2, rule1); ];
[ MoveRuleBefore rule1 rule2; PushRuleChange(RS_MOVEBEFORE, rule1, rule2); ];
[ MoveRuleAfter rule1 rule2; PushRuleChange(RS_MOVEAFTER, rule1, rule2); ];
```

§**8. Printing Rule Names.** This is the I6 printing rule used for a value of kind "rule", which as noted above can either be rulebook ID numbers in the range 0 to $N-1$ or are addresses of individual rules.

Names of rules and rulebooks take up a fair amount of space, and one of the main memory economies enforced by the "Use memory economy" option is to omit the necessary arrays. (It's not the text which is the problem so much as the table of addresses pointing to that text, which has to live in precious readable memory on the Z-machine.)

```
#IFNDEF MEMORY_ECONOMY;
{-array:RulebookNames}
#ENDIF; ! MEMORY_ECONOMY
[ RulePrintingRule R p1;
#ifndef MEMORY_ECONOMY;
    if ((R>=0) && (R<NUMBER_RULEBOOKS_CREATED)) {
        print (string) (RulebookNames-->R);
    } else {
{-call:compile_rule_printing_switch}
        print "(nameless rule at address ", R, ")";
    }
#ifnot;
    if ((R>=0) && (R<NUMBER_RULEBOOKS_CREATED)) {
        print "(rulebook ", R, ")";
    } else {
        print "(rule at address ", R, ")";
    }
#endif;
];
```

§**9. Debugging.** Two modest routines to print out the names of rules and rulebooks when they occur, in so far as memory economy allows this.

```
[ DebugRulebooks subs parameter i;
    spaces(2*process_rulebook_count);
    print "[", (RulePrintingRule) subs;
    if (parameter) print " / on O", parameter;
    print "]^";
];
[ DB_Rule R N blocked;
    if (R==0) return;
    print "[Rule ~", (RulePrintingRule) R, "~ ";
    #ifdef NUMBERED_RULES; print "(", N, ") "; #endif;
    if (blocked == false) "applies.]";
    "does not apply.]";
];
```

Parser Template B/parst

Purpose

The parser for turning the text of the typed command into a proposed action by the player.

---

§**1. Grammar Line Variables.** This is the I6 library parser in mostly untouched form: reformatted for template file use, and with paragraph divisions, but otherwise hardly changed at all. It is a complex algorithm but one which is known to produce good results for the most part, and it is well understood from (at time of writing) fifteen years of use. A few I7 additions have been made, but none disrupting the basic method. For instance, I7's system for resolving ambiguities is implemented by providing a `ChooseObjects` routine, just as a user of the I6 library would do.

The I6 parser uses a huge number of global variables, which is not to modern programming tastes: in the early days of Inform, the parser was essentially written in assembly-language only lightly structured by C-like syntaxes, and the Z-machine's 240 globals were more or less registers. The I6 library made no distinction between which were "private" to the parser and which allowed to be accessed by the user's code at large. The I7 template does impose that boundary, though not very strongly: the variables defined in "Output.i6t" are for general access, while the ones below should only be read or written by the parser.

```
Global best_etype;                  ! Preferred error number so far
Global nextbest_etype;              ! Preferred one, if ASKSCOPE_PE disallowed
Global parser_inflection;           ! A property (usually "name") to find object names in
Array pattern --> 32;               ! For the current pattern match
Global pcount;                      ! and a marker within it
Array pattern2 --> 32;              ! And another, which stores the best match
Global pcount2;                     ! so far
Array  line_ttype-->32;             ! For storing an analysed grammar line
Array  line_tdata-->32;
Array  line_token-->32;
Global nsns;                        ! Number of special_numbers entered so far
Global params_wanted;               ! Number of parameters needed (which may change in parsing)
Global inferfrom;                   ! The point from which the rest of the command must be inferred
Global inferword;                   ! And the preposition inferred
Global dont_infer;                  ! Another dull flag
Global cobj_flag = 0;
Global oops_from;                   ! The "first mistake" word number
Global saved_oops;                  ! Used in working this out
Array  oops_workspace -> 64;        ! Used temporarily by "oops" routine
```

```
Global held_back_mode;              ! Flag: is there some input from last time
Global hb_wn;                       ! left over?  (And a save value for wn.)
                                      ! (Used for full stops and "then".)
Global usual_grammar_after;         ! Point from which usual grammar is parsed (it may vary from
                                      ! the above if user's routines match multi-word verbs)
```

§**2. Grammar Token Variables.** More globals, but dealing at the level of individual tokens now.

```
Constant PATTERN_NULL = $ffff;      ! Entry for a token producing no text
Global found_ttype;                 ! Used to break up tokens into type
Global found_tdata;                 ! and data (by AnalyseToken)
Global token_filter;                ! For noun filtering by user routines
Global length_of_noun;              ! Set by NounDomain to no of words in noun
Global lookahead;                   ! The token after the one now being matched
Global multi_mode;                  ! Multiple mode
Global multi_wanted;                ! Number of things needed in multitude
Global multi_had;                   ! Number of things actually found
Global multi_context;               ! What token the multi-obj was accepted for
Global indef_mode;                  ! "Indefinite" mode - ie, "take a brick"
                                      ! is in this mode
Global indef_type;                  ! Bit-map holding types of specification
Global indef_wanted;                ! Number of items wanted (INDEF_ALL_WANTED for all)
Constant INDEF_ALL_WANTED = 32767;
Global indef_guess_p;               ! Plural-guessing flag
Global indef_owner;                 ! Object which must hold these items
Global indef_cases;                 ! Possible gender and numbers of them
Global indef_possambig;             ! Has a possibly dangerous assumption
                                      ! been made about meaning of a descriptor?
Global indef_nspec_at;              ! Word at which a number like "two" was parsed
                                      ! (for backtracking)
Global allow_plurals;               ! Whether plurals presently allowed or not
Global take_all_rule;               ! Slightly different rules apply to "take all" than other uses
                                      ! of multiple objects, to make adjudication produce more
                                      ! pragmatically useful results
                                      ! (Not a flag: possible values 0, 1, 2)
Global dict_flags_of_noun;          ! Of the noun currently being parsed
                                      ! (a bitmap in #dict_par1 format)
Global pronoun__word;               ! Saved value
Global pronoun__obj;                ! Saved value
Constant comma_word = 'comma,';     ! An "untypeable word" used to substitute
                                      ! for commas in parse buffers
```

§**3. Match List Variables.** The most difficult tokens to match are those which refer to objects, since there is such a variety of names which can be given to any individual object, and we don't of course know which object or objects are meant. We store the possibilities (up to `MATCH_LIST_WORDS`, anyway) in a data structure called the match list.

```
Array  match_list --> MATCH_LIST_WORDS;    ! An array of matched objects so far
Array  match_classes --> MATCH_LIST_WORDS; ! An array of equivalence classes for them
Array  match_scores --> MATCH_LIST_WORDS;  ! An array of match scores for them
Global number_matched;              ! How many items in it?  (0 means none)
Global number_of_classes;           ! How many equivalence classes?
Global match_length;                ! How many words long are these matches?
Global match_from;                  ! At what word of the input do they begin?
```

§**4. Words.** The player's command is broken down into a numbered sequence of words, which break at spaces or certain punctuation (see the DM4). The numbering runs upwards from 1 to `WordCount()`. The following utility routines provide access to words in the current command; because buffers have different definitions in Z and Glulx, so these routines must vary also.

The actual text of each word is stored as a sequence of ZSCII values in a `->` (byte) array, with address `WordAddress(x)` and length `WordLength(x)`.

We picture the command as a stream of words to be read one at a time, with the global variable `wn` being the "current word" marker. `NextWord`, which takes no arguments, returns:

(a) 0 if the word at `wn` is unrecognised by the dictionary or `wn` is out of range,
(b) `comma_word` if the word was a comma,
(c) `THEN1__WD` if it was a full stop (because of the Infocom tradition that a full stop abbreviates for the word "then": e.g., TAKE BOX. EAST was read as two commands in succession),
(d) or the dictionary address if the word was recognised.

The current word marker `wn` is always advanced.

`NextWordStopped` does the same, but returns −1 when `wn` is out of range (e.g., by having advanced past the last word in the command).

`MoveWord(at1, b2, at2)` copies word `at2` from parse buffer `b2` – which doesn't need to be `buffer` – to word `at1` in `parse`.

```
#Ifdef TARGET_ZCODE;
[ WordCount; return parse->1; ];
[ WordAddress wordnum; return buffer + parse->(wordnum*4+1); ];
[ WordLength wordnum; return parse->(wordnum*4); ];
[ MoveWord at1 b2 at2 x y;
    x = at1*2-1; y = at2*2-1;
    parse-->x++ = b2-->y++;
    parse-->x = b2-->y;
];
#Ifnot;
[ WordCount; return parse-->0; ];
[ WordAddress wordnum; return buffer + parse-->(wordnum*3); ];
[ WordLength wordnum; return parse-->(wordnum*3-1); ];
[ MoveWord at1 b2 at2 x y;
    x = at1*3-2; y = at2*3-2;
    parse-->x++ = b2-->y++;
    parse-->x++ = b2-->y++;
    parse-->x = b2-->y;
];
#Endif;
```

```
[ NextWord i j wc;
    #Ifdef TARGET_ZCODE; wc = parse->1; i = wn*2-1;
    #Ifnot; wc = parse-->0; i = wn*3-2; #Endif;
    wn++;
    if ((wn < 2) || (wn > wc+1)) return 0;
    j = parse-->i;
    if (j == ',//') j = comma_word;
    if (j == './/') j = THEN1__WD;
    return j;
];
[ NextWordStopped wc;
    #Ifdef TARGET_ZCODE; wc = parse->1; #Ifnot; wc = parse-->0; #Endif;
    if ((wn < 1) || (wn > wc)) { wn++; return -1; }
    return NextWord();
];
```

§**5. Snippets.** Although the idea is arguably implicit in I6, the formal concept of "snippet" is new in I7. A snippet is a value which represents a word range in the command most recently typed by the player. These words number consecutively upwards from 1, as noted above. The correspondence between (w_1, w_2), the word range, and V, the number used to represent it as an I6 value, is:

$$V = 100w_1 + (w_2 - w_1 + 1)$$

so that the remainder mod 100 is the number of words in the range. We require that $1 \leq w_1 \leq w_2 \leq N$, where N is the number of words in the current player's command. The entire command is therefore represented by:

$$C = 100 + N$$

```
[ PrintSnippet snip from to i w1 w2;
    w1 = snip/100; w2 = w1 + (snip%100) - 1;
    if ((w2<w1) || (w1<1) || (w2>WordCount()))
        return RunTimeProblem(RTP_SAYINVALIDSNIPPET, w1, w2);
    from = WordAddress(w1); to = WordAddress(w2) + WordLength(w2) - 1;
    for (i=from: i<=to: i++) print (char) i->0;
];
[ SpliceSnippet snip t i w1 w2 nextw at endsnippet newlen;
    w1 = snip/100; w2 = w1 + (snip%100) - 1;
    if ((w2<w1) || (w1<1) || (w2>WordCount()))
        return RunTimeProblem(RTP_SPLICEINVALIDSNIPPET, w1, w2);
    @push say__p; @push say__pc;
    nextw = w2 + 1;
    at = WordAddress(w1) - buffer;
    if (nextw <= WordCount()) endsnippet = 100*nextw + (WordCount() - nextw + 1);
    buffer2-->0 = 120;
    newlen = VM_PrintToBuffer(buffer2, 120, SpliceSnippet__TextPrinter, t, endsnippet);
    for (i=0: (i<newlen) && (at+i<120): i++) buffer->(at+i) = buffer2->(WORDSIZE+i);
    #Ifdef TARGET_ZCODE; buffer->1 = at+i; #ifnot; buffer-->0 = at+i; #endif;
    for (:at+i<120:i++) buffer->(at+i) = ' ';
    VM_Tokenise(buffer, parse);
    players_command = 100 + WordCount();
    @pull say__pc; @pull say__p;
];
```

```
[ SpliceSnippet__TextPrinter t endsnippet;
    PrintText(t);
    if (endsnippet) { print " "; PrintSnippet(endsnippet); }
];
[ SnippetIncludes test snippet w1 w2 wlen i j;
    w1 = snippet/100; w2 = w1 + (snippet%100) - 1;
    if ((w2<w1) || (w1<1))
        return RunTimeProblem(RTP_INCLUDEINVALIDSNIPPET, w1, w2);
    if (metaclass(test) == Routine) {
        wlen = snippet%100;
        for (i=w1, j=wlen: j>0: i++, j--) {
            if (((test)(i, 0)) ~= GPR_FAIL) return i*100+wn-i;
        }
    }
    rfalse;
];
[ SnippetMatches snippet topic_gpr rv;
    wn=1;
    if (topic_gpr == 0) rfalse;
    if (metaclass(topic_gpr) == Routine) {
        rv = (topic_gpr)(snippet/100, snippet%100);
        if (rv ~= GPR_FAIL) rtrue;
        rfalse;
    }
    RunTimeProblem(RTP_BADTOPIC);
    rfalse;
];
```

§**6. Unpacking Grammar Lines.** Grammar lines are sequences of tokens in an array built into the story file, but in a format which differs depending on the virtual machine in use, so the following code unpacks the data into more convenient if larger arrays which are VM-independent.

```
[ UnpackGrammarLine line_address i size;
    for (i=0 : i<32 : i++) {
        line_token-->i = ENDIT_TOKEN;
        line_ttype-->i = ELEMENTARY_TT;
        line_tdata-->i = ENDIT_TOKEN;
    }
#Ifdef TARGET_ZCODE;
    action_to_be = 256*(line_address->0) + line_address->1;
    action_reversed = ((action_to_be & $400) ~= 0);
    action_to_be = action_to_be & $3ff;
    line_address--;
    size = 3;
#Ifnot; ! GLULX
    @aloads line_address 0 action_to_be;
    action_reversed = (((line_address->2) & 1) ~= 0);
    line_address = line_address - 2;
    size = 5;
#Endif;
    params_wanted = 0;
    for (i=0 : : i++) {
```

```
        line_address = line_address + size;
        if (line_address->0 == ENDIT_TOKEN) break;
        line_token-->i = line_address;
        AnalyseToken(line_address);
        if (found_ttype ~= PREPOSITION_TT) params_wanted++;
        line_ttype-->i = found_ttype;
        line_tdata-->i = found_tdata;
    }
    return line_address + 1;
];
[ AnalyseToken token;
    if (token == ENDIT_TOKEN) {
        found_ttype = ELEMENTARY_TT;
        found_tdata = ENDIT_TOKEN;
        return;
    }
    found_ttype = (token->0) & $$1111;
    found_tdata = (token+1)-->0;
];
```

§**7. Extracting Verb Numbers.** A long tale of woe lies behind the following. Infocom games stored verb numbers in a single byte in dictionary entries, but they did so counting downwards, so that verb number 0 was stored as 255, 1 as 254, and so on. Inform followed suit so that debugging of Inform 1 could be aided by using the then-available tools for dumping dictionaries from Infocom story files; by using the Infocom format for dictionary tables, Inform's life was easier.

But there was an implicit restriction there of 255 distinct verbs (not 256 since not all words were verbs). When Glulx raised almost all of the Z-machine limits, it made space for 65535 verbs instead of 255, but it appears that nobody remembered to implement this in I6-for-Glulx and the Glulx form of the I6 library. This was only put right in March 2009, and the following routine was added to concentrate lookups of this field in one place.

```
[ DictionaryWordToVerbNum dword verbnum;
#Ifdef TARGET_ZCODE;
    verbnum = $ff-(dword->#dict_par2);
#Ifnot; ! GLULX
    dword = dword + #dict_par2 - 1;
    @aloads dword 0 verbnum;
    verbnum = $ffff-verbnum;
#Endif;
    return verbnum;
];
```

§**8. Keyboard Primitive.** This is the primitive routine to read from the keyboard: it usually delegates this to a routine specific to the virtual machine being used, but sometimes uses a hacked version to allow TEST commands to work. (When a TEST is running, the text in the walk-through provided is fed into the buffer as if it had been typed at the keyboard.)

```
[ KeyboardPrimitive a_buffer a_table;
#Ifdef DEBUG; #Iftrue ({-value:NUMBER_CREATED(test_scenario)} > 0);
    return TestKeyboardPrimitive(a_buffer, a_table);
#Endif; #Endif;
    return VM_ReadKeyboard(a_buffer, a_table);
];
```

§**9. Reading the Command.** The `Keyboard` routine actually receives the player's words, putting the words in `a_buffer` and their dictionary addresses in `a_table`. It is assumed that the table is the same one on each (standard) call. Much of the code handles the OOPS and UNDO commands, which are not actions and do not pass through the rest of the parser. The undo state is saved – it is essentially an internal saved game, in the VM interpreter's memory rather than in an external file – and note that this is therefore also where execution picks up if an UNDO has been typed. Since UNDO recreates the former machine state perfectly, it might seem impossible to tell that an UNDO had occurred, but in fact the VM passes information back in the form of a return code from the relevant instruction, and this allows us to detect an undo. (We deal with it by printing the current location and asking another command.)

`Keyboard` can also be used by miscellaneous routines in the game to ask yes/no questions and the like, without invoking the rest of the parser.

The return value is the number of words typed.

```
[ Keyboard  a_buffer a_table  nw i w w2 x1 x2;
    sline1 = score; sline2 = turns;
    while (true) {
        ! Save the start of the buffer, in case "oops" needs to restore it
        for (i=0 : i<64 : i++) oops_workspace->i = a_buffer->i;
        ! In case of an array entry corruption that shouldn't happen, but would be
        ! disastrous if it did:
        #Ifdef TARGET_ZCODE;
        a_buffer->0 = INPUT_BUFFER_LEN;
        a_table->0 = 15;  ! Allow to split input into this many words
        #Endif; ! TARGET_
        ! Print the prompt, and read in the words and dictionary addresses
        PrintPrompt();
        DrawStatusLine();
        KeyboardPrimitive(a_buffer, a_table);
        ! Set nw to the number of words
        #Ifdef TARGET_ZCODE; nw = a_table->1; #Ifnot; nw = a_table-->0; #Endif;
        ! If the line was blank, get a fresh line
        if (nw == 0) {
            @push etype; etype = BLANKLINE_PE;
            players_command = 100;
            BeginActivity(PRINTING_A_PARSER_ERROR_ACT);
            if (ForActivity(PRINTING_A_PARSER_ERROR_ACT) == false) L__M(##Miscellany,10);
            EndActivity(PRINTING_A_PARSER_ERROR_ACT);
            @pull etype;
            continue;
```

```
}
! Unless the opening word was OOPS, return
! Conveniently, a_table-->1 is the first word on both the Z-machine and Glulx
w = a_table-->1;
if (w == OOPS1__WD or OOPS2__WD or OOPS3__WD) {
    if (oops_from == 0) { L__M(##Miscellany, 14); continue; }
    if (nw == 1) { L__M(##Miscellany, 15); continue; }
    if (nw > 2) { L__M(##Miscellany, 16); continue; }
    ! So now we know: there was a previous mistake, and the player has
    ! attempted to correct a single word of it.
    for (i=0 : i<INPUT_BUFFER_LEN : i++) buffer2->i = a_buffer->i;
    #Ifdef TARGET_ZCODE;
    x1 = a_table->9;  ! Start of word following "oops"
    x2 = a_table->8;  ! Length of word following "oops"
    #Ifnot; ! TARGET_GLULX
    x1 = a_table-->6; ! Start of word following "oops"
    x2 = a_table-->5; ! Length of word following "oops"
    #Endif; ! TARGET_
    ! Repair the buffer to the text that was in it before the "oops"
    ! was typed:
    for (i=0 : i<64 : i++) a_buffer->i = oops_workspace->i;
    VM_Tokenise(a_buffer,a_table);
    ! Work out the position in the buffer of the word to be corrected:
    #Ifdef TARGET_ZCODE;
    w = a_table->(4*oops_from + 1); ! Start of word to go
    w2 = a_table->(4*oops_from);    ! Length of word to go
    #Ifnot; ! TARGET_GLULX
    w = a_table-->(3*oops_from);      ! Start of word to go
    w2 = a_table-->(3*oops_from - 1); ! Length of word to go
    #Endif; ! TARGET_
    ! Write spaces over the word to be corrected:
    for (i=0 : i<w2 : i++) a_buffer->(i+w) = ' ';
    if (w2 < x2) {
        ! If the replacement is longer than the original, move up...
        for (i=INPUT_BUFFER_LEN-1 : i>=w+x2 : i--)
            a_buffer->i = a_buffer->(i-x2+w2);
        ! ...increasing buffer size accordingly.
        #Ifdef TARGET_ZCODE;
        a_buffer->1 = (a_buffer->1) + (x2-w2);
        #Ifnot; ! TARGET_GLULX
        a_buffer-->0 = (a_buffer-->0) + (x2-w2);
        #Endif; ! TARGET_
    }
    ! Write the correction in:
    for (i=0 : i<x2 : i++) a_buffer->(i+w) = buffer2->(i+x1);
    VM_Tokenise(a_buffer, a_table);
    #Ifdef TARGET_ZCODE; nw = a_table->1; #Ifnot; nw = a_table-->0; #Endif;
    return nw;
}
! Undo handling
```

```
        if ((w == UNDO1__WD or UNDO2__WD or UNDO3__WD) && (nw==1)) {
            Perform_Undo();
            continue;
        }
        i = VM_Save_Undo();
        #ifdef PREVENT_UNDO; undo_flag = 0; #endif;
        #ifndef PREVENT_UNDO; undo_flag = 2; #endif;
        if (i == -1) undo_flag = 0;
        if (i == 0) undo_flag = 1;
        if (i == 2) {
            VM_RestoreWindowColours();
            VM_Style(SUBHEADER_VMSTY);
            SL_Location(); print "^";
            ! print (name) location, "^";
            VM_Style(NORMAL_VMSTY);
            L__M(##Miscellany, 13);
            continue;
        }
        return nw;
    }
];
```

§**10. Parser Proper.** The main parser routine is something of a leviathan, and it has traditionally been divided into 11 lettered parts:

(A) Get the input, do OOPS and AGAIN
(B) Is it a direction, and so an implicit GO? If so go to (K)
(C) Is anyone being addressed?
(D) Get the command verb: try all the syntax lines for that verb
(E) Break down a syntax line into analysed tokens
(F) Look ahead for advance warning for `multiexcept`/`multiinside`
(G) Parse each token in turn (calling `ParseToken` to do most of the work)
(H) Cheaply parse otherwise unrecognised conversation and return
(I) Print best possible error message
(J) Retry the whole lot
(K) Last thing: check for THEN and further instructions(s), return.

This lettering has been preserved here, with the code under each letter now being the body of "Parser Letter A", "Parser Letter B" and so on.

Note that there are three different places where a return can happen. The routine returns only when a sensible request has been made; for a fairly thorough description of its output, which is written into the `results` array but also into several globals, see "OrderOfPlay.i6t".

```
[ Parser__parse results
    syntax line num_lines line_address i j k token l m;

    cobj_flag = 0;
    results-->0 = 0; results-->1 = 0; results-->2 = 0; results-->3 = 0;
    meta = false;
```

§**11. Parser Letter A.** Get the input, do OOPS and AGAIN.

```
    if (held_back_mode == 1) {
        held_back_mode = 0;
        VM_Tokenise(buffer, parse);
        jump ReParse;
    }

§**18. Parser Letter H.** Cheaply parse otherwise unrecognised conversation and return.

(Errors are handled differently depending on who was talking. If the command was addressed to somebody else (eg, DWARF, SFGH) then it is taken as conversation which the parser has no business in disallowing.)

The parser used to return the fake action `##NotUnderstood` when a command in the form PERSON, ARFLE BARFLE GLOOP is parsed, where a character is addressed but with an instruction which the parser can't understand. (If a command such as ARFLE BARFLE GLOOP is not an instruction to someone else, the parser prints an error and requires the player to type another command: thus `##NotUnderstood` was only returned when `actor` is not the player.) And I6 had elaborate object-oriented ways to deal with this, but we won't use any of that: we simply convert to a `##Answer` action, which communicates a snippet of words to another character, just as if the player had typed ANSWER ARFLE BARFLE GLOOP TO PERSON. For I7 purposes, the fake action `##NotUnderstood` does not exist.

```

```

§**22. End of Parser Proper.**

```
]; ! end of Parser__parse
```

§**23. Parse Token.** The main parsing routine above tried a sequence of "grammar lines" in turn, matching each against the text typed until one fitted. A grammar line is itself a sequence of "grammar tokens". Here we have to parse the tokens.

`ParseToken(type, data)` tries the match text beginning at the current word marker `wn` against a token of the given `type`, with the given `data`. The optional further arguments `token_n` and `token` supply the token number in the current grammar line (because some tokens do depend on what has happened before or is needed later) and the address of the dictionary word which makes up the `token`, in the case where it's a "preposition".

The return values are:
(a) `GPR_REPARSE` for "I have rewritten the command, please re-parse from scratch";
(b) `GPR_PREPOSITION` for "token accepted with no result";
(c) $-256 + x$ for "please parse `ParseToken(ELEMENTARY_TT, x)` instead";
(d) 0 for "token accepted, result is the multiple object list";
(e) 1 for "token accepted, result is the number in parsed$_n umber''$";
(f) an object number for "token accepted with this object as result";
(g) -1 for "token rejected".

Strictly speaking `ParseToken` is a shell routine which saves the current state on the stack, and calling `ParseToken__` to do the actual work.

Once again the routine is traditionally divided into six letters, here named under paragraphs "Parse Token Letter A", and so on.

(A) Analyse the token; handle all tokens not involving object lists and break down others into elementary tokens
(B) Begin parsing an object list
(C) Parse descriptors (articles, pronouns, etc.) in the list
(D) Parse an object name
(E) Parse connectives (AND, BUT, etc.) and go back to (C)
(F) Return the conclusion of parsing an object list

```

]; ! end of ParseToken__
```

§**30. Descriptors.** In grammatical terms, a descriptor appears at the front of an English noun phrase and clarifies the quantity or specific identity of what is referred to: for instance, *my* mirror, *the* dwarf, *that* woman. (Numbers, as in *four* duets, are also descriptors in linguistics: but the I6 parser doesn't handle them that way.)

Slightly unfortunately, the bitmap constants used for descriptors in the I6 parser have names in the form `*_BIT`, coinciding with the names of style bits in the list-writer: but they never occur in the same context.

The actual words used as descriptors are read from tables in the language definition. `ArticleDescriptors` uses this table to move current word marker past a run of one or more descriptors which refer to the definite or indefinite article.

```
Constant OTHER_BIT  =   1;     !  These will be used in Adjudicate()
Constant MY_BIT     =   2;     !  to disambiguate choices
Constant THAT_BIT   =   4;
Constant PLURAL_BIT =   8;
Constant LIT_BIT    =  16;
Constant UNLIT_BIT  =  32;

[ ResetDescriptors;
    indef_mode = 0; indef_type = 0; indef_wanted = 0; indef_guess_p = 0;
    indef_possambig = false;
    indef_owner = nothing;
    indef_cases = $$111111111111;
    indef_nspec_at = 0;
];

[ ArticleDescriptors  o x flag cto type n;
    if (wn > num_words) return 0;
    for (flag=true : flag :) {
        o = NextWordStopped(); flag = false;
    for (x=1 : x<=LanguageDescriptors-->0 : x=x+4)
            if (o == LanguageDescriptors-->x) {
                type = LanguageDescriptors-->(x+2);
                if (type == DEFART_PK or INDEFART_PK) flag = true;
            }
    }
    wn--;
    return 0;
];
```

§**31. Parsing Descriptors.** The `Descriptors()` routine parses the descriptors at the head of a noun phrase, leaving the current word marker `wn` at the first word of the noun phrase's body. It is allowed to set up for a plural only if `allow_p` is set; it returns a parser error number, or 0 if no error occurred.

```
[ Descriptors  o x flag cto type n;
    ResetDescriptors();
    if (wn > num_words) return 0;
    for (flag=true : flag :) {
        o = NextWordStopped(); flag = false;

§**32. Preposition Chain.** A small utility for runs of prepositions.

```
[ PrepositionChain wd index;
    if (line_tdata-->index == wd) return wd;
    if ((line_token-->index)->0 & $20 == 0) return -1;
    do {
        if (line_tdata-->index == wd) return wd;
        index++;
    } until ((line_token-->index == ENDIT_TOKEN) || (((line_token-->index)->0 & $10) == 0));
    return -1;
];
```

§**33. Creature.** Will this object do for an I6 `creature` token? (In I7 terms, this affects the tokens "[someone]", "[somebody]", "[anyone]" and "[anybody]".)

```
[ CreatureTest obj;
    if (obj has animate) rtrue;
    if (obj hasnt talkable) rfalse;
    if (action_to_be == ##Ask or ##Answer or ##Tell or ##AskFor) rtrue;
    rfalse;
];
```

§**34. Noun Domain.** `NounDomain` does the most substantial part of parsing an object name. It is given two "domains" – usually a location and then the actor who is looking – and a context (i.e. token type), and returns:

(a) 0 if no match at all could be made,
(b) 1 if a multiple object was made,
(c) k if object k was the one decided upon,
(d) `REPARSE_CODE` if it asked a question of the player and consequently rewrote the player's input, so that the whole parser should start again on the rewritten input.

In case (c), `NounDomain` also sets the variable `length_of_noun` to the number of words in the input text matched to the noun. In case (b), the multiple objects are added to `multiple_object` by hand (not by `MultiAdd`, because we want to allow duplicates).

```
[ NounDomain domain1 domain2 context
    first_word i j k l answer_words marker;
    #Ifdef DEBUG;
    if (parser_trace >= 4) {
        print "   [NounDomain called at word ", wn, "^";

§**35. Adjudicate.** The `Adjudicate` routine tries to see if there is an obvious choice, when faced with a list of objects (the `match_list`) each of which matches the player's specification equally well. To do this it makes use of the `context` (the token type being worked on).

It counts up the number of obvious choices for the given context – all to do with where a candidate is, except for 6 (`animate`) which is to do with whether it is animate or not – and then:

(a) if only one obvious choice is found, that is returned;
(b) if we are in indefinite mode (don't care which) one of the obvious choices is returned, or if there is no obvious choice then an unobvious one is made;
(c) at this stage, we work out whether the objects are distinguishable from each other or not: if they are all indistinguishable from each other, then choose one, it doesn't matter which;
(d) otherwise, 0 (meaning, unable to decide) is returned (but remember that the equivalence classes we've just worked out will be needed by other routines to clear up this mess, so we can't economise on working them out).

`Adjudicate` returns -1 if an error occurred.

```

§**37. Match List.** The match list is an array, `match_list-->`, which holds the current best guesses at what object(s) a portion of the command refers to. The global `number_matched` is set to the current length of the `match_list`.

When the parser sees a possible match of object `obj` at quality level `q`, it calls `MakeMatch(obj, q)`. If this is the best quality match so far, then we wipe out all the previous matches and start a new list with this one. If it's only as good as the best so far, we add it to the list (provided we haven't run out of space, and provided it isn't in the list already). If it's worse, we ignore it altogether.

I6 tokens in the form `noun=Filter` or `Attribute` are "noun filter tokens", and mean that the match list should be filtered to accept only nouns which are acceptable to the given routine, or have the given attribute. Such a token is in force if `token_filter` is used. (I7 makes no use of this in the attribute case, which is deprecated nowadays.)

Quality is essentially the number of words in the command referring to the object: the idea is that "red panic button" is better than "red button" or "panic".

```
[ MakeMatch obj quality i;
    #Ifdef DEBUG;
    if (parser_trace >= 6) print "    Match with quality ",quality,"^";
    #Endif; ! DEBUG
    if (token_filter ~= 0 && ConsultNounFilterToken(obj) == 0) {
        #Ifdef DEBUG;
        if (parser_trace >= 6) print "    Match filtered out: token filter ", token_filter, "^";
        #Endif; ! DEBUG
        rtrue;
    }
    if (quality < match_length) rtrue;
    if (quality > match_length) { match_length = quality; number_matched = 0; }
    else {
        if (number_matched >= MATCH_LIST_WORDS) rtrue;
        for (i=0 : i<number_matched : i++)
            if (match_list-->i == obj) rtrue;
    }
    match_list-->number_matched++ = obj;
    #Ifdef DEBUG;
    if (parser_trace >= 6) print "    Match added to list^";
    #Endif; ! DEBUG
];
[ ConsultNounFilterToken obj;
    if (token_filter ofclass Routine) {
        noun = obj;
        return indirect(token_filter);
    }
    if (obj has (token_filter-1)) rtrue;
    rfalse;
];
```

§**38. ScoreMatchL.** `ScoreMatchL` scores the match list for quality in terms of what the player has vaguely asked for. Points are awarded for conforming with requirements like "my", and so on. Remove from the match list any entries which fail the basic requirements of the descriptors. (The scoring system used to evaluate the possibilities is discussed in detail in the DM4.)

            }
            number_matched--;
        }
    }
];
```

§**39. BestGuess.** `BestGuess` makes the best guess it can out of the match list, assuming that everything in the match list is textually as good as everything else; however it ignores items marked as −1, and so marks anything it chooses. It returns −1 if there are no possible choices.

```
[ BestGuess  earliest its_score best i;
    earliest = 0; best = -1;
    for (i=0 : i<number_matched : i++) {
        if (match_list-->i >= 0) {
            its_score = match_scores-->i;
            if (its_score > best) { best = its_score; earliest = i; }
        }
    }
    #Ifdef DEBUG;
    if (parser_trace >= 4)
    if (best < 0) print "   Best guess ran out of choices^";
    else print "   Best guess ", (the) match_list-->earliest,
        " (", match_list-->earliest, ")^";
    #Endif; ! DEBUG
    if (best < 0) return -1;
    i = match_list-->earliest;
    match_list-->earliest = -1;
    return i;
];
```

§**40. SingleBestGuess.** `SingleBestGuess` returns the highest-scoring object in the match list if it is the clear winner, or returns −1 if there is no clear winner.

```
[ SingleBestGuess  earliest its_score best i;
    earliest = -1; best = -1000;
    for (i=0 : i<number_matched : i++) {
        its_score = match_scores-->i;
        if (its_score == best) earliest = -1;
        if (its_score > best) { best = its_score; earliest = match_list-->i; }
    }
    return earliest;
];
```

§**41. Identical.** `Identical` decides whether or not two objects can be distinguished from each other by anything the player can type. If not, it returns `true`. (This routine is critical to the handling of plurals, and the list-writer requires it to be an equivalence relation between objects: but it is, because it is equivalent to $O_1 \sim O_2$ if and only if $f(O_1) = f(O_2)$ for some function f.)

```
[ Identical o1 o2 p1 p2 n1 n2 i j flag;
    if (o1 == o2) rtrue;  ! This should never happen, but to be on the safe side
    if (o1 == 0 || o2 == 0) rfalse;  ! Similarly
    if (o1 ofclass K3_direction || o2 ofclass K3_direction) rfalse; ! Saves time
    !  What complicates things is that o1 or o2 might have a parsing routine,
    !  so the parser can't know from here whether they are or aren't the same.
    !  If they have different parsing routines, we simply assume they're
    !  different.  If they have the same routine (which they probably got from
    !  a class definition) then the decision process is as follows:
    !
    !     the routine is called (with self being o1, not that it matters)
    !       with noun and second being set to o1 and o2, and action being set
    !       to the fake action TheSame.  If it returns -1, they are found
    !       identical; if -2, different; and if >=0, then the usual method
    !       is used instead.
    if (o1.parse_name ~= 0 || o2.parse_name ~= 0) {
    if (o1.parse_name ~= o2.parse_name) rfalse;
    parser_action = ##TheSame; parser_one = o1; parser_two = o2;
    j = wn; i = RunRoutines(o1,parse_name); wn = j;
    if (i == -1) rtrue;
    if (i == -2) rfalse;
    }
    !  This is the default algorithm: do they have the same words in their
    !  "name" (i.e. property no. 1) properties.  (Note that the following allows
    !  for repeated words and words in different orders.)
    p1 = o1.&1; n1 = (o1.#1)/WORDSIZE;
    p2 = o2.&1; n2 = (o2.#1)/WORDSIZE;
    !  for (i=0 : i<n1 : i++) { print (address) p1-->i, " "; } new_line;
    !  for (i=0 : i<n2 : i++) { print (address) p2-->i, " "; } new_line;
    for (i=0 : i<n1 : i++) {
        flag = 0;
        for (j=0 : j<n2 : j++)
            if (p1-->i == p2-->j) flag = 1;
        if (flag == 0) rfalse;
    }
    for (j=0 : j<n2 : j++) {
        flag = 0;
        for (i=0 : i<n1 : i++)
            if (p1-->i == p2-->j) flag = 1;
        if (flag == 0) rfalse;
    }
    !  print "Which are identical!^";
    rtrue;
];
```

§**42. Print Command.** `PrintCommand` reconstructs the command as it presently reads, from the pattern which has been built up.

If `from` is 0, it starts with the verb: then it goes through the pattern.

The other parameter is `emptyf` – a flag: if 0, it goes up to `pcount`: if 1, it goes up to `pcount`-1.

Note that verbs and prepositions are printed out of the dictionary: and that since the dictionary may only preserve the first six characters of a word (in a V3 game), we have to hand-code the longer words needed. At present, I7 doesn't do this, but it probably should.

(Recall that pattern entries are 0 for "multiple object", 1 for "special word", 2 to `REPARSE_CODE-1` are object numbers and `REPARSE_CODE+n` means the preposition `n`.)

```
[ PrintInferredCommand from singleton_noun;
    singleton_noun = FALSE;
    if ((from ~= 0) && (from == pcount-1) &&
        (pattern-->from > 1) && (pattern-->from < REPARSE_CODE))
            singleton_noun = TRUE;
    if (singleton_noun) {
        BeginActivity(CLARIFYING_PARSERS_CHOICE_ACT, pattern-->from);
        if (ForActivity(CLARIFYING_PARSERS_CHOICE_ACT, pattern-->from) == 0) {
            print "("; PrintCommand(from); print ")^";
        }
        EndActivity(CLARIFYING_PARSERS_CHOICE_ACT, pattern-->from);
    } else {
        print "("; PrintCommand(from); print ")^";
    }
];
[ PrintCommand from i k spacing_flag;
    if (from == 0) {
        i = verb_word;
        if (LanguageVerb(i) == 0)
            if (PrintVerb(i) == 0) print (address) i;
        from++; spacing_flag = true;
    }
    for (k=from : k<pcount : k++) {
        i = pattern-->k;
        if (i == PATTERN_NULL) continue;
        if (spacing_flag) print (char) ' ';
        if (i == 0) { print (string) THOSET__TX; jump TokenPrinted; }
        if (i == 1) { print (string) THAT__TX;   jump TokenPrinted; }
        if (i >= REPARSE_CODE)
            print (address) VM_NumberToDictionaryAddress(i-REPARSE_CODE);
        else
            if (i ofclass K3_direction)
                print (LanguageDirection) i; ! the direction name as adverb
            else
                print (the) i;
    .TokenPrinted;
        spacing_flag = true;
    }
];
```

§**43. CantSee.** The `CantSee` routine returns a good error number for the situation where the last word looked at didn't seem to refer to any object in context.

The idea is that: if the actor is in a location (but not inside something like, for instance, a tank which is in that location) then an attempt to refer to one of the words listed as meaningful-but-irrelevant there will cause "you don't need to refer to that in this game" rather than "no such thing" or "what's 'it'?".

(The advantage of not having looked at "irrelevant" local nouns until now is that it stops them from clogging up the ambiguity-resolving process. Thus game objects always triumph over scenery.)

```
[ CantSee  i w e;
    saved_oops=oops_from;
    if (scope_token ~= 0) {
        scope_error = scope_token; return ASKSCOPE_PE;
    }
    wn--; w = NextWord();
    e = CANTSEE_PE;
    if (w == pronoun_word) {
        pronoun__word = pronoun_word; pronoun__obj = pronoun_obj;
        e = ITGONE_PE;
    }
    if (etype > e) return etype;
    return e;
];
```

§**44. Multiple Object List.** The `MultiAdd` routine adds object `o` to the multiple-object-list. This is only allowed to hold `MATCH_LIST_WORDS` minus one objects at most, at which point it ignores any new entries (and sets a global flag so that a warning may later be printed if need be).

The `MultiSub` routine deletes object `o` from the multiple-object-list. It returns 0 if the object was there in the first place, and 9 (because this is the appropriate error number in `Parser()`) if it wasn't.

The `MultiFilter` routine goes through the multiple-object-list and throws out anything without the given attribute `attr` set.

```
[ MultiAdd o i j;
    i = multiple_object-->0;
    if (i == MATCH_LIST_WORDS-1) { toomany_flag = 1; rtrue; }
    for (j=1 : j<=i : j++)
        if (o == multiple_object-->j) rtrue;
    i++;
    multiple_object-->i = o;
    multiple_object-->0 = i;
];
[ MultiSub o i j k;
    i = multiple_object-->0;
    for (j=1 : j<=i : j++)
        if (o == multiple_object-->j) {
            for (k=j : k<=i : k++) multiple_object-->k = multiple_object-->(k+1);
            multiple_object-->0 = --i;
            return 0;
        }
    return VAGUE_PE;
];
[ MultiFilter attr  i j o;
```

```
    .MFiltl;
    i = multiple_object-->0;
    for (j=1 : j<=i : j++) {
        o = multiple_object-->j;
        if (o hasnt attr) { MultiSub(o); jump Mfiltl; }
    }
];
```

§**45. Scope.** The scope of an actor is the set of objects which he can refer to in typed commands, which is normally the same as the set of visible objects; but this can be modified. This is how I7 handles tokens like "[any room]".

Scope determination is done by calling `SearchScope` to iterate through the objects in scope, and "visit" each one: which means, carry out some task for each as we get there. The task depends on the current value of `scope_reason`, which is `PARSING_REASON` when the parser is matching command text against object names.

The scope machinery is built on a number of levels, each making use only of lower levels:

(0) Either `NounDomain`, `TestScope` or `LoopOverScope` makes one or more calls to `SearchScope` (on level 1). The point of making multiple calls is to influence the order in which items in scope are visited, which improves the quality of "take all"-style multiple object lists, for instance.

(1) `SearchScope` searches for the objects in scope which are within first one domain, and then another: for instance, first within the current room but not within the current actor, and then within the current actor. It can be called either from level 0, or externally from the choose-objects machinery, but is not recursive. It works within the context of a given token in the parser (when called for `PARSING_REASON`) and in particular the `multiinside` token, and also handles testing commands, scope tokens, scope in darkness, and intervention by the I7 "deciding the scope of" activity. Most of its actual searches are delegated to `ScopeWithin` (level 2), but it also uses `DoScopeActionAndRecurse` (level 3) and `DoScopeAction` (level 4) as necessary.

(2) `ScopeWithin` iterates through the objects in scope which are within one supplied domain, but not within another. It can be called either from level 1, or independently from rules in the "deciding the scope of" activity via the I7 "place the contents of X in scope" phrase. It calls `DoScopeActionAndRecurse` (level 3) on any unconcealed objects it finds.

(3) `DoScopeActionAndRecurse` visits a given object by calling down to `DoScopeAction` (level 4), and recurses to all unconcealed object-tree contents and component parts of the object. The I7 phrase "place X in scope" uses this routine.

(4) `DoScopeAction` simply visits a single object, taking whatever action is needed there – which will depend on the `scope_reason`. The only use made by the parser of `TryGivenObject`, which tries to match command text against the name of a given object, is from here. The I7 phrase "place X in scope, but not its contents" uses this routine.

Two routines are provided for code external to the parser to modify the scope. They should be called only during scope deliberations – i.e., in `scope=...` tokens or in rules for the "deciding the scope of" activity. (At present, `AddToScope` is not used in I7 at all.) Note that this I7 form of `PlaceInScope` has a slightly different specification to its I6 library counterpart of the same name: it can place a room in scope. (In I6, room names were not normally parsed.)

```
[ PlaceInScope O opts; ! If opts is set, do not place contents in scope
    wn = match_from;
    if (opts == false) DoScopeActionAndRecurse(O);
    else DoScopeAction(O);
    return;
];
[ AddToScope obj;
    if (ats_flag >= 2) DoScopeActionAndRecurse(obj, 0, ats_flag-2);
    if (ats_flag == 1) { if (HasLightSource(obj)==1) ats_hls = 1; }
```

```
];
```

§**46. Scope Level 0.** The two ways of starting up the scope machinery other than via the parser code above.

```
[ TestScope obj act a al sr x y;
    x = parser_one; y = parser_two;
    parser_one = obj; parser_two = 0; a = actor; al = actors_location;
    sr = scope_reason; scope_reason = TESTSCOPE_REASON;
    if (act == 0) actor = player; else actor = act;
    actors_location = ScopeCeiling(actor);
    SearchScope(actors_location, actor, 0); scope_reason = sr; actor = a;
    actors_location = al; parser_one = x; x = parser_two; parser_two = y;
    return x;
];
[ LoopOverScope routine act x y a al;
    x = parser_one; y = scope_reason; a = actor; al = actors_location;
    parser_one = routine;
    if (act == 0) actor = player; else actor = act;
    actors_location = ScopeCeiling(actor);
    scope_reason = LOOPOVERSCOPE_REASON;
    SearchScope(actors_location, actor, 0);
    parser_one = x; scope_reason = y; actor = a; actors_location = al;
];
```

§**47. SearchScope.** Level 1. The method is:

(a) If the context is a `scope=...` token, then the search is delegated to "stage 2" of the scope routine. This was the old I6 way to override the searching behaviour: while users probably won't be using it any more, the template does, in order to give testing commands universal scope which is exempt from the activity below; and the NI compiler creates `scope=...` tokens to handle Understand grammar such as "[any room]". So the feature remains very much still in use.

(b) The "deciding the scope of" activity is given the chance to intervene. This is the I7 way to override the searching behaviour, and is the one taken by users.

(c) And otherwise:

(1) The I6 `multiinside` token, used as the first noun of its grammar line, has as its scope all of the objects which are inside or on top of the *second* noun of the grammar line. This provides a neat scope for the ALL in a command like GET ALL FROM CUPBOARD, where the player clearly does not intend ALL to refer to the cupboard itself, for instance. The difficulty is that we don't yet know what the second object is, if we are parsing left to right. But the parser code above has taken care of all of that, and the `advance_warning` global is set to the object number of the second noun, or to -1 if that is not yet known. Note that we check that the contents are visible before adding them to scope, because otherwise an unscrupulous player could use such a command to detect the contents of an opaque locked box. If this rule applies, we skip (c.2), (c.3) and (c.4).

(2) For all other tokens except `creature`, searching scope for the room holding the current actor always catches the compass directions unless a definite article has already been typed. (Thus OPEN THE EAST would match an object called "east door", but not the compass direction "east".)

(3) The contents of `domain1` which are not contents of `domain2` are placed in scope, and so are any component parts of `domain1`. If `domain1` is a container or supporter, it is placed in scope itself.

(4) The contents and component parts of `domain2` are placed in scope. If `domain2` is a container or supporter, it is placed in scope itself.

(5) In darkness, the actor and his component parts are in scope. If the actor is inside or on top of something, then that thing is also in scope. (This avoids a situation where the player gets into an

opaque box, then pulls it closed from the inside, plunging himself into darkness, then types OPEN BOX only to be told that he can't see any such thing.)

```
[ SearchScope domain1 domain2 context i;
    if (domain1 == 0) return;
    ! (a)
    if (scope_token) {
        scope_stage = 2;
        #Ifdef DEBUG;
        if (parser_trace >= 3) print "  [Scope routine called at stage 2]^";
        #Endif;
        if (indirect(scope_token) ~= 0) rtrue;
    }
    ! (b)
    BeginActivity(DECIDING_SCOPE_ACT, actor);
    if (ForActivity(DECIDING_SCOPE_ACT, actor) == false) {
        ! (c.1)
        if ((scope_reason == PARSING_REASON) && (context == MULTIINSIDE_TOKEN) &&
            (advance_warning ~= -1)) {
            if (IsSeeThrough(advance_warning) == 1)
                ScopeWithin(advance_warning, 0, context);
        } else {
            ! (c.2)
            if ((scope_reason == PARSING_REASON) && (context ~= CREATURE_TOKEN) &&
                (indef_mode == 0) && (domain1 == actors_location))
                    ScopeWithin(compass);
            ! (c.3)
            if (domain1 has supporter or container) DoScopeAction(domain1);
            ScopeWithin(domain1, domain2, context);
            ! (c.4)
            if (domain2) {
                if (domain2 has supporter or container) DoScopeAction(domain2);
                ScopeWithin(domain2, 0, context);
            }
        }
        ! (c.5)
        if (thedark == domain1 or domain2) {
            DoScopeActionAndRecurse(actor, actor, context);
            if (parent(actor) has supporter or container)
                DoScopeActionAndRecurse(parent(actor), parent(actor), context);
        }
    }
    EndActivity(DECIDING_SCOPE_ACT, actor);
];
```

§**48. ScopeWithin.** Level 2. `ScopeWithin` puts objects visible from within the `domain` into scope. An item belonging to the `domain` is placed in scope unless it is being concealed by the `domain`: and even then, if the `domain` is the current actor. Suppose Zorro conceals a book beneath his cloak: then the book is not in scope to his lady friend The Black Whip, but it is in scope to Zorro himself. (Thus an actor is not allowed to conceal anything from himself.)

Note that the `domain` object itself, and its component parts if any, are not placed in scope by this routine, though nothing prevents some other code doing so.

```
[ ScopeWithin domain nosearch context obj next_obj;
    if (domain == 0) rtrue;
    ! Look through the objects in the domain, avoiding "objectloop" in case
    ! movements occur.
    obj = child(domain);
    while (obj) {
        next_obj = sibling(obj);
        if ((domain == actor) || (TestConcealment(domain, obj) == false))
            DoScopeActionAndRecurse(obj, nosearch, context);
        obj = next_obj;
    }
];
```

§**49. DoScopeActionAndRecurse.** Level 3. In all cases, the `domain` itself is visited. There are then three possible forms of recursion:

(a) To unconcealed objects which are inside, on top of, carried or worn by the `domain`: this is called "searching" in traditional I6 language and is suppressed if `domain` is the special value `nosearch`.
(b) To unconcealed component parts of the `domain`.
(c) To any other objects listed in the `add_to_scope` property array, or supplied by the `add_to_scope` property routine, if it has one. (I7 does not usually use `add_to_scope`, but it remains a useful hook in the parser, so it retains its old I6 library interpretation.)

```
[ DoScopeActionAndRecurse domain nosearch context i ad n obj next_obj;
    DoScopeAction(domain);
    ! (a)
    if ((domain ~= nosearch) &&
        ((domain ofclass K1_room or K8_person) || (IsSeeThrough(domain) == 1))) {
        obj = child(domain);
        while (obj) {
            next_obj = sibling(obj);
            if ((domain == actor) || (TestConcealment(domain, obj) == false))
                DoScopeActionAndRecurse(obj, nosearch, context);
            obj = next_obj;
        }
    }
    ! (b)
    if (domain provides component_child) {
        obj = domain.component_child;
        while (obj) {
            next_obj = obj.component_sibling;
            if ((domain == actor) || (TestConcealment(domain, obj) == false))
                DoScopeActionAndRecurse(obj, 0, context);
            obj = next_obj;
        }
```

```
    }
    ! (c)
    ad = domain.&add_to_scope;
    if (ad ~= 0) {
        ! Test if the property value is not an object.
        #Ifdef TARGET_ZCODE;
        i = (UnsignedCompare(ad-->0, top_object) > 0);
        #Ifnot; ! TARGET_GLULX
        i = (((ad-->0)->0) ~= $70);
        #Endif; ! TARGET_
        if (i) {
            ats_flag = 2+context;
            RunRoutines(domain, add_to_scope);
            ats_flag = 0;
        }
        else {
            n = domain.#add_to_scope;
            for (i=0 : (WORDSIZE*i)<n : i++)
                if (ad-->i)
                    DoScopeActionAndRecurse(ad-->i, 0, context);
        }
    }
];
```

§**50. DoScopeAction.** Level 4. This is where we take whatever action is to be performed as the "visit" to each scoped object, and it's the bottom at last of the scope mechanism.

```
[ DoScopeAction item;
    #Ifdef DEBUG;
    if (parser_trace >= 6)
        print "[DSA on ", (the) item, " with reason = ", scope_reason,
            " p1 = ", parser_one, " p2 = ", parser_two, "]^";
    #Endif; ! DEBUG
    @push parser_one; @push scope_reason;
    switch(scope_reason) {
        TESTSCOPE_REASON: if (item == parser_one) parser_two = 1;
        LOOPOVERSCOPE_REASON: if (parser_one ofclass Routine) indirect(parser_one, item);
        PARSING_REASON, TALKING_REASON: MatchTextAgainstObject(item);
    }
    @pull scope_reason; @pull parser_one;
];
```

§**51. Parsing Object Names.** We now reach the final major block of code in the parser: the part which tries to match a given object's name(s) against the text at word position `match_from` in the player's command, and calls `MakeMatch` if it succeeds. There are basically four possibilities: ME, a pronoun such as IT, a name which doesn't begin misleadingly with a number, and a name which does. In the latter two cases, we pass the job down to `TryGivenObject`.

```
[ MatchTextAgainstObject item i;
    if (match_from <= num_words) { ! If there's any text to match, that is
        wn = match_from;
        i = NounWord();
        if ((i == 1) && (player == item)) MakeMatch(item, 1); ! "me"
        if ((i >= 2) && (i < 128) && (LanguagePronouns-->i == item)) MakeMatch(item, 1);
    }

    ! Construing the current word as the start of a noun, can it refer to the
    ! object?

    wn = match_from;
    if (TryGivenObject(item) > 0)
        if (indef_nspec_at > 0 && match_from ~= indef_nspec_at) {
            ! This case arises if the player has typed a number in
            ! which is hypothetically an indefinite descriptor:
            ! e.g. "take two clubs".  We have just checked the object
            ! against the word "clubs", in the hope of eventually finding
            ! two such objects.  But we also backtrack and check it
            ! against the words "two clubs", in case it turns out to
            ! be the 2 of Clubs from a pack of cards, say.  If it does
            ! match against "two clubs", we tear up our original
            ! assumption about the meaning of "two" and lapse back into
            ! definite mode.

            wn = indef_nspec_at;
            if (TryGivenObject(item) > 0) {
                match_from = indef_nspec_at;
                ResetDescriptors();
            }
            wn = match_from;
        }
];
```

§**52. TryGivenObject.** `TryGivenObject` tries to match as many words as possible in what has been typed to the given object, `obj`. If it manages any words matched at all, it calls `MakeMatch` to say so, then returns the number of words (or 1 if it was a match because of inadequate input).

```
[ TryGivenObject obj nomatch threshold k w j;
    #Ifdef DEBUG;
    if (parser_trace >= 5) print "    Trying ", (the) obj, " (", obj, ") at word ", wn, "^";
    #Endif; ! DEBUG
    if (nomatch && obj == 0) return 0;
! if (nomatch) print "*** TryGivenObject *** on ", (the) obj, " at wn = ", wn, "^";
    dict_flags_of_noun = 0;
!  If input has run out then always match, with only quality 0 (this saves
!  time).
    if (wn > num_words) {
        if (nomatch) return 0;
        if (indef_mode ~= 0)
            dict_flags_of_noun = $$01110000;  ! Reject "plural" bit
        MakeMatch(obj,0);
        #Ifdef DEBUG;
        if (parser_trace >= 5) print "    Matched (0)^";
        #Endif; ! DEBUG
        return 1;
    }
!  Ask the object to parse itself if necessary, sitting up and taking notice
!  if it says the plural was used:
    if (obj.parse_name~=0) {
        parser_action = NULL; j=wn;
        k = RunRoutines(obj,parse_name);
        if (k > 0) {
            wn=j+k;
        .MMbyPN;
            if (parser_action == ##PluralFound)
                dict_flags_of_noun = dict_flags_of_noun | 4;
            if (dict_flags_of_noun & 4) {
                if (~~allow_plurals) k = 0;
                else {
                    if (indef_mode == 0) {
                        indef_mode = 1; indef_type = 0; indef_wanted = 0;
                    }
                    indef_type = indef_type | PLURAL_BIT;
                    if (indef_wanted == 0) indef_wanted = INDEF_ALL_WANTED;
                }
            }
            #Ifdef DEBUG;
            if (parser_trace >= 5) print "    Matched (", k, ")^";
            #Endif; ! DEBUG
            if (nomatch == false) MakeMatch(obj,k);
            return k;
        }
        if (k == 0) jump NoWordsMatch;
    }
```

```
    ! The default algorithm is simply to count up how many words pass the
    ! Refers test:
    parser_action = NULL;
    w = NounWord();
    if (w == 1 && player == obj) { k=1; jump MMbyPN; }
    if (w >= 2 && w < 128 && (LanguagePronouns-->w == obj)) { k = 1; jump MMbyPN; }
    if (Refers(obj, wn-1) == 0) {
        .NoWordsMatch;
        if (indef_mode ~= 0) { k = 0; parser_action = NULL; jump MMbyPN; }
        rfalse;
    }
    threshold = 1;
    dict_flags_of_noun = (w->#dict_par1) & $$01110100;
    w = NextWord();
    while (Refers(obj, wn-1)) {
        threshold++;
        if (w)
        dict_flags_of_noun = dict_flags_of_noun | ((w->#dict_par1) & $$01110100);
        w = NextWord();
    }
    k = threshold;
    jump MMbyPN;
];
```

§**53. Refers.** `Refers` works out whether the word at number wnum can refer to the object `obj`, returning true or false. The standard method is to see if the word is listed under the `name` property for the object, but this is more complex in languages other than English.

```
[ Refers obj wnum   wd k l m;
    if (obj == 0) rfalse;
    #Ifdef LanguageRefers;
    k = LanguageRefers(obj,wnum); if (k >= 0) return k;
    #Endif; ! LanguageRefers
    k = wn; wn = wnum; wd = NextWordStopped(); wn = k;
    if (parser_inflection >= 256) {
        k = indirect(parser_inflection, obj, wd);
        if (k >= 0) return k;
        m = -k;
    }
    else
        m = parser_inflection;
    k = obj.&m; l = (obj.#m)/WORDSIZE-1;
    for (m=0 : m<=l : m++)
        if (wd == k-->m) rtrue;
    rfalse;
];
[ WordInProperty wd obj prop k l m;
    k = obj.&prop; l = (obj.#prop)/WORDSIZE-1;
    for (m=0 : m<=l : m++)
        if (wd == k-->m) rtrue;
```

```
    rfalse;
];
```

§**54. NounWord.** `NounWord` (which takes no arguments) returns:
(a) 0 if the next word is not in the dictionary or is but does not carry the "noun" bit in its dictionary entry,
(b) 1 if it is a word meaning "me",
(c) the index in the pronoun table (plus 2) of the value field of a pronoun, if it is a pronoun,
(d) the address in the dictionary if it is a recognised noun.

```
[ NounWord i j s;
    i = NextWord();
    if (i == 0) rfalse;
    if (i == ME1__WD or ME2__WD or ME3__WD) return 1;
    s = LanguagePronouns-->0;
    for (j=1 : j<=s : j=j+3)
        if (i == LanguagePronouns-->j)
            return j+2;
    if ((i->#dict_par1)&128 == 0) rfalse;
    return i;
];
```

§**55. TryNumber.** `TryNumber` takes word number `wordnum` and tries to parse it as an (unsigned) decimal number or the name of a small number, returning

(a) −1000 if it is not a number
(b) the number, if it has between 1 and 4 digits
(c) 10000 if it has 5 or more digits.

(The danger of allowing 5 digits is that Z-machine integers are only 16 bits long, and anyway this routine isn't meant to be perfect: it only really needs to be good enough to handle numeric descriptors such as those in TAKE 31 COINS or DROP FOUR DAGGERS. In particular, it is not the way I7 "[number]" tokens are parsed.)

```
[ TryNumber wordnum   i j c num len mul tot d digit;
    i = wn; wn = wordnum; j = NextWord(); wn = i;
    j = NumberWord(j); ! Test for verbal forms ONE to TWENTY
    if (j >= 1) return j;
    #Ifdef TARGET_ZCODE;
    i = wordnum*4+1; j = parse->i; num = j+buffer; len = parse->(i-1);
    #Ifnot; ! TARGET_GLULX
    i = wordnum*3; j = parse-->i; num = j+buffer; len = parse-->(i-1);
    #Endif; ! TARGET_
    if (len >= 4) mul=1000;
    if (len == 3) mul=100;
    if (len == 2) mul=10;
    if (len == 1) mul=1;
    tot = 0; c = 0; len = len-1;
    for (c=0 : c<=len : c++) {
        digit=num->c;
        if (digit == '0') { d = 0; jump digok; }
        if (digit == '1') { d = 1; jump digok; }
        if (digit == '2') { d = 2; jump digok; }
        if (digit == '3') { d = 3; jump digok; }
```

```
        if (digit == '4') { d = 4; jump digok; }
        if (digit == '5') { d = 5; jump digok; }
        if (digit == '6') { d = 6; jump digok; }
        if (digit == '7') { d = 7; jump digok; }
        if (digit == '8') { d = 8; jump digok; }
        if (digit == '9') { d = 9; jump digok; }
        return -1000;
    .digok;
        tot = tot+mul*d; mul = mul/10;
    }
    if (len > 3) tot=10000;
    return tot;
];
```

§**56. Extended TryNumber.** The same, but recognising verbal forms up to 30.

```
[ I7_ExtendedTryNumber wordnum i j;
    i = wn; wn = wordnum; j = NextWordStopped(); wn = i;
    switch (j) {
        'twenty-one': return 21;
        'twenty-two': return 22;
        'twenty-three': return 23;
        'twenty-four': return 24;
        'twenty-five': return 25;
        'twenty-six': return 26;
        'twenty-seven': return 27;
        'twenty-eight': return 28;
        'twenty-nine': return 29;
        'thirty': return 30;
        default: return TryNumber(wordnum);
    }
];
```

§**57. Gender.** `GetGender` returns 0 if the given animate object is female, and 1 if male, and is abstracted as a routine in case something more elaborate is ever needed.

For GNAs – gender/noun/animation combinations – see the *Inform Designer's Manual*, 4th edition.

```
[ GetGender person;
    if (person hasnt female) rtrue;
    rfalse;
];
[ GetGNAOfObject obj case gender;
    if (obj hasnt animate) case = 6;
    if (obj has male) gender = male;
    if (obj has female) gender = female;
    if (obj has neuter) gender = neuter;
    if (gender == 0) {
        if (case == 0) gender = LanguageAnimateGender;
        else gender = LanguageInanimateGender;
    }
    if (gender == female)   case = case + 1;
    if (gender == neuter)   case = case + 2;
```

```
    if (obj has pluralname) case = case + 3;
    return case;
];
```

§58. Noticing Plurals.

```
[ DetectPluralWord at n i w swn outcome;
    swn = wn; wn = at;
    for (i=0:i<n:i++) {
        w = NextWordStopped();
        if (w == 0 or THEN1__WD or COMMA_WORD or -1) break;
        if ((w->#dict_par1) & $$00000100) {
            parser_action = ##PluralFound;
            outcome = true;
        }
    }
    wn = swn;
    return outcome;
];
```

§59. Pronoun Handling.

```
[ SetPronoun dword value x;
    for (x=1 : x<=LanguagePronouns-->0 : x=x+3)
        if (LanguagePronouns-->x == dword) {
            LanguagePronouns-->(x+2) = value; return;
        }
    RunTimeError(14);
];
[ PronounValue dword x;
    for (x=1 : x<=LanguagePronouns-->0 : x=x+3)
        if (LanguagePronouns-->x == dword)
            return LanguagePronouns-->(x+2);
    return 0;
];
[ ResetVagueWords obj; PronounNotice(obj); ];
[ PronounNotice obj x bm;
    if (obj == player) return;
    bm = PowersOfTwo_TB-->(GetGNAOfObject(obj));
    for (x=1 : x<=LanguagePronouns-->0 : x=x+3)
        if (bm & (LanguagePronouns-->(x+1)) ~= 0)
            LanguagePronouns-->(x+2) = obj;
];
[ PronounNoticeHeldObjects x;
#IFNDEF MANUAL_PRONOUNS;
    objectloop(x in player) PronounNotice(x);
#ENDIF;
    x = 0; ! To prevent a "not used" error
    rfalse;
];
```

§60. Yes/No Questions.

```
[ YesOrNo i j;
    for (::) {
        #Ifdef TARGET_ZCODE;
        if (location == nothing || parent(player) == nothing) read buffer parse;
        else read buffer parse DrawStatusLine;
        j = parse->1;
        #Ifnot; ! TARGET_GLULX;
        KeyboardPrimitive(buffer, parse);
        j = parse-->0;
        #Endif; ! TARGET_
        if (j) { ! at least one word entered
            i = parse-->1;
            if (i == YES1__WD or YES2__WD or YES3__WD) rtrue;
            if (i == NO1__WD or NO2__WD or NO3__WD) rfalse;
        }
        L__M(##Quit, 1); print "> ";
    }
];
```

§61. Number Words. Not much of a parsing routine: we look through an array of pairs of number words (single words) and their numeric equivalents.

```
[ NumberWord o i n;
    n = LanguageNumbers-->0;
    for (i=1 : i<=n : i=i+2)
        if (o == LanguageNumbers-->i) return LanguageNumbers-->(i+1);
    return 0;
];
```

§62. Choose Objects. This material, the final body of code in the parser, is an I7 addition. The I6 parser leaves it to the user to provide a `ChooseObjects` routine to decide between possibilities when the situation is ambiguous. For I7 use, we provide a `ChooseObjects` which essentially runs the "does the player mean" rulebook to decide, though this is not obvious from the code below because it is hidden in the `CheckDPMR` routine – which is defined in the Standard Rules, not here.

```
!Constant COBJ_DEBUG;

! the highest value returned by CheckDPMR (see the Standard Rules)
Constant HIGHEST_DPMR_SCORE = 4;

Array alt_match_list --> (MATCH_LIST_WORDS+1);

#ifdef TARGET_GLULX;
[ COBJ__Copy words from to  i;
    for (i=0: i<words: i++)
        to-->i = from-->i;
];
#ifnot;
[ COBJ__Copy words from to  bytes;
    bytes = words * 2;
    @copy_table from to bytes;
];
```

```
#endif;
! swap alt_match_list with match_list/number_matched
[ COBJ__SwapMatches i x;
    ! swap the counts
    x = number_matched;
    number_matched = alt_match_list-->0;
    alt_match_list-->0 = x;
    ! swap the values
    if (x < number_matched) x = number_matched;
    for (i=x: i>0: i--) {
        x = match_list-->(i-1);
        match_list-->(i-1) = alt_match_list-->i;
        alt_match_list-->i = x;
    }
];
[ ChooseObjects obj code  l i swn spcount;

ListWriter Template B/lwt

Purpose

A flexible object-lister taking care of plurals, inventory information, various formats and so on.

---

§**1. Specification.** The list-writer is called by one of the following function calls:

(1) `WriteListOfMarkedObjects(style)`, where the set of objects listed is understood to be exactly those with the `workflag2` attribute set, and
   (a) the `style` is a sum of `*_BIT` constants as defined in "Definitions.i6t".

(2) `WriteListFrom(obj, style, depth, noactivity, iterator)`, where only the first two parameters are compulsory:
   (a) the set of objects listed begins with `obj`;
   (b) the `style` is a sum of `*_BIT` constants as defined in "Definitions.i6t";
   (c) the `depth` is the recursion depth within the list – ordinarily 0, but by supplying a higher value, we can simulate a sublist of another list;
   (d) `noactivity` is a flag which forces the list-writer to ignore the "listing the contents of" activity (in cases where it would otherwise consult this): by default this is `false`;
   (e) `iterator` is an iterator function which provides the objects in sequence.

`WriteListOfMarkedObjects` is simply a front-end which supplies suitable parameters for `WriteListFrom`.

The iterator function is by default `ObjectTreeIterator`. This defines the sequence of objects as being the children of the parent of `obj`, in object tree sequence (that is: `child(parent(obj))` is first). Moreover, when using `ObjectTreeIterator`, the "listing the contents of" activity is carried out, unless `noactivity` is set.

We also provide the iterator function `MarkedListIterator`, which defines the sequence of objects as being the list in the word array `MarkedObjectArray` with length `MarkedObjectLength`. Here the "listing the contents of" activity is never used, since the objects are not necessarily the contents of any single thing. This of course is the iterator used by `WriteListOfMarkedObjects(style)`: it works by filling this array with all the objects having `workflag2` set.

The full specification for iterator functions is given below.

The list-writer automatically groups adjacent and indistinguishable terms in the sequence into plurals, and carries out the "printing the plural name" activity to handle these. Doing this alone would result in text such as "You can see a cake, three coins, an onion, and two coins here", where the five coins are mentioned in two clauses because they happen not to be adjacent in the list. The list-writer therefore carries out the activity "grouping together" to see if the user would like to tie certain objects together into a single entry: what this does is to set suitable `list_together` properties for the objects. NI has already given plural objects a similar `list_together` property. The net effect is that any entries in the list with a non-zero value of `list_together` must be adjacent to each other.

We could achieve that by sorting the list in order of `list_together` value, but that would result in drastic movements, whereas we want to upset the original ordering as little as possible. So instead we use a process called *coalescing* the list. This is such that for every value $L \neq 0$ of `list_together`, every entry with that value is moved back in the list to follow the first entry with that value. Thus if the original order is $x_1, x_2, ..., x_N$ then x_j still precedes x_k in coalesced order unless there exists $i < j < k$ such that $L(i) = L(k) \neq 0$ and $L(j) \neq L(i)$. This is as stable as it can be while achieving the "interval" property that non-zero L values occur in contiguous runs.

We therefore obtain text such as "You can see a cake, five coins, the tiles W, X, Y and Z from a Scrabble set, and an onion here." where the coins and the Scrabble tiles have been coalesced together in the list.

It's important to note that the default `ObjectTreeIterator` has the side-effect of actually reordering the object tree: it rearranges the children being listed so that they appear in the tree in coalesced order. The `MarkedListIterator` used by `WriteListOfMarkedObjects` has the same side-effect if the marked objects all happen to share a common parent. It might seem odd for a list-writer to have side effects at all, but the idea is that occasional coalescing improves the quality of play in many small ways – for instance, the sequence of matches to TAKE ALL is tidier – and that coalescing has a small speed cost, so we want to do it as little as possible. (The latter was more of a consideration for I6: interpreters are faster nowadays.)

This specification is somewhat stronger than that of the I6 library's traditional list-writer, because

(i) it supports arbitrary lists of objects, not just children of specific parents, while still allowing coalesced and grouped lists,
(ii) it can be used recursively in all cases,
(iii) it uses its own memory, rather than borrowing memory from the parser, so that it can safely be used while the parser is working, and
(iv) it manages this memory more flexibly and without silently failing by buffer overruns on unexpectedly large lists.

The I7 version of `WriteListFrom`, when using `ObjectTreeIterator`, differs from the I6 version in that the object `o` is required to be the `child` of its `parent`, that is, to be the eldest child. (So in effect it's a function of parents, not children, but we retain the form for familiarity's sake.) In practice this was invariably the way `WriteListFrom` was used even in I6 days.

Finally, the `ISARE_BIT` is differently interpreted in I7: instead of printing something like " are ducks and drakes", as it would have done in I6, the initial space is now suppressed and we instead print "are ducks and drakes".

§**2. Memory.** The list-writer needs to dynamically allocate temporary array space of a known size, in such a way that the array is effectively on the local stack frame: if only either the Z-machine or Glulx supported a stack in memory, this would be no problem, but they do not and we must therefore use the following.

The size of the stack is such that it can support a list which includes every object and recurses in turn to most other objects: in practice, this never happens. It would be nice to allocate more just in case, but the Z-machine is desperately short of array memory.

```
Constant REQUISITION_STACK_SIZE = 3*{-value:NUMBER_CREATED(world_object)};
Array requisition_stack --> REQUISITION_STACK_SIZE;
Global requisition_stack_pointer = 0;

[ RequisitionStack len top addr;
    top = requisition_stack_pointer + len;
    if (top > REQUISITION_STACK_SIZE) return false;
    addr = requisition_stack + requisition_stack_pointer*WORDSIZE;
    ! print "Allocating ", addr, " at pointer ", requisition_stack_pointer, "^";
    requisition_stack_pointer = top;
    return addr;
];

[ FreeStack addr;
    if (addr == 0) return;
    requisition_stack_pointer = (addr - requisition_stack)/WORDSIZE;
];
```

§**3. WriteListOfMarkedObjects.** This routine will use the `MarkedListIterator`. That means it has to create an array containing the object numbers of every object with the `workflag2` attribute set, placing the address of this array in `MarkedObjectArray` and the length in `MarkedObjectLength`. Note that we preserve any existing marked list on the stack (using the assembly-language instructions `@push` and `@pull`) for the duration of our use.

While the final order of this list will depend on what it looks like after coalescing, the initial order is also important. If all of the objects have a common parent in the object tree, then we coalesce those objects and place the list in object tree order. But if not, we place the list in object number order (which is essentially the order of traversal of the initial state of the object tree: thus objects in Room A will all appear before objects in Room B if A was created before B in the source text).

```
Global MarkedObjectArray = 0;
Global MarkedObjectLength = 0;

[ WriteListOfMarkedObjects style
    obj common_parent first mixed_parentage length;

    objectloop (obj ofclass Object && obj has workflag2) {
        length++;
        if (first == nothing) { first = obj; common_parent = parent(obj); }
        else { if (parent(obj) ~= common_parent) mixed_parentage = true; }
    }
    if (mixed_parentage) common_parent = nothing;

    if (length == 0) print (string) NOTHING__TX;
    else {

        @push MarkedObjectArray; @push MarkedObjectLength;
        MarkedObjectArray = RequisitionStack(length);
        MarkedObjectLength = length;
        if (MarkedObjectArray == 0) return RunTimeProblem(RTP_LISTWRITERMEMORY);

        if (common_parent) {
            ObjectTreeCoalesce(child(common_parent));
            length = 0;
            objectloop (obj in common_parent) ! object tree order
                if (obj has workflag2) MarkedObjectArray-->length++ = obj;
        } else {
            length = 0;
            objectloop (obj ofclass Object) ! object number order
                if (obj has workflag2) MarkedObjectArray-->length++ = obj;
        }

        WriteListFrom(first, style, 0, false, MarkedListIterator);

        FreeStack(MarkedObjectArray);
        @pull MarkedObjectLength; @pull MarkedObjectArray;
    }
    return;
];
```

§**4. About Iterator Functions.** Suppose `Iter` is an iterator function and that we have a "raw list" $x_1, x_2, ..., x_n$ of objects. Of these, the iterator function will choose a sublist of "qualifying" objects. It is called with arguments

```
Iter(obj, depth, L, function)
```

where the `obj` is required to be x_j for some j and the function is one of the `*_ITF` constants defined below:

(a) On `START_ITF`, we return x_1, or `nothing` if the list is empty.

(b) On `SEEK_ITF`, we return the smallest $k \geq j$ such that x_k qualifies, or `nothing` if none of $x_j, x_{j+1}, ..., x_n$ qualify.

(c) On `ADVANCE_ITF`, we return the smallest $k > j$ such that x_k qualifies, or `nothing` if none of $x_{j+1}, x_{j+2}..., x_n$ qualify.

(d) On `COALESCE_ITF`, we coalesce the entire list (not merely the qualifying entries) and return the new x_1, or `nothing` if the list is empty.

Thus, given any x_i, we can produce the sublist of qualifying entries by performing `START_ITF` on x_i, then `SEEK_ITF`, to produce q_1; then `ADVANCE_ITF` to produce q_2, and so on until `nothing` is returned, when there are no more qualifying entries. `SEEK_ITF` and `ADVANCE_ITF` always return qualifying objects, or `nothing`; but `START_ITF` and `COALESCE_ITF` may return a non-qualifying object, since there's no reason why x_1 should qualify in any ordering.

The iterator can make its own choice of which entries qualify, and of what the raw list is; `depth` is supplied to help in that decision. But if `L` is non-zero then the iterator is required to disqualify any entry whose `list_together` value is not `L`.

```
Constant SEEK_ITF = 0;
Constant ADVANCE_ITF = 1;
Constant COALESCE_ITF = 2;
Constant START_ITF = 3;
! Constant DBLW; ! Uncomment this to provide debugging information at run-time
```

§**5. Marked List Iterator.** Here the raw list is provided by the `MarkedObjectArray`, which is convenient for coalescing, but not so helpful for translating the `obj` parameter into the i such that it is x_i. We simply search from the beginning to do this, which combined with other code using the iterator makes for some unnecessary $O(n^2)$ calculations. But it saves memory and nuisance, and the iterator is used only with printing to the screen, which never needs to be very rapid anyway (because the player can only read very slowly).

```
[ MarkedListIterator obj depth required_lt function i;
    if (obj == nothing) return nothing;
    switch(function) {
        START_ITF: return MarkedObjectArray-->0;
        COALESCE_ITF: return MarkedListCoalesce();
        SEEK_ITF, ADVANCE_ITF:
            for (i=0: i<MarkedObjectLength: i++)
                if (MarkedObjectArray-->i == obj) {
                    if (function == ADVANCE_ITF) i++;
                    for (:i<MarkedObjectLength: i++) {
                        obj = MarkedObjectArray-->i;
                        if ((required_lt) && (obj.list_together ~= required_lt)) continue;
                        if ((c_style & WORKFLAG_BIT) && (depth==0) && (obj hasnt workflag))
                            continue;
                        if ((c_style & CONCEAL_BIT) &&
                            ((obj has concealed) || (obj has scenery))) continue;
                        return obj;
```

```
                    }
                    return nothing;
                }
    }
    return nothing;
];
```

§**6. Coalesce Marked List.** The return value is the new first entry in the raw list.

```
[ MarkedListCoalesce o i lt l swap m;
    for (i=0: i<MarkedObjectLength: i++) {
        lt = (MarkedObjectArray-->i).list_together;
        if (lt ~= 0) {
            ! Find first object in list after contiguous run with this list_together value:
            for (i++: (i<MarkedObjectLength)&&((MarkedObjectArray-->i).list_together==lt): i++) ;
            ! If the contiguous run extends to end of list, the list is now perfect:
            if (i == MarkedObjectLength) return MarkedObjectArray-->0;
            ! And otherwise we look to see if any future entries belong in the earlier run:
            for (l=i+1: l<MarkedObjectLength: l++)
                if ((MarkedObjectArray-->l).list_together == lt) {
                    ! Yes, they do: so we perform a rotation to insert it before element i:
                    swap = MarkedObjectArray-->l;
                    for (m=l: m>i: m--) MarkedObjectArray-->m = MarkedObjectArray-->(m-1);
                    MarkedObjectArray-->i = swap;
                    ! And now the run is longer:
                    i++;
                    if (i == MarkedObjectLength) return MarkedObjectArray-->0;
                }
            i--;
        }
    }
    return MarkedObjectArray-->0;
];
```

§**7. Object Tree Iterator.** Here the raw list is the list of all children of a given parent: since the argument `obj` is required to be a member of the raw list, we can use `parent(obj)` to find it. Now seeking and advancing are fast, but coalescing is slower.

```
Global list_filter_routine;

[ ObjectTreeIterator obj depth required_lt function;
    if ((obj == nothing) || (parent(obj) == nothing)) return nothing;
    if (function == START_ITF) return child(parent(obj));
    if (function == COALESCE_ITF) return ObjectTreeCoalesce(obj);
    if (function == ADVANCE_ITF) obj = sibling(obj);
    for (:: obj = sibling(obj)) {
        if (obj == nothing) return nothing;
        if ((required_lt) && (obj.list_together ~= required_lt)) continue;
        if ((c_style & WORKFLAG_BIT) && (depth==0) && (obj hasnt workflag)) continue;
        if (obj hasnt list_filter_permits) continue;
        if ((c_style & CONCEAL_BIT) &&
            ((obj has concealed) || (obj has scenery))) continue;
        return obj;
```

```
    }
];
```

§**8. Coalesce Object Tree.** Again, the return value is the new first entry in the raw list.

```
[ ObjectTreeCoalesce obj memb lt later;
    #Ifdef DBLW; print "^^Sorting out: "; DiagnoseSortList(obj); #Endif;
    .StartAgain;
    for (memb=obj: memb~=nothing: memb=sibling(memb)) {
        lt = memb.list_together;
        if (lt ~= 0) {
            ! Find first object in list after contiguous run with this list_together value:
            for (memb=sibling(memb): (memb) && (memb.list_together == lt): memb = sibling(memb)) ;
            ! If the contiguous run extends to end of list, the list is now perfect:
            if (memb == 0) return obj;
            ! And otherwise we look to see if any future entries belong in the earlier run:
            for (later=sibling(memb): later: later=sibling(later))
                if (later.list_together == lt) {
                    ! Yes, they do: so we perform a regrouping of the list and start again:
                    obj = GroupChildren(parent(obj), list_together, lt);
                    #Ifdef DBLW; print "^^Sorted to: "; DiagnoseSortList(obj); #Endif;
                    jump StartAgain;
                }
        }
    }
    return obj;
];
#Ifdef DBLW;
[ DiagnoseSortList obj memb;
    for (memb=child(obj): memb~=nothing: memb=sibling(memb)) print memb, " --> "; new_line;
];
#Endif;
```

§**9. WriteListFrom.** And here we go at last. Or at any rate we initialise the quartet of global variables detailing the current list-writing process, and begin.

```
[ WriteListFrom first style depth noactivity iter a ol;
    @push c_iterator; @push c_style; @push c_depth; @push c_margin;
    if (iter) c_iterator = iter; else c_iterator = ObjectTreeIterator;
    c_style = style; c_depth = depth;
    c_margin = 0; if (style & EXTRAINDENT_BIT) c_margin = 1;
    objectloop (a ofclass Object) {
        give a list_filter_permits;
        if ((list_filter_routine) && (list_filter_routine(a) == false))
            give a ~list_filter_permits;
    }
    first = c_iterator(first, depth, 0, START_ITF);
    if (first == nothing) {
        print (string) NOTHING__TX;
        if (style & NEWLINE_BIT ~= 0) new_line;
    } else {
        if ((noactivity) || (iter)) {
```

```
            WriteListR(first, c_depth, true);
            say__p = 1;
        } else {
            objectloop (ol provides list_together) ol.list_together = 0;
            CarryOutActivity(LISTING_CONTENTS_ACT, parent(first));
        }
    }
    @pull c_margin; @pull c_depth; @pull c_style; @pull c_iterator;
];
```

§**10. Standard Contents Listing Rule.** The default for the listing contents activity is to call this rule in its "for" stage: note that this suppresses the use of the activity, to avoid an infinite regress. The activity is used only for the default `ObjectTreeIterator`, so there is no need to specify which is used.

```
[ STANDARD_CONTENTS_LISTING_R;
    WriteListFrom(child(parameter_object), c_style, c_depth, true);
];
```

§**11. Partitioning.** Given qualifying objects $x_1, ..., x_j$, we partition them into classes of the equivalence relation $x_i \sim x_j$ if and only

(i) they both have a `plural` property (not necessarily the same), and
(ii) neither will cause the list-maker to recurse downwards to show the objects inside or on top of them, and
(iii) if they cause the list-maker to add information about whether they are worn, lighted or open, then it will add the same information about both, and
(iv) they are considered identical by the parser, in that they respond to the same syntaxes of name: so that it is impossible to find a TAKE X command such that X matches one and not the other.

The equivalence classes are numbered consecutively upwards from 1 to n, in order of first appearance in the list. For each object x_i, `partition_classes->(i-1)` is the number of its equivalence class. For each equivalence class number c, `partition_class_sizes->c` is the number of objects in this class.

```
#Ifdef DBLW;
Global DBLW_no_classes; Global DBLW_no_objs;
[ DebugPartition partition_class_sizes partition_classes first depth i k o;
    print "[Length of list is ", DBLW_no_objs, " with ", k, " plural.]^";
    print "[Partitioned into ", DBLW_no_classes, " equivalence classes.]^";
    for (i=1: i<=DBLW_no_classes : i++) {
        print "Class ", i, " has size ", partition_class_sizes->i, "^";
    }
    for (k=0, o=first: k<DBLW_no_objs : k++, o = c_iterator(o, depth, lt_value, ADVANCE_ITF)) {
        print "Entry ", k, " has class ", partition_classes->k,
            " represented by ", o, " with L=", o.list_together, "^";
    }
];
#Endif;
```

§**12. Partition List.** The following creates the `partition_classes` and `partition_class_sizes` accordingly. We return n, the number of classes.

```
[ PartitionList first no_objs depth partition_classes partition_class_sizes
    i k l n m;
    for (i=0: i<no_objs: i++) partition_classes->i = 0;
    n = 1;
    for (i=first, k=0: k<no_objs: i=c_iterator(i, depth, lt_value, ADVANCE_ITF), k++)
        if (partition_classes->k == 0) {
            partition_classes->k = n; partition_class_sizes->n = 1;
            for (l=c_iterator(i, depth, lt_value, ADVANCE_ITF), m=k+1:
                (l~=0) && (m<no_objs):
                l=c_iterator(l, depth, lt_value, ADVANCE_ITF), m++) {
                if ((partition_classes->m == 0) && (ListEqual(i, l))) {
                    if (partition_class_sizes->n < 255) (partition_class_sizes->n)++;
                    partition_classes->m = n;
                }
            }
            if (n < 255) n++;
        }
    n--;
    #Ifdef DBLW;
    DBLW_no_classes = n; DBLW_no_objs = no_objs;
    DebugPartition(partition_class_sizes, partition_classes, first, depth);
    DebugPartition(partition_class_sizes, partition_classes, first, depth);
    DebugPartition(partition_class_sizes, partition_classes, first, depth);
    #Endif;
    return n;
];
```

§**13. Equivalence Relation.** The above algorithm will fail unless `ListEqual` is indeed reflexive, symmetric and transitive, which ultimately depends on the care with which `Identical` is implemented, which in turn hangs on the `parse_noun` properties compiled by NI. But this seems to be sound.

```
[ ListEqual o1 o2;
    if ((o1.plural == 0) || (o2.plural == 0)) rfalse;
    if (child(o1) ~= 0 && WillRecurs(o1) ~= 0) rfalse;
    if (child(o2) ~= 0 && WillRecurs(o2) ~= 0) rfalse;
    if (c_style & (FULLINV_BIT + PARTINV_BIT) ~= 0) {
        if ((o1 hasnt worn && o2 has worn) || (o2 hasnt worn && o1 has worn)) rfalse;
        if ((o1 hasnt light && o2 has light) || (o2 hasnt light && o1 has light)) rfalse;
        if (o1 has container) {
            if (o2 hasnt container) rfalse;
            if ((o1 has open && o2 hasnt open) || (o2 has open && o1 hasnt open))
                rfalse;
        }
        else if (o2 has container)
            rfalse;
    }
    return Identical(o1, o2);
];
[ WillRecurs o;
```

```
    if (c_style & ALWAYS_BIT ~= 0) rtrue;
    if (c_style & RECURSE_BIT == 0) rfalse;
    if ((o has supporter) || ((o has container) && (o has open or transparent))) rtrue;
    rfalse;
];
```

§**14. Grouping.** A "group" is a maximally-sized run of one or more adjacent partition classes in the list whose first members have a common value of `list_together` which is a routine or string, and which is not equal to `lt_value`, the current grouping value. (As we see below, it's by setting `lt_value` that we restrict attention to a particular group: if we reacted to that as a `list_together` value here, then we would simply go around in circles, and never be able to see the individual objects in the group.)

For instance, suppose we have objects with `list_together` values as follows, where R_1 and R_2 are addresses of routines:

`coin` (R_1), `coin` (R_1), `box` (R_2), `statuette` (0), `coin` (R_1), `box` (R_2)

Then the partition is 1, 1, 2, 3, 1, 2, so that the final output will be something like "three coins, two boxes and a statuette" – with three grouped terms. Here each partition class is the only member in its group, so the number of groups is the same as the number of classes. (The above list is not coalesced, so the R_1 values, for instance, are not contiguous: we need to work in general with non-coalesced lists because not every iterator function will be able to coalesce fully.)

But if we have something like this:

`coin` (R_1), `Q` (R_2), `W` (R_2), `coin` (R_1), `statuette` (0), `E` (R_2), `R` (R_2)

then the partition is 1, 2, 3, 1, 4, 5, 6 and we have six classes in all. But classes 2 and 3 are grouped together, as are classes 5 and 6, so we end up with a list having just four groups: "two coins, the letters Q and W from a Scrabble set, a statuette and the letters E and R from a Scrabble set". (Again, this list has not been fully coalesced: if it had been, it would be reordered `coin`, `coin`, `Q`, `W`, `E`, `R`, `statuette`, with partition 1, 1, 2, 3, 4, 5, 6, and three groups: "two coins, the letters Q, W, E and R from a Scrabble set and a statuette".)

The reason we do not group together classes with a common non-zero `list_together` which is *not* a routine or string is that low values of `list_together` are used in coalescing the list into a pleasing order (say, moving all of the key-like items together) but not in grouping: see `list_together` in the *Inform Designer's Manual*, 4th edition.

We calculate the number of groups by starting with the number of classes and then subtracting one each time two adjacent classes share `list_together` in the above sense.

```
[ NumberOfGroupsInList o no_classes depth partition_classes partition_class_sizes
    no_groups cl memb k current_lt lt;
    no_groups = no_classes;
    for (cl=1, memb=o, k=0: cl<=no_classes: cl++) {
        ! Advance to first member of class number cl
        while (partition_classes->k ~= cl) {
            k++; memb = c_iterator(memb, depth, lt_value, ADVANCE_ITF);
        }
        if (memb) { ! In case of accidents, but should always happen
            lt = memb.list_together;
            if ((lt ~= lt_value) && (lt ofclass Routine or String) && (lt == current_lt))
                no_groups--;
            current_lt = lt;
        }
    }
    #Ifdef DBLW; print "[There are ", no_groups, " groups.]^"; #Endif;
    return no_groups;
];
```

§**15. Write List Recursively.** The big one: `WriteListR` is the heart of the list-writer.

```
[ WriteListR o depth from_start
    partition_classes partition_class_sizes
    cl memb index k2 l m no_classes q groups_to_do current_lt;
    if (o == nothing) return; ! An empty list: no output
    if (from_start) {
        o = c_iterator(o, depth, 0, COALESCE_ITF); ! Coalesce list and choose new start
    }
    o = c_iterator(o, depth, 0, SEEK_ITF); ! Find first entry in list from o
    if (o == nothing) return;
    ! Count index = length of list
    for (memb=o, index=0: memb: memb=c_iterator(memb, depth, lt_value, ADVANCE_ITF)) index++;
    if (c_style & ISARE_BIT ~= 0) {
        if (index == 1 && o hasnt pluralname) print (string) IS3__TX;
        else                                  print (string) ARE3__TX;
        if (c_style & NEWLINE_BIT ~= 0)       print ":^";
        else                                  print (char) ' ';
        c_style = c_style - ISARE_BIT;
    }
    partition_classes = RequisitionStack(index/WORDSIZE + 2);
    partition_class_sizes = RequisitionStack(index/WORDSIZE + 2);
    if ((partition_classes == 0) || (partition_class_sizes == 0))
        return RunTimeProblem(RTP_LISTWRITERMEMORY);
    no_classes =
        PartitionList(o, index, depth, partition_classes, partition_class_sizes);
    groups_to_do =
        NumberOfGroupsInList(o, no_classes, depth, partition_classes, partition_class_sizes);
    for (cl=1, memb=o, index=0, current_lt=0: groups_to_do>0: cl++) {
        ! Set memb to first object of partition class cl
        while (partition_classes->index ~= cl) {
            index++; memb=c_iterator(memb, depth, lt_value, ADVANCE_ITF);
            if (memb==0) { print "*** Error in list-writer ***^"; break; }
        }
        #Ifdef DBLW;
        ! DebugPartition(partition_class_sizes, partition_classes, o, depth);
        print "^[Class ", cl, " of ", no_classes, ": first object ", memb,
            " (", memb.list_together, "); groups_to_do ", groups_to_do, ",
            current_lt=", current_lt, " listing_size=", listing_size, "]^";
        #Endif;
        if ((memb.list_together == lt_value) ||
            (~~(memb.list_together ofclass Routine or String))) current_lt = 0;
        else {
            if (memb.list_together == current_lt) continue;
            ! Otherwise this class begins a new group
            @push listing_size;
            q = memb; listing_size = 1; l = index; m = cl;
            while (m < no_classes && q.list_together == memb.list_together) {
                m++;
                while (partition_classes->l ~= m) {
                    l++; q = c_iterator(q, depth, lt_value, ADVANCE_ITF);
```

```
                }
                if (q.list_together == memb.list_together) listing_size++;
            }
            if (listing_size > 1) {
                ! The new group contains more than one partition class
                WriteMultiClassGroup(cl, memb, depth, partition_class_sizes);
                current_lt = memb.list_together;
                jump GroupComplete;
            }
            current_lt = 0;
            @pull listing_size;
        }
        WriteSingleClassGroup(cl, memb, depth, partition_class_sizes->cl);
        .GroupComplete;
        groups_to_do--;
        if (c_style & ENGLISH_BIT ~= 0) {
            if (groups_to_do == 1) {
                if (cl <= 1) print (string) LISTAND2__TX;
                else print (string) LISTAND__TX;
            }
            if (groups_to_do > 1) print (string) COMMA__TX;
        }
    }
    FreeStack(partition_class_sizes);
    FreeStack(partition_classes);
]; ! end of WriteListR
```

§**16. Write Multiple Class Group.** The text of a single group which contains more than one partition class. We carry out the "grouping together" activity, so that the user can add text fore and aft – this is how groups of objects such as "X, Y and Z" can be fluffed up to "the letters X, Y and Z from a Scrabble set" – but the default is simple: we print the grouped items by calling `WriteListR` once again, but this time starting from X, and where `lt_value` is set to the common `list_together` value of X, Y and Z. (That restricts the list to just the objects in this group.) Because `lt_value` is set to this value, the grouping code won't then group X, Y and Z again, and they will instead be individual classes in the new list – so each will end up being sent, in turn, to `WriteSingleClassGroup` below, and *that* is where they are printed.

```
[ WriteMultiClassGroup cl memb depth partition_class_sizes q k2 l;
    ! Save the style, because the activity below is allowed to change it
    q = c_style;
    if (c_style & INDENT_BIT ~= 0) PrintSpaces(2*(depth+c_margin));
    BeginActivity(GROUPING_TOGETHER_ACT, memb);
    if (ForActivity(GROUPING_TOGETHER_ACT, memb)) {
        c_style = c_style &~ NEWLINE_BIT;
    } else {
        if (memb.list_together ofclass String) {
            ! Set k2 to the number of objects covered by the group
            k2 = 0;
            for (l=0 : l<listing_size : l++) k2 = k2 + partition_class_sizes->(l+cl);
            EnglishNumber(k2); print " ";
            print (string) memb.list_together;
            if (c_style & ENGLISH_BIT ~= 0) print " (";
```

```
            if (c_style & INDENT_BIT ~= 0)  print ":^";
        } else {
            inventory_stage = 1;
            parser_one = memb; parser_two = depth + c_margin;
            if (RunRoutines(memb, list_together) == 1) jump Omit__Sublist2;
        }
        c_margin++;
        @push lt_value; @push listing_together; @push listing_size;
        lt_value = memb.list_together; listing_together = memb;
        #Ifdef DBLW; print "^^DOWN lt_value = ", lt_value, " listing_together = ", memb, "^^";
        @push DBLW_no_classes; @push DBLW_no_objs; #Endif;
        WriteListR(memb, depth, false);
        #Ifdef DBLW; print "^^UP^^"; @pull DBLW_no_objs; @pull DBLW_no_classes; #Endif;
        @pull listing_size; @pull listing_together; @pull lt_value;
        c_margin--;
        if (memb.list_together ofclass String) {
            if (q & ENGLISH_BIT ~= 0) print ")";
        } else {
            inventory_stage = 2;
            parser_one = memb; parser_two = depth+c_margin;
            RunRoutines(memb, list_together);
        }
        .Omit__Sublist2;
    }
    EndActivity(GROUPING_TOGETHER_ACT, memb);
    ! If the NEWLINE_BIT has been forced by the activity, act now
    ! before it vanishes...
    if (q & NEWLINE_BIT ~= 0 && c_style & NEWLINE_BIT == 0) new_line;
    ! ...when the original style is restored again:
    c_style = q;
];
```

§**17. Write Single Class Group.** The text of a single group which contains exactly one partition class. Because of the way the multiple-class case recurses, every class ends up in this routine sooner or later; this is the place where the actual name of an object is printed, at long last.

```
[ WriteSingleClassGroup cl memb depth size q;
    q = c_style;
    if (c_style & INDENT_BIT) PrintSpaces(2*(depth+c_margin));
    if (size == 1) {
        if (c_style & NOARTICLE_BIT ~= 0) print (name) memb;
        else {
            if (c_style & DEFART_BIT) {
                if ((cl == 1) && (c_style & CFIRSTART_BIT)) print (The) memb;
                else print (the) memb;
            } else {
                if ((cl == 1) && (c_style & CFIRSTART_BIT)) print (CIndefArt) memb;
                else print (a) memb;
            }
        }
    } else {
```

```
        if (c_style & DEFART_BIT) {
            if ((cl == 1) && (c_style & CFIRSTART_BIT)) PrefaceByArticle(memb, 0, size);
            else PrefaceByArticle(memb, 1, size);
        }
        @push listing_size; listing_size = size;
        CarryOutActivity(PRINTING_A_NUMBER_OF_ACT, memb);
        @pull listing_size;
    }
    if ((size > 1) && (memb hasnt pluralname)) {
        give memb pluralname;
        WriteAfterEntry(memb, depth);
        give memb ~pluralname;
    } else WriteAfterEntry(memb, depth);
    c_style = q;
];
```

§**18. Write After Entry.** Each entry can be followed by supplementary, usually parenthetical, information: exactly what, depends on the style. The extreme case is when the style, and the object, call for recursion to list the object-tree contents: this is achieved by calling `WriteListR`, using the `ObjectTreeIterator` (whatever the iterator used at the top level) and increasing the depth by 1.

```
[ WriteAfterEntry o depth
    p recurse_flag parenth_flag eldest_child child_count combo;
    inventory_stage = 2;
    if (c_style & PARTINV_BIT) {
        BeginActivity(PRINTING_ROOM_DESC_DETAILS_ACT);
        if (ForActivity(PRINTING_ROOM_DESC_DETAILS_ACT) == false) {
        combo = 0;
        if (o has light && location hasnt light) combo=combo+1;
        if (o has container && o hasnt open)     combo=combo+2;
        if ((o has container && (o has open || o has transparent))
            && (child(o)==0))                    combo=combo+4;
        if (combo) L__M(##ListMiscellany, combo, o);
        }
        EndActivity(PRINTING_ROOM_DESC_DETAILS_ACT);
    }   ! end of PARTINV_BIT processing
    if (c_style & FULLINV_BIT) {
        if (o has light && o has worn) { L__M(##ListMiscellany, 8);     parenth_flag = true; }
        else {
            if (o has light)           { L__M(##ListMiscellany, 9, o);  parenth_flag = true; }
            if (o has worn)            { L__M(##ListMiscellany, 10, o); parenth_flag = true; }
        }
        if (o has container)
            if (o has openable) {
                if (parenth_flag) {
                    #Ifdef SERIAL_COMMA; print ","; #Endif;
                    print (string) AND__TX;
                } else            L__M(##ListMiscellany, 11, o);
                if (o has open)
                    if (child(o)) L__M(##ListMiscellany, 12, o);
                    else          L__M(##ListMiscellany, 13, o);
                else
```

```

    }
    ".";
];
```

WorldModel Template B/wmt

Purpose

Testing and changing the fundamental spatial relations.

---

§**1. The Core Tree.** Whereas I6 traditionally has a simple object tree hierarchy for containment, support, carrying and so on, the I7 template also uses the `component_*` properties to provide a second tree which defines the "part of" relation. These two trees interact in a subtle way, and it took a very long time to work out the simplest way to express this.

The *core* of an object is the root of its subtree in the component relation tree. So for a television set with a control panel which has a button on, the core for the button (and also for the panel and the set) will be the set. When X is a part of Y, it must be spatially in the same position as Y, and so the spatial location of X is determined by the position in the object tree of its core. (In effect, the spatial situation can be found by contracting together all nodes corresponding to objects which are parts of each other, but it would waste memory to construct such a tree: `CoreOfParentOfCoreOf` simulates what the `parent` operation would be in such a tree if it existed, wasting a little time instead.)

The *holder* of an object is its component parent, if it is part of something, or its object-tree parent if it has one. It is illegal for both of these to be non-`nothing`, so this is unambiguous.

```
[ HolderOf o;
    if (o && (o.component_parent)) return o.component_parent;
    if (o && (parent(o))) return parent(o);
    return nothing;
];
[ ParentOf o;
    if (o) o = parent(o);
    return o;
];
[ CoreOf o;
    while (o && (o provides component_parent) && (o.component_parent)) o = o.component_parent;
    return o;
];
[ CoreOfParentOfCoreOf o;
    while (o && (o provides component_parent) && (o.component_parent)) o = o.component_parent;
    if (o) o = parent(o);
    while (o && (o provides component_parent) && (o.component_parent)) o = o.component_parent;
    return o;
];
```

§**2. Climbing the Core Tree.** `LocationOf` returns the room in which an object can be found, or `nothing` if it is out of play. For this purpose a backdrop has no location, there being no canonical choice to make, while a two-sided door is in its "front side" (see below). Directions and regions are always out of play. For a room, `LocationOf` is necessarily itself.

`CommonAncestor` finds the nearest object indirectly containing `o1` and `o2`, or returns `nothing` if there is no common ancestor. (This is a port of `CommonAncestor` from the I6 library, adapted to work on the core tree.)

```
[ LocationOf o;
    if (~~(O ofclass K1_room or K2_thing)) return nothing;
    if (O ofclass K4_door) return FrontSideOfDoor(O);
    if (O ofclass K7_backdrop) return nothing;
    while (o) {
        if (o ofclass K1_room) return o;
        o = CoreOfParentOfCoreOf(o);
    }
    return nothing;
];
[ CommonAncestor o1 o2 i j;
    o1 = CoreOf(o1);
    o2 = CoreOf(o2);
    for (i=o1: i: i = CoreOfParentOfCoreOf(i))
        for (j=o2: j: j = CoreOfParentOfCoreOf(j))
            if (j == i) return j;
    return nothing;
];
[ IndirectlyContains o1 o2;
    if ((o1 == nothing) || (o2 == nothing)) rfalse;
    if ((o1 ofclass K1_room) && (o2 ofclass K4_door)) {
        if (o1 == FrontSideOfDoor(o2)) rtrue;
        if (o1 == BackSideOfDoor(o2)) rtrue;
        rfalse;
    }
    if (o2 ofclass K7_backdrop) rfalse;
    for (o2 = HolderOf(o2) : o2: o2 = HolderOf(o2)) if (o2 == o1) rtrue;
    rfalse;
];
```

§**3. To Decide Whether In.** A curiosity, this: the I6 definition of "To decide whether in (obj - object)". As can be seen, there are three possible interpretations of "in", depending on the kind of object, so this could all be done with three different definitions in the Standard Rules, so that run-time type checking would decide which to apply: but that would produce a little overhead and make the code for this rather common operation a bit complicated. Besides, this way we can produce a respectable run-time problem message when the phrase is misapplied.

Note that "in X" is not equivalent to "the player is in X": the latter uses direct containment, whereas we use indirect containment. Thus "in the Hall" and "in the laundry-basket" are both true if the player is in a laundry-basket in the Hall.

```
[ WhetherIn obj;
    if (obj has enterable) {
        if (IndirectlyContains(obj, player)) rtrue;
        rfalse;
    }
    if (obj ofclass K9_region) return TestRegionalContainment(real_location, obj);
    if (obj ofclass K1_room) {
        if (obj == real_location) rtrue;
        rfalse;
    }
    RunTimeProblem(RTP_NOTINAROOM, obj);
    rfalse;
];
```

§**4. Containment Relation.** This is the single most important relation in I7: direct containment. It is complicated by the fact that "A is in B" is represented differently at run-time when A is a room and B is a region, and when it isn't.

For each A there is at most one B such that "A is in B" is true. Because of this we test the relation with a function of one variable which turns A into B, rather than a function of two variables returning true or false. `ContainerOf` is that function.

I7 frequently needs to compile loops over all A such that "A is in B". In simpler relations (such as the support relation below) it can do this efficiently by iterating through the object-tree children of B, but for containment we have to provide an iterator function `TestContainmentRange`, as otherwise we would get the wrong result when B is a region.

```
[ ContainerOf A p;
    if (A ofclass K1_room) return A.map_region;
    p = parent(A);
    if (p == nothing) return nothing;
    if (p ofclass K5_container) return p;
    if (p ofclass K1_room) return p;
    if (p ofclass K9_region) return p;
    return nothing;
];
[ TestContainmentRange obj e f;
    if (obj ofclass K9_region) {
        objectloop (f ofclass K1_room && f.map_region == obj)
            if (f > e) return f;
        return nothing;
    }
    if (obj ofclass K5_container or K1_room) {
        if (e == nothing) return child(obj);
```

```
        return sibling(e);
    }
    return nothing;
];
```

§**5. Support Relation.** This then is simpler, with no need for an iterator governing searches.

```
[ SupporterOf obj p;
    p = parent(obj);
    if (p == nothing) return nothing;
    if (p ofclass K6_supporter) return p;
    return nothing;
];
```

§**6. Carrying Relation.** Only people may carry, and something worn is not in this sense carried.

```
[ CarrierOf obj p;
    p = parent(obj);
    if (p && (p ofclass K8_person) && (obj hasnt worn)) return p;
    return nothing;
];
```

§**7. Wearing Relation.** Only people may wear.

```
[ WearerOf obj p;
    p = parent(obj);
    if (p && (p ofclass K8_person) && (obj has worn)) return p;
    return nothing;
];
```

§**8. Having Relation.** A person has something if and only if he either wears or carries it.

```
[ OwnerOf obj p;
    p = parent(obj);
    if (p && (p ofclass K8_person)) return p;
    return nothing;
];
```

§**9. Making Parts.** Note that `MakePart` removes the part-to-be from the object tree before attaching it: it cannot, of course, be the core of the resulting object.

```
[ MakePart P Of First;
    if (parent(P)) remove P; give P ~worn;
    if (Of == nothing) { DetachPart(P); return; }
    if (P.component_parent) DetachPart(P);
    P.component_parent = Of;
    First = Of.component_child;
    Of.component_child = P; P.component_sibling = First;
];
[ DetachPart P From Daddy O;
    Daddy = P.component_parent; P.component_parent = nothing;
    if (Daddy == nothing) { P.component_sibling = nothing; return; }
    if (Daddy.component_child == P) {
        Daddy.component_child = P.component_sibling;
        P.component_sibling = nothing; return;
    }
    for (O = Daddy.component_child: O: O = O.component_sibling)
        if (O.component_sibling == P) {
            O.component_sibling = P.component_sibling;
            P.component_sibling = nothing; return;
        }
];
```

§**10. Movements.** Note that an object is detached from its component parent, if it has one, when moved.

```
[ MoveObject F T opt going_mode was;
    if (F == nothing) return RunTimeProblem(RTP_CANTMOVENOTHING);
    if (F ofclass K7_backdrop) {
        if (T ofclass K9_region) {
            give F ~absent; F.found_in = T.regional_found_in;
            if (TestRegionalContainment(LocationOf(player), T)) move F to LocationOf(player);
            else remove F;
            return; }
        return RunTimeProblem(RTP_BACKDROP, F, T);
    }
    if (~~(F ofclass K2_thing)) return RunTimeProblem(RTP_NOTTHING, F, T);
    if (T ofclass K9_region) return RunTimeProblem(RTP_NOTBACKDROP, F, T);
    if (F has worn) {
        give F ~worn;
        if (F in T) return;
    }
    DetachPart(F);
    if (going_mode == false) {
        if (F == player) { PlayerTo(T, opt); return; }
        if ((IndirectlyContains(F, player)) && (LocationOf(player) ~= LocationOf(T))) {
            was = parent(player);
            move player to real_location;
            move F to T;
            PlayerTo(was, true);
            return;
```

```
        }
    }
    move F to T;
];
[ RemoveFromPlay F;
    if (F == nothing) return RunTimeProblem(RTP_CANTREMOVENOTHING);
    if (F == player) return RunTimeProblem(RTP_CANTREMOVEPLAYER);
    if (F ofclass K4_door) return RunTimeProblem(RTP_CANTREMOVEDOORS);
    give F ~worn; DetachPart(F);
    if (F ofclass K7_backdrop) give F absent;
    remove F;
];
```

§**11. On Stage.** The following implements the "on-stage" and "off-stage" adjectives provided by the Standard Rules. Here, as above, note that the I6 attribute `absent` marks a floating object (see below) which has been removed from play; in I7 only doors and backdrops are allowed to float, and only backdrops are allowed to be removed from play.

```
[ OnStage O x;
    if (O ofclass K1_room) rfalse;
    while (metaclass(O) == Object) {
        if (O ofclass K1_room) rtrue;
        if (O ofclass K9_region) rfalse;
        if (O ofclass K4_door) rtrue;
        if (O ofclass K7_backdrop) { if (O has absent) rfalse; rtrue; }
        x = O.component_parent; if (x) { O = x; continue; }
        x = parent(O); if (x) { O = x; continue; }
        rfalse;
    }
    rfalse;
];
```

§**12. Moving the Player.** Note that the player object can only be moved by this routine: this allows us to maintain the invariant for `real_location` and `location` (for which, see "Light.i6t") and to ensure that multiply-present objects can be witnessed where they need to be.

```
[ PlayerTo newplace flag;
    @push actor; actor = player;
    move player to newplace;
    location = LocationOf(newplace);
    real_location = location;
    MoveFloatingObjects();
    ADJUST_LIGHT_R(1);
    DivideParagraphPoint();
    if (flag == 0) <Look>;
    if (flag == 1) give location visited;
    if (flag == 2) AbbreviatedRoomDescription();
    @pull actor;
];
```

§13. Move During Going. The following routine preserves the invariant for `real_location`, but gets `location` wrong since it doesn't adjust for light. Nor are floating objects moved. It should be used only in the course of other operations which get the rest of this right. (I7 uses it only for the "going" action, where these various operations are each handled by different named rules to increase the flexibility of the system.)

```
[ MoveDuringGoing F T;
    MoveObject(F, T, 0, true);
    if (actor == player) {
        location = LocationOf(player);
        real_location = location;
    }
];
```

§14. Being Everywhere. The following is used as the `found_in` property for any backdrop which is "everywhere", that is, which is found in every room.

```
[ FoundEverywhere; rtrue; ];
```

§15. Changing the Player. It is very important that nobody simply change the value of the `player` variable, because so much else must be updated when the identity of the player changes: the light situation, floating objects, the `real_location` and so on. Because of this, the NI compiler contains code which compiles an assertion of the proposition "is(`player`, X)" into a function call `ChangePlayer(X)` rather than a variable assignment `player = X`. So we cannot catch out the system by writing "now the player is Mr Henderson".

We must ensure that if `player` is initially X, is changed to Y, and is then changed back to X, that both X and Y end exactly as they began – hence the flummery below with using `remove_proper` to ensure that `proper` is left with the correct value. Note that:

(1) at any given time exactly one person has the I6 `concealed` attribute: the current player;
(2) the `selfobj` is the default initial value of `player`, and because it has as its actual printed name "yourself", we need to override this when something else takes over as player: we change to "your former self", in fact. No such device is needed for other people being changed from because they are explicitly given printed names – say "Mr Darcy", "the sous-chef", etc. – in the source text.

```
[ ChangePlayer obj flag i;
    if (~~(obj ofclass K8_person)) return RunTimeProblem(RTP_CANTCHANGE, obj);
    if (~~(OnStage(obj))) return RunTimeProblem(RTP_CANTCHANGEOFFSTAGE, obj);
    if (obj == player) return;
    give player ~concealed;
    if (player has remove_proper) give player ~proper;
    if (player == selfobj) {
        player.saved_short_name = player.short_name; player.short_name = FORMER__TX;
    }
    player = obj;
    if (player == selfobj) {
        player.short_name = player.saved_short_name;
    }
    if (player hasnt proper) give player remove_proper; ! when changing out again
    give player concealed proper;
    location = LocationOf(player); real_location = location;
    MoveFloatingObjects();
    SilentlyConsiderLight();
];
```

§**16. Floating Objects.** A single object can only be in one position in the object tree, yet backdrops and doors must be present in multiple rooms. This is accomplished by making them, in I6 jargon, "floating objects": objects which move in the tree whenever the player does, so that – from the player's perspective – they are always present when they should be. In I6, almost anything can be made a floating object, but in I7 this is strictly and only used for backdrops and two-sided doors.

There are several conceptual problems with this scheme: chiefly that it assumes that the only witness to the spatial arrangement of objects is the player. In I6 that was usually true, but in I7, where every person can undertake actions, it really isn't true any longer: if the objects float to follow the player, it means that they are not present with other people who might need to interact with them. This is why the accessibility rules are somewhat hacked for backdrops and doors (see "Light.i6t"). In fact we generally achieve the illusion we want, but this is largely because it is difficult to catch out all the exceptions for backdrops and doors, and because in practice authors tend not to set things up so that the presence or absence of backdrops much affects what non-player characters do.

All the same, the scheme is not logically defensible, and this is why we do not allow the user to create new categories of floating objects in I7.

The I6 implementation of `MoveFloatingObjects` acted on the `location` rather than the `real_location`, which (a) meant that multiply-present objects could include `thedark` – the generic Darkness place – as one possible location, but (b) assumed that the only sense by which the player could witness an object was sight. In I7, `thedark` is not a valid room, and we are a bit more careful about the senses.

```
[ MoveFloatingObjects i k l m address flag;
    if (real_location == nothing) return;
    objectloop (i) {
        address = i.&found_in;
        if (address ~= 0 && i hasnt absent) {
            if (ZRegion(address-->0) == 2) {
                m = address-->0;
                .TestPropositionally;
                if (m.call(real_location) ~= 0) move i to real_location;
                else remove i;
            }
            else {
                k = i.#found_in;
                for (l=0 : l<k/WORDSIZE : l++) {
                    m = address-->l;
                    if (ZRegion(m) == 2) jump TestPropositionally;
                    if (m == real_location || m in real_location) {
                        if (i notin real_location) move i to real_location;
                        flag = true;
                    }
                }
                if (flag == false) { if (parent(i)) remove i; }
            }
        }
    }
];
[ MoveBackdrop bd D x address;
    if (~~(bd ofclass K7_backdrop)) return RunTimeProblem(RTP_BACKDROPONLY, bd);
    if (bd.#found_in > WORDSIZE) {
        address = bd.&found_in;
        address-->0 = D;
    } else bd.found_in = D;
```

```
    give bd ~absent;
    MoveFloatingObjects();
];
```

§**17. Wearing Clothes.** An object X is worn by a person P if and only if (i) the object tree `parent` of X is P, and (ii) X has the `worn` attribute. In fact for I7 purposes we are careful to ensure that (ii) happens only when (i) does in any case: if X is moved in the object tree, or made a part of something, or removed from play, then `worn` is removed.

```
[ WearObject X P opt;
    if (X == false) rfalse;
    if (X notin P) MoveObject(X, P, opt);
    give X worn;
];
```

§**18. Map Connections.** `MapConnection` returns the room which is in the given direction (as an object) from the given room: it is used, among other things, to test the "mapped east of" and similar relations. (The same relations are asserted true with `AssertMapConnection` and false with `AssertMapUnconnection`.)

`RoomOrDoorFrom` returns either the room or door which is in the given direction, and is thus simpler (since it doesn't have to investigate what is through such a door).

Both routines return values which are type-safe in I7 provided the kind of value they are assigned to is "object": neither returns any specific kind of object without fail. (`MapConnection` is always either a door or `nothing`, but `nothing` is not a typesafe value for "door".)

Note that map connections via doors are immutable.

```
[ MapConnection from_room dir
    in_direction through_door;
    if ((from_room ofclass K1_room) && (dir ofclass K3_direction)) {
        in_direction = Map_Storage-->
            ((from_room.IK_1)*No_Directions + dir.IK_3);
        if (in_direction ofclass K1_room) return in_direction;
        if (in_direction ofclass K4_door) {
            @push location;
            location = from_room;
            through_door = in_direction.door_to();
            @pull location;
            if (through_door ofclass K1_room) return through_door;
        }
    }
    return nothing;
];
[ DoorFrom obj dir rv;
    rv = RoomOrDoorFrom(obj, dir);
    if (rv ofclass K4_door) return rv;
    return nothing;
];
[ RoomOrDoorFrom obj dir use_doors in_direction sl through_door;
    if ((obj ofclass K1_room) && (dir ofclass K3_direction)) {
        in_direction = Map_Storage-->
            ((obj.IK_1)*No_Directions + dir.IK_3);
        if (in_direction ofclass K1_room or K4_door) return in_direction;
```

```
    }
    return nothing;
];
[ AssertMapConnection r1 dir r2 in_direction;
    SignalMapChange();
    in_direction = Map_Storage-->
        ((r1.IK_1)*No_Directions + dir.IK_3);
    if ((in_direction == 0) || (in_direction ofclass K1_room)) {
        Map_Storage-->((r1.IK_1)*No_Directions + dir.IK_3) = r2;
        return;
    }
    if (in_direction ofclass K4_door) {
        RunTimeProblem(RTP_EXITDOOR, r1, dir);
        return;
    }
    RunTimeProblem(RTP_NOEXIT, r1, dir);
];
[ AssertMapUnconnection r1 dir r2 in_direction;
    SignalMapChange();
    in_direction = Map_Storage-->
        ((r1.IK_1)*No_Directions + dir.IK_3);
    if (r1 ofclass K4_door) {
        RunTimeProblem(RTP_EXITDOOR, r1, dir);
        return;
    }
    if (in_direction == r2)
        Map_Storage-->((r1.IK_1)*No_Directions + dir.IK_3) = 0;
    return;
];
```

§**19. Adjacency Relation.** A relation between two rooms which, note, does not see connections through doors.

```
[ TestAdjacency R1 R2 i row;
    row = (R1.IK_1)*No_Directions;
    for (i=0: i<No_Directions: i++, row++)
        if (Map_Storage-->row == R2) rtrue;
    rfalse;
];
```

§**20. Regional Containment Relation.** This tests whether an object with a definite physical location is in a given region. (For a two-sided door which straddles regions, the front side is what counts; for a backdrop, a direction or another region, the answer is always no.) We rely on the fact that every room object has a `map_region` property which is the smallest region containing it, if any does, and `nothing` otherwise; region objects are then in the object tree such that parenthood corresponds to spatial containment. (Note that in I7, a region must either completely contain another region, or else have no overlap with it.)

```
[ TestRegionalContainment obj region o;
    if ((obj == nothing) || (region == nothing)) rfalse;
    if (~~(obj ofclass K1_room)) obj = LocationOf(obj);
    if (obj == nothing) rfalse;
    o = obj.map_region;
    while (o) {
        if (o == region) rtrue;
        o = parent(o);
    }
    rfalse;
];
```

§**21. Doors.** There are two sorts of door: one-sided and two-sided.

A two-sided door is in two rooms at once: one is called the front side, the other the back side. The front side is the one declared first in the source. Note that a one-sided door is also an I6 object of class `K4_door`, and then the front side is the room holding it, while the back side is `nothing`.

The `door_to` property calculates the room which the door leads to; that of course depends on which side of it the player is standing. Similarly, `door_dir` calculates the direction it leads in. Unlike the I6 setup, where `door_dir` returned the direction property (`n_to`, `s_to`, etc.), here in I7's template it returns the direction object (`n_obj`, `s_obj`, etc.)

```
[ FrontSideOfDoor D; if (~~(D ofclass K4_door)) rfalse;
    if (D provides found_in) return (D.&found_in)-->0; ! Two-sided
    return parent(D); ! One-sided
];
[ BackSideOfDoor D; if (~~(D ofclass K4_door)) rfalse;
    if (D provides found_in) return (D.&found_in)-->1; ! Two-sided
    return nothing; ! One-sided
];
[ OtherSideOfDoor D from_room rv;
    if (D ofclass K4_door) {
        @push location;
        location = LocationOf(from_room);
        rv = D.door_to();
        @pull location;
    }
    return rv;
];
[ DirectionDoorLeadsIn D from_room rv dir;
    if (D ofclass K4_door) {
        @push location;
        location = LocationOf(from_room);
        rv = D.door_dir();
        @pull location;
    }
```

```
    return rv;
];
```

§**22. Visibility Relation.** We use `TestScope` to decide whether there is a line of sight from A to B; it's a relation which cannot be asserted true or false.

```
[ TestVisibility A B;
    if (~~OffersLight(parent(CoreOf(A)))) rfalse;
    if (suppress_scope_loops) rtrue;
    return TestScope(B, A);
];
```

§**23. Touchability Relation.** We use `ObjectIsUntouchable` to decide whether there is physical access from A to B; it's a relation which cannot be asserted true or false.

```
[ TestTouchability A B;
    if (TestScope(B,A) == false) rfalse;
    if (ObjectIsUntouchable(B, 1, 0, A)) rfalse;
    rtrue;
];
```

§**24. Concealment Relation.** An activity determines whether one object conceals another; it's a relation which cannot be asserted true or false.

```
[ TestConcealment A B;
    if (A ofclass K2_thing && B ofclass K2_thing) {
        particular_possession = B;
        if (CarryOutActivity(DECIDING_CONCEALED_POSSESS_ACT, A)) rtrue;
    }
    rfalse;
];
```

Light Template B/light

Purpose

The determination of light, visibility and physical access.

§**1. Darkness.** "Darkness" is not really a place: but in I6 it has to be an object so that the location-name on the status line can be "Darkness". In I7 we use it as little as possible: note that it has no properties.

```
Object thedark "(darkness object)";
```

§**2. Light Measurement.** These two routines, `OffersLight` and `HasLightSource`, are largely unchanged from their I6 definitions; see the *Inform Designer's Manual*, 4th edition, for a commentary. In terms of how they are used in I7, `OffersLight` is called only by the two rules below; `HasLightSource` is called also in determining the scope, that is, what is visible to the player.

```
[ OffersLight obj j;
    while (obj) {
        if (obj has light) rtrue;
        objectloop (j in obj) if (HasLightSource(j)) rtrue;
        if ((obj has container) && (obj hasnt open) && (obj hasnt transparent)) rfalse;
        if ((obj provides component_parent) && (obj.component_parent))
            obj = obj.component_parent;
        else
            obj = parent(obj);
    }
    rfalse;
];
[ HasLightSource i j ad sr po;
    if (i == 0) rfalse;
    if (i has light) rtrue;
    if ((IsSeeThrough(i)) && (~~(HidesLightSource(i))))
        objectloop (j in i)
            if (HasLightSource(j)) rtrue;
    ad = i.&add_to_scope;
    if (parent(i) ~= 0 && ad ~= 0) {
        if (metaclass(ad-->0) == Routine) {
            ats_hls = 0; ats_flag = 1;
            sr = scope_reason; po = parser_one;
            scope_reason = LOOPOVERSCOPE_REASON; parser_one = 0;
            RunRoutines(i, add_to_scope);
            scope_reason = sr; parser_one = po;
            ats_flag = 0; if (ats_hls == 1) rtrue;
        }
        else {
            for (j=0 : (WORDSIZE*j)<i.#add_to_scope : j++)
                if ((ad-->j) && (HasLightSource(ad-->j) == 1)) rtrue;
```

```
        }
    }
    if (ComponentHasLight(i)) rtrue;
    rfalse;
];
[ ComponentHasLight o obj next_obj;
    if (o provides component_child) {
        obj = o.component_child;
        while (obj) {
            next_obj = obj.component_sibling;
            if (obj has light) rtrue;
            if (HasLightSource(obj)) rtrue;
            if ((obj provides component_child) && (ComponentHasLight(obj))) rtrue;
            obj = next_obj;
        }
    }
    rfalse;
];
[ HidesLightSource obj;
    if (obj == player) rfalse;
    if (obj has transparent or supporter) rfalse;
    if (obj has animate) rfalse;
    if (obj has container) return (obj hasnt open);
    return (obj hasnt enterable);
];
```

§**3. Invariant.** The following routines maintain two variables about the light condition of the player:

(a) If on the most recent check the player was in light, then `location` equals `real_location` and `lightflag` is false.

(b) If on the most recent check the player was in darkness, then `location` equals `thedark` and `lightflag` is true.

Note that they are not allowed to alter `real_location`, whose definition has nothing to do with light.

```
Global lightflag = false;
```

§**4. Adjust Light Rule.** This rule fires at least once a turn, and more often when the player moves location, since that's likely to invalidate any previous assumptions. It compares the state of light now with the last time it ran, and gives instructions on what to do in each of the four possibilities.

```
[ ADJUST_LIGHT_R previous_light_condition;
    previous_light_condition = lightflag;
    lightflag = OffersLight(parent(player));
    if ((previous_light_condition == false) && (lightflag == false)) {
        location = thedark;
        rfalse;
    }
    if ((previous_light_condition == false) && (lightflag == true)) {
        location = real_location;
        CarryOutActivity(PRINTING_NEWS_OF_LIGHT_ACT);
        rfalse;
    }
    if ((previous_light_condition == true) && (lightflag == false)) {
        location = thedark;
        DivideParagraphPoint();
        BeginActivity(PRINTING_NEWS_OF_DARKNESS_ACT);
        if (ForActivity(PRINTING_NEWS_OF_DARKNESS_ACT) == false) L__M(##Miscellany, 9);
        EndActivity(PRINTING_NEWS_OF_DARKNESS_ACT);
        rfalse;
    }
    if ((previous_light_condition == true) && (lightflag == true)) {
        location = real_location;
        rfalse;
    }
    rfalse;
];
```

§**5. Silent Light Consideration.** The Adjust Light Rule makes a fuss when light changes: it prints messages, for instance. This rule is silent instead, and simply does the minimum necessary to maintain the light invariant. It is used in only three circumstances:

(a) To determine the initial light condition at start of play.
(b) When the player moves from one room to another via the "going" action.
(c) When the player changes from one persona to another.

Perhaps case (b) is surprising. Why not simply use the adjust light rule, as we do on an instance of "move player to ...", for instance? The answer is that the going action is just about to print details of the new location anyway, so it would be redundant to have the adjust light rule print out details as well.

```
[ SilentlyConsiderLight;
    lightflag = OffersLight(parent(player));
    if (lightflag) location = real_location; else location = thedark;
    rfalse;
];
```

§**6. Translucency.** `IsSeeThrough` is used at various places: roughly speaking, it determines whether `obj` being in scope means that the object-tree contents of `obj` are in scope.

```
[ IsSeeThrough obj;
    if ((obj has supporter)
        || (obj has transparent)
        || (obj has animate)
        || ((obj has container) && (obj has open)))
        rtrue;
rfalse;
];
```

§**7. Visibility Parent.** The idea of `VisibilityParent` is that it takes us from a given position in the object tree, `o`, to the next visible position above. Note that

(1) A container has an inside and an outside: this routine calculates from the "inside of `o`", which is why it returns `nothing` from an opaque closed container;
(2) Component parts are (for purposes of this routine) attached to the outside surface of a container, so that if `o` is part of a closed opaque container then the visibility parent of `o` is its actual parent.

```
[ VisibilityParent o;
    if (o && (o has container) && (o hasnt open) && (o hasnt transparent)) return nothing;
    if (o) o = CoreOfParentOfCoreOf(o);
    return o;
];
```

§**8. Find Visibility Levels.** The following routine sets the pair of variables `visibility_ceiling`, the highest visible point in the object tree above the player – or `thedark` if the player cannot see at all – and `visibility_levels`, the number of steps of `VisibilityParent` needed to reach this ceiling; or 0 if the player cannot see at all.

```
[ FindVisibilityLevels lc up;
    if (location == thedark) {
        visibility_ceiling = thedark;
        visibility_levels = 0;
    } else {
        visibility_ceiling = player;
        while (true) {
            up = VisibilityParent(visibility_ceiling);
            if (up == 0) break;
            visibility_ceiling = up;
            lc++;
        }
        visibility_levels = lc;
    }
];
```

§**9. Scope Ceiling.** Scope is almost the same thing as visibility, but not quite, and the following routine does not quite duplicate the calculation of `FindVisibilityLevels`. The difference arises in the first step, where we take the `parent` of `pos`, not the core of the `parent` of the core of `pos`: this makes a difference if `pos` is inside a container which is itself part of something else.

```
[ ScopeCeiling pos c;
    if (pos == player && location == thedark) return thedark;
    c = parent(pos);
    if (c == 0) return pos;
    while (VisibilityParent(c)) c = VisibilityParent(c);
    return c;
];
```

§**10. Object Is Untouchable.** The following routine imitates the I6 library one of the same name, but works instead by delegating the decision to the accessibility rulebook.

It is not easy to answer the question of whether someone other than the player, but in another room, can touch a multiply-present object (a two-sided door or a backdrop) and we err on the side of caution by saying yes in such cases. The question would only be asked in the case of a "try" action deliberately caused by the author, or by an instruction made by the player to someone not in the same room: in the first case, we will assume that the author knows what he is doing, and in the second case, the circumstances in which saying yes would be a wrong call are *highly* improbable.

```
[ ObjectIsUntouchable item silent_flag flag2 p save_sp decision;
    if ((p ~= player) && (LocationOf(p) ~= LocationOf(player)) &&
        ((item ofclass K4_door) || (item ofclass K7_backdrop))) {
        decision = false;
    } else {
        untouchable_object = item; untouchable_silence = silent_flag;
        touch_persona = p; if (p == actor) touch_persona = 0;
        save_sp = say__p; say__p = 0;
        if (ProcessRulebook(ACCESSIBILITY_RB, 0, true)) {
            if (RulebookSucceeded()) decision = false;
            else decision = true;
        } else decision = false;
        if (say__p == false) say__p = save_sp;
    }
    untouchable_silence = 0;
    return decision;
];
```

§11. Access Through Barriers Rule.

```
[ ACCESS_THROUGH_BARRIERS_R ancestor i j external p;
    p = touch_persona; if (p == 0) p = actor;
    ancestor = CommonAncestor(p, untouchable_object);
    if ((ancestor == 0) && (LocationOf(untouchable_object) == nothing)
        && ((untouchable_object ofclass K4_door or K7_backdrop) == false)) {
        if (touch_persona == 0) GL__M(##Take,8,untouchable_object);
        RulebookFails();
        rtrue;
    }
    ! First, a barrier between the player and the ancestor.
    if (CoreOf(p) ~= ancestor) {
        i = parent(CoreOf(p)); j = CoreOf(i); external = false;
        if (j ~= i) { i = j; external = true; }
        while (i~=ancestor && i) {
            if ((external == false)
                && (ProcessRulebook(REACHING_OUTSIDE_RB, i))
                && (RulebookFailed())) rtrue; ! Barrier
            i = parent(CoreOf(i)); j = CoreOf(i); external = false;
            if (j ~= i) { i = j; external = true; }
        }
    }
    ! Second, a barrier between the item and the ancestor.
    if (CoreOf(untouchable_object) ~= ancestor) {
        ! We can always get to the core of the item.
        i = CoreOf(untouchable_object);
        ! This will be on the inside of its parent, if its parent is a
        ! container, so there should be no exemption.
        i = parent(i); external = false;
        ! j = CoreOf(i); if (j ~= i) { i = j; external = true; }
        while (i~=ancestor && i) {
            if ((external == false) &&
                (ProcessRulebook(REACHING_INSIDE_RB, i)) &&
                (RulebookFailed())) rtrue; ! Barrier
            i = CoreOf(i);
            if (i == ancestor) break;
            i = parent(i); j = CoreOf(i); external = false;
            if (j ~= i) { i = j; external = true; }
        }
    }
    RulebookSucceeds(); ! No barrier
    rtrue;
];
```

§12. Can't Reach Inside Closed Containers Rule.

```
[ CANT_REACH_INSIDE_CLOSED_R;
    if (parameter_object has container && parameter_object hasnt open) {
        if (touch_persona == 0) GL__M(##Take,9,parameter_object);
        RulebookFails(); rtrue;
    }
    rfalse;
];
```

§13. Can't Reach Outside Closed Containers Rule.

```
[ CANT_REACH_OUTSIDE_CLOSED_R;
    if (parameter_object has container && parameter_object hasnt open) {
        if (touch_persona == 0) GL__M(##Take,9,parameter_object);
        RulebookFails(); rtrue;
    }
    rfalse;
];
```

§14. Can't Reach Inside Rooms Rule.

```
[ CANT_REACH_INSIDE_ROOMS_R;
    if (parameter_object && parameter_object ofclass K1_room) {
        if (touch_persona == 0) GL__M(##Take,14,parameter_object);
        RulebookFails(); rtrue;
    }
    rfalse;
];
```

Tests Template B/testt

Purpose

The command grammar and I6 implementation for testing commands such as TEST, ACTIONS and PURLOIN.

---

§**1. Abstract Command.** The code below is compiled only if the symbol `DEBUG` is defined, which it always is for normal runs in the Inform user interface, but not for Release runs.

Not all of these commands are documented; this is intentional. They may be changed in name or function. This is all of the testing commands except for the GLKLIST command, which is in Glulx.i6t (and does not exist when the target VM is the Z-machine).

We take the commands in alphabetical order, beginning with ABSTRACT, which moves an object to a new position in the object tree.

```
[ XAbstractSub;
    if (XTestMove(noun, second)) return;
    move noun to second;
    "[Abstracted.]";
];
[ XTestMove obj dest;
    if ((obj <= InformLibrary) || (obj == LibraryMessages))
        "[Can't move ", (name) obj, ": it's a system object.]";
    if (obj.component_parent)
        "[Can't move ", (name) obj, ": it's part of ",
        (the) obj.component_parent, ".]";
    while (dest) {
        if (dest == obj) "[Can't move ", (name) obj, ": it would contain itself.]";
        dest = CoreOfParentOfCoreOf(dest);
    }
    rfalse;
];
```

§**2. Actions Command.** ACTIONS turns tracing of actions on.

```
[ ActionsOnSub; trace_actions = 1; say__p = 1; "Actions listing on."; ];
[ ActionsOffSub; trace_actions = 0; say__p = 1; "Actions listing off."; ];
```

§**3. Gonear Command.** GONEAR teleports the player to the vicinity of some named item.

```
[ GonearSub;
    PlayerTo(LocationOf(noun));
];
```

§**4. Purloin Command.** To PURLOIN is to acquire something without reference to any rules on accessibility.

```
[ XPurloinSub;
    if (XTestMove(noun, player)) return;
    move noun to player; give noun moved ~concealed;
    say__p = 1;
    "[Purloined.]";
];
```

§**5. Random Command.** RANDOM forces the random-number generator to a predictable seed value.

```
[ PredictableSub;
    VM_Seed_RNG(-100);
    say__p = 1;
    "[Random number generator now predictable.]";
];
```

§**6. Relations Command.** RELATIONS lists the current state of the mutable relations.

```
[ ShowRelationsSub rc tot;
    for (rc=0:rc<{-value:NUMBER_CREATED(binary_predicate)}:rc++)
        tot = tot + Relation_ShowR(rc);
    say__p = 1;
    if (tot == 0) "No new relations have been created.";
];
```

§**7. Rules Command.** RULES changes the level of rule tracing.

```
[ RulesOnSub;
    debug_rules = 1; say__p = 1;
    "Rules tracing now switched on. Type ~rules off~ to switch it off again,
    or ~rules all~ to include even rules which do not apply.";
];
[ RulesAllSub;
    debug_rules = 2; say__p = 1;
    "Rules tracing now switched to ~all~. Type ~rules off~ to switch it off again.";
];
[ RulesOffSub;
    debug_rules = 0; say__p = 1;
    "Rules tracing now switched off. Type ~rules~ to switch it on again.";
];
```

§**8. Scenes Command.** SCENES switches scene-change tracing on or off, and also shows the current position.

```
[ ScenesOnSub;
    debug_scenes = 1;
    ShowSceneStatus(); say__p = 1;
    "(Scene monitoring now switched on. Type ~scenes off~ to switch it off again.)";
];
[ ScenesOffSub;
    debug_scenes = 0; say__p = 1;
    "(Scene monitoring now switched off. Type ~scenes~ to switch it on again.)";
];
```

§**9. Scope Command.** SCOPE prints a numbered list of all objects in scope to the player.

```
Global x_scope_count;
[ ScopeSub;
    x_scope_count = 0;
    LoopOverScope(Print_ScL, noun);
    if (x_scope_count == 0) "Nothing is in scope.";
];
[ Print_ScL obj; print_ret ++x_scope_count, ": ", (a) obj, " (", obj, ")"; ];
```

§**10. Showheap Command.** SHOWHEAP is for debugging the memory heap, and is intended for Inform maintainers rather than users.

```
[ ShowHeapSub;
    DebugHeap();
];
```

§**11. ShowMe Command.** SHOWME is probably the most useful testing command: it shows the state of the current room, or a named item.

```
[ ShowMeSub view na;
    view = noun;
    if (noun == nothing) noun = real_location;
    if (ShowMeRecursively(noun, 0, (noun == real_location))) {
        if (noun == real_location)
            print "* denotes things which are not in scope^";
    }
    if (view ofclass K2_thing) {
        print "location:"; ShowRLocation(noun, true); print "^";
    }
    {-call:add_showme_details}
];
[ ShowRLocation obj top;
    if (obj ofclass K1_room) return;
    print " ";
    if (parent(obj)) {
        if (obj has worn) print "worn by ";
        else {
```

```
            if (parent(obj) has animate) print "carried by ";
            if (parent(obj) has container) print "in ";
            if (parent(obj) ofclass K1_room) print "in ";
            if (parent(obj) has supporter) print "on ";
        }
        print (the) parent(obj);
        ShowRLocation(parent(obj));
    } else {
        if (obj.component_parent) {
            if (top == false) print ", which is ";
            print "part of ", (the) obj.component_parent;
            ShowRLocation(obj.component_parent);
        }
        else print "out of play";
    }
];
[ ShowMeRecursively obj depth f c i k;
    spaces(2*depth);
    if (f && (depth > 0) && (TestScope(obj, player) == false)) { print "*"; c = true; }
    print (name) obj;
    if (depth > 0) {
        if (obj.component_parent) print " (part of ", (name) obj.component_parent, ")";
        if (obj has worn) print " (worn)";
    }
    if (obj provides IK_0) {
        k = KindHierarchy-->((obj.IK_0)*2);
        if ((k ~= K2_thing) || (depth==0)) {
            print " - ";
            if (k == K4_door or K5_container) {
                if (obj has transparent) print "transparent ";
                if (obj has locked) print "locked ";
                else if (obj has open) print "open ";
                else print "closed ";
            }
            print (I7_Kind_Name) k;
        }
    }
    print "^";
    if (obj.component_child) c = c | ShowMeRecursively(obj.component_child, depth+2, f);
    if ((depth>0) && (obj.component_sibling))
        c = c | ShowMeRecursively(obj.component_sibling, depth, f);
    if (child(obj)) c = c | ShowMeRecursively(child(obj), depth+2, f);
    if ((depth>0) && (sibling(obj))) c = c | ShowMeRecursively(sibling(obj), depth, f);
    return c;
];
```

§**12. Showverb Command.** SHOWVERB is a holdover from old I6 days, but still quite useful. It writes out the I6 command verb grammar for the supplied command.

```
[ ShowVerbSub address lines meta i;
    if (noun == 0 || ((noun->#dict_par1) & 1) == 0)
        "Try typing ~showverb~ and then the name of a verb.";
    meta = ((noun->#dict_par1) & 2)/2;
    i = DictionaryWordToVerbNum(noun);
    address = VM_CommandTableAddress(i);
    lines = address->0;
    address++;
    print "Verb ";
    if (meta) print "meta ";
    VM_PrintCommandWords(i);
    new_line;
    if (lines == 0) "has no grammar lines.";
    for (: lines>0 : lines--) {
        address = UnpackGrammarLine(address);
        print "    "; DebugGrammarLine(); new_line;
    }
];
[ DebugGrammarLine pcount;
    print " * ";
    for (: line_token-->pcount ~= ENDIT_TOKEN : pcount++) {
        if ((line_token-->pcount)->0 & $10) print "/ ";
        print (DebugToken) line_token-->pcount, " ";
    }
    print "-> ", (DebugAction) action_to_be;
    if (action_reversed) print " reverse";
];
[ DebugToken token;
    AnalyseToken(token);
    switch (found_ttype) {
    ILLEGAL_TT:
        print "<illegal token number ", token, ">";
    ELEMENTARY_TT:
        switch (found_tdata) {
        NOUN_TOKEN:           print "noun";
        HELD_TOKEN:           print "held";
        MULTI_TOKEN:          print "multi";
        MULTIHELD_TOKEN:      print "multiheld";
        MULTIEXCEPT_TOKEN:    print "multiexcept";

    GPR_TT:
        print "Routine(", found_tdata, ")";
    }
];
```

§**13. Test Command.** TEST runs a short script of commands from the source text.

```
#Iftrue ({-value:NUMBER_CREATED(test_scenario)} > 0);
[ TestScriptSub;
    switch(special_word) {
{-call:compile_test_switch}
    default:
        print ">--> The following tests are available:^";
{-call:compile_test_printout}
    }
];
Constant TEST_STACK_SIZE = 40;
Array test_stack --> TEST_STACK_SIZE;
Global test_sp = 0;
[ TestStart T R l k;
    if (test_sp >= TEST_STACK_SIZE) ">--> Testing too many levels deep";
    test_stack-->test_sp = T;
    test_stack-->(test_sp+1) = 0;
    test_stack-->(test_sp+3) = l;
    test_sp = test_sp + 4;
    if ((R-->0) && (R-->0 ~= real_location)) {
        print "(first moving to ", (name) R-->0, ")^";
        PlayerTo(R-->0, 1);
    }
    k=1;
    while (R-->k) {
        if (R-->k notin player) {
            print "(first acquiring ", (the) R-->k, ")^";
            move R-->k to player;
        }
        k++;
    }
    print "(Testing.)^"; say__p = 1;
];
[ TestKeyboardPrimitive a_buffer a_table p i j l spaced ch;
    if (test_sp == 0) {
        test_stack-->2 = 1;
        return VM_ReadKeyboard(a_buffer, a_table);
    }
    else {
        p = test_stack-->(test_sp-4);
        i = test_stack-->(test_sp-3);
        l = test_stack-->(test_sp-1);
```

```
        print "[";
        print test_stack-->2;
        print "] ";
        test_stack-->2 = test_stack-->2 + 1;
        style bold;
        while ((i < l) && (p->i ~= '/')) {
            ch = p->i;
            if (spaced || (ch ~= ' ')) {
                if ((p->i == '[') && (p->(i+1) == '/') && (p->(i+2) == ']')) {
                    ch = '/'; i = i+2;
                }
                a_buffer->(j+WORDSIZE) = ch;
                print (char) ch;
                i++; j++;
                spaced = true;
            } else i++;
        }
        style roman;
        print "^";
        #ifdef TARGET_ZCODE;
        a_buffer->1 = j;
        #ifnot; ! TARGET_GLULX
        a_buffer-->0 = j;
        #endif;
        VM_Tokenise(a_buffer, a_table);
        if (p->i == '/') i++;
        if (i >= l) {
            test_sp = test_sp - 4;
        } else test_stack-->(test_sp-3) = i;
    }
];
#IFNOT;
[ TestScriptSub;
    ">--> No test scripts exist for this game.";
];
#ENDIF;
```

§**14. Trace Command.** Another holdover from I6: TRACE sets the level of parser tracing, on a scale of 0 (off, the default) to 5.

```
[ TraceOnSub; parser_trace=1; say__p = 1; "[Trace on.]"; ];
[ TraceLevelSub;
    parser_trace = noun; say__p = 1;
    print "[Parser tracing set to level ", parser_trace, ".]^";
];
[ TraceOffSub; parser_trace=0; say__p = 1; "Trace off."; ];
```

§**15. Tree Command.** TREE prints out the I6 object tree, though this is not always very helpful in I7 terms. It should arguably be withdrawn, but doesn't seem to do any harm.

```
[ XTreeSub i;
    if (noun == 0) {
        objectloop (i)
            if (i ofclass Object && parent(i) == 0) XObj(i);
    }
    else XObj(noun,1);
];
[ XObj obj f;
    if (parent(obj) == 0) print (name) obj; else print (a) obj;
    print " (", obj, ") ";
    if (f == 1 && parent(obj) ~= 0)
        print "(in ", (name) parent(obj), " ", parent(obj), ")";
    new_line;
    if (child(obj) == 0) rtrue;
    if (obj == Class)
        WriteListFrom(child(obj), NEWLINE_BIT+INDENT_BIT+ALWAYS_BIT+NOARTICLE_BIT, 1);
    else
        WriteListFrom(child(obj), NEWLINE_BIT+INDENT_BIT+ALWAYS_BIT+FULLINV_BIT, 1);
];
```

§**16. Grammar.** In the old I6 parser, testing commands had their own scope hardwired in to the code: this worked by comparing the verb command word directly against `'scope'` and the like. That would go wrong if the testing commands were translated into other languages, and was a crude design at best. The following scope token is better: using this token instead of `multi` provides a noun with universal scope (but restricted to I7 objects, so I6 pseudo-objects like `compass` are not picked up) and able to accept multiple objects.

```
[ testcommandnoun obj o2;
    switch (scope_stage) {
        1: rtrue; ! allow multiple objects
        2: objectloop (obj)
            if ((obj ofclass Object) && (obj provides IK_0))
                PlaceInScope(obj, true);
        3: print "There seems to be no such object anywhere in the model world.^";
    }
];
{-testing-command:abstract}
    * scope=testcommandnoun 'to' scope=testcommandnoun -> XAbstract;
{-testing-command:actions}
    *                                       -> ActionsOn
    * 'on'                                  -> ActionsOn
    * 'off'                                 -> ActionsOff;
{-testing-command:gonear}

§**9. Commands.** `LanguageVerbLikesAdverb` is called by `PrintCommand` when printing an `UPTO_PE` error or an inference message. Words which are intransitive verbs, i.e., which require a direction name as an adverb ("walk west"), not a noun ("I only understood you as far as wanting to touch the ground"), should cause the routine to return `true`.

`LanguageVerbMayBeName` is called by `NounDomain` when dealing with the player's reply to a "Which do you mean, the short stick or the long stick?" prompt from the parser. If the reply is another verb (for example, LOOK) then then previous ambiguous command is discarded unless it is one of these words which could be both a verb and an adjective in a `name` property.

```
[ LanguageVerb i;
    switch (i) {
    'i//','inv','inventory':
            print "take inventory";
    'l//':   print "look";

§**13. Printing Mechanism.** The following routine produces a "library message" – though the library is no more, the terminology lives on.

The `L__M` routine is designed to reach up into I7 to offer it a chance to intervene, but then go back to the I6 method if it doesn't. The Standard Rules ordinarily define these three routines as stubs which always return false, so by default there's no intervention. (This is the hook for the new model of library messages which will be introduced in future builds.)

We divide into three cases because `##Miscellany` and `##ListMiscellany` are fake actions, not actions, in I6. This means it would not be type-safe to store them in I7 variables whose kind of value is "action-name", and that would make any single I7 routine handling all three kinds of message quite difficult to write.

```
[ L__M act n x1 x2 rv flag;
    @push sw__var;
    sw__var = act;
    if (n == 0) n = 1;
    @push action;
    lm_act = act;
    lm_n = n;
    lm_o = x1;
    lm_o2 = x2;
    switch (act) {
        ##Miscellany: rv = (+ whether or not intervened in miscellaneous message +);
        ##ListMiscellany: rv = (+ whether or not intervened in miscellaneous list message +);
        default: rv = (+ whether or not intervened in action message +);
    }
    action = sw__var;
    if (rv == false) rv = RunRoutines(LibraryMessages, before);
    @pull action;
    if (rv == false) LanguageLM(n, x1, x2);
    @pull sw__var;
];
```

MStack Template B/stackt

Purpose

To allocate space on the memory stack for frames of variables to be used by rulebooks, activities and actions.

---

§**1. The Memory Stack.** The M-Stack, or memory stack, is a sequence of frames, piled upwards. If we had an accessible stack in memory, we could use that, but neither the Z-machine nor Glulx has such a stack, alas, alas, alas. The following is not a very good solution, but it just about works.

```
Constant MAX_MSTACK_FRAME = 2 + {-value:max_frame_size_needed};
Constant MSTACK_CAPACITY = 20;
Constant MSTACK_SIZE = MSTACK_CAPACITY*MAX_MSTACK_FRAME;
Array MStack --> MSTACK_SIZE;
Global MStack_Top = 0; ! Topmost word currently used
```

§**2. Create Frame.** A frame is created by calling the following function with two arguments: `creator`, a function which initialises a block of variables, and an ID number identifying the owner.

The `creator` function is called with the address at which to initialise the variables as its first argument, and the value 1 as the second argument. (The idea is that the same function can be used later to deallocate the variables, and then the second argument will be -1.) The `creator` function returns the extent of the block of memory it has used, in words. Thus is required to be strictly less than `MAX_MSTACK_FRAME` minus 1.

```
[ Mstack_Create_Frame creator id extent;
    if (creator == 0) rfalse;
    extent = creator.call(MStack_Top+2, 1);
    if (extent == 0) rfalse;
    if (MStack_Top + MAX_MSTACK_FRAME >= MSTACK_SIZE + 2) {
        RunTimeProblem(RTP_MSTACKMEMORY, MSTACK_SIZE);
        Mstack_Backtrace();
        rfalse;
    }
    MStack_Top++;
    MStack-->MStack_Top = id;
    MStack_Top++;
    MStack_Top = MStack_Top + extent;
    MStack-->MStack_Top = -(extent+2);
    rtrue;
];
```

§**3. Destroy Frame.** As sketched above, the same creator function and ID number are passed to the following routine to destroy the frame again. It takes the stack down to the level of the most recently created frame with this ID number: note that each action, for instance, has its own ID number for this purpose, but can be taking place several times in a nested fashion – one taking action might have caused another taking action which caused a third, for instance, so that there are three incomplete taking actions at once. In that case, there will be three independent sets of taking action variables on the M-stack, all with the same ID number. We remove the topmost one: the implication of that is that frames must always be destroyed in reverse order of creation.

In practice, I7 uses frames such that the frame sought should always be the topmost one in any case, and so that frames are always explicitly destroyed, not wiped by being undercut when an earlier-created frame is destroyed.

```
[ Mstack_Destroy_Frame creator id pos;
    pos = Mstack_Seek_Frame(id);
    if (pos == 0) rfalse; ! Not found: do nothing
    MStack_Top = pos - 2; ! Clear mstack down to just below this frame
    if (creator) creator.call(pos, -1);
    rtrue;
];
```

§**4. Seek Frame.** We return the position on the M-stack of the most recently created frame with the given ID number (see above), or 0 if no such frame exists; the size is stored in the global variable `MStack_Frame_Extent`. (Because word 0 on the stack is used as a sentinel – all frames are placed above it – no frame can actually begin at word 0 on the stack, so 0 is safe to use as an exception.)

```
Global MStack_Frame_Extent = 0;

[ Mstack_Seek_Frame id pos;
    pos = MStack_Top;
    while (MStack-->pos ~= 0) {
        MStack_Frame_Extent = MStack-->pos;
        pos = pos + MStack_Frame_Extent;
        MStack_Frame_Extent = (-2) - MStack_Frame_Extent;
        if (MStack-->(pos+1) == id) return pos+2;
    }
    MStack_Frame_Extent = 0;
    return 0; ! Not found
];
```

§**5. Backtrace.** Purely for debugging purposes, and giving feedback if the stack runs out of memory:

```
[ Mstack_Backtrace pos k;
    print "Mstack backtrace: size ", MStack_Top+1, " words^";
    pos = MStack_Top;
    while (MStack-->pos ~= 0) {
        MStack_Frame_Extent = MStack-->pos;
        pos = pos + MStack_Frame_Extent;
        MStack_Frame_Extent = (-2) - MStack_Frame_Extent;
        print "Block at ", pos+2,
            " owner ID ", MStack-->(pos+1), " size ", MStack_Frame_Extent, "^";
        for (k=0: k<MStack_Frame_Extent: k++) print MStack-->(pos+2+k), " ";
        print "^";
    }
];
```

§**6. Access to Variables.** An M-stack variable is identified by a combination of ID number and offset: for instance ID 20007, offset 1, is the variable "room gone to" belonging to the going action. The following routine converts that into an address on the M-stack, in the topmost block with the given ID number (since "room gone to", for instance, always means its value in the most current going action of those now under way). Typechecking in the compiler should mean that it is impossible to produce either error message below: NI will only compile valid uses of `MstVO` ("M-stack variable offset") where the seek succeeds and the offset is within range.

```
[ MstVO id off pos;
    pos = Mstack_Seek_Frame(id);
    if (pos == 0) {
        print "Variable unavailable: ", id, "/", off, "^";
        rfalse;
    }
    if ((off<0) || (off >= MStack_Frame_Extent)) {
        print "Variable stack offset wrong: ", id, "/", off, " at ", pos, "^";
        rfalse;
    }
    return pos+off;
];
```

§**7. Access to Nonexistent Variables.** A long-standing point where I7 is not as strict in type-checking as it might be occurs when checking rule preambles like "Before going to a dead end...". Such a preamble must be checked whatever the current action is – in many cases, it will not be a going action at all; which means that "room gone to", a value implied by the "to" clause, will not exist. If the type-checking were stricter, it would be a nuisance for authors, and instead we relax a little by accessing such variables using a more forgiving routine. Here, if a variable does not exist, we return 0 to mean that it can be read at M-stack position 0: this is the sentinel word, which is not part of any frame, and which contains 0. Thus the variable reads as if it is 0, the default for the kind of value "object", which is the KOV for action variables such as "room gone to".

The routine may only be used where the variable is being read, and never where it is to be written, of course: that would corrupt the sentinel.

```
[ MstVON id off pos;
    pos = Mstack_Seek_Frame(id);
    if (pos == 0) {
        return 0; ! word position 0 on the M-stack
    }
    if ((off<0) || (off >= MStack_Frame_Extent)) {
        print "Variable stack offset wrong: ", id, "/", off, " at ", pos, "^";
        rfalse;
    }
    return pos+off;
];
```

§**8. Rulebook Variables.** Each rulebook has a slate of variables, usually empty, with ID number the same as the rulebook's own ID number. (Rulebook IDs number upwards from 0 in order of creation in the source text.) The associated creator functions, usually null, are stored in an array.

```
{-array:rulebook_var_creators}
[ MStack_CreateRBVars rb cr;
    cr = rulebook_var_creators-->rb;
    if (cr == 0) return;
    Mstack_Create_Frame(cr, rb);
];
[ MStack_DestroyRBVars rb cr;
    cr = rulebook_var_creators-->rb;
    if (cr == 0) return;
    Mstack_Destroy_Frame(cr, rb);
];
```

§**9. Activity Variables.** Exactly the same goes for activity variables except that here the ID number is $10000 + N$, where N is the allocation ID of the activity. (This would fail if there were more than 10,000 rulebooks, but this is very difficult to see happening.)

```
{-array:activity_var_creators}
[ MStack_CreateAVVars av cr;
    cr = activity_var_creators-->av;
    if (cr == 0) return;
    Mstack_Create_Frame(cr, av + 10000);
];
[ MStack_DestroyAVVars av cr;
    cr = activity_var_creators-->av;
    if (cr == 0) return;
    Mstack_Destroy_Frame(cr, av + 10000);
];
```

Chronology Template B/chrt

Purpose

To record information now which will be needed later, when a condition phrased in the perfect tense is tested.

---

§**1. Scheme I.** If source text contains a condition like "if the well has been dry, ...", then we need to keep a chronological record by testing at every turn whether or not the well is dry: we log whether this is true now, whether it has ever been true, for how many consecutive turns it has been true (to a maximum of 127), and how many times it has become true having just been false (again, to a maximum of 127 times). All this information is packed into a single word, arranged as a 15-bit bitmap: the least significant bit is the state of the condition now (true or false), the next 7 bits are the number of false-to-true "trips" observed over time, and the top 7 bits are the number of consecutive turns on which the condition has been true ("consecutives"). The 16th and most significant bit is unused, so that the state is always positive even in a 16-bit virtual machine – a convenience since we then don't need to worry about the effect of signed division and remainder on the bitmap.

There is no need to store a flag for "has this condition ever been true", because this is equivalent the number of trips being greater than zero. This might look wrong for a condition which is true at start of play – say, if the well was always dry – because then its state has never changed from false to true. But in fact when the VM starts up the state word is initially always 0: it's only when the startup rulebook fires the update chronological records rule (see below) that we first test whether the well is dry, and that forces a trip from false to true if the well is dry at start of play. Therefore, if T is the number of trips for the condition then $T = 0$ if and only if the condition has been false from the very start of play. If the condition is true now, then $T = 1$ if and only if it has always been so.

§**2. Present and Past.** Each individual condition has its own unique "PT number", counting upwards from 0 in order of compilation by NI, and a "chronological record" is a word array with a state word as described above for each PT number.

However, we keep not one but two chronological records: one for the situation now, called the "present chronological record", and one for the situation as it was just before interesting things most recently happened, called the "past chronological record". If one of those interesting things was that the well ran dry, then in our example the state word for the condition "if the well has been dry" would be different in the two chronological records. We keep two records in order to be able to detect conditions in four different tenses:

(1) Present tense ("if the well is dry"): none of this machinery is used, because we can just test directly instead, so a present tense condition has no PT-number.
(2) Past tense ("if the well was dry"): we look at the flag bit in the past chronological record.
(3) Perfect tense ("if the well has been dry"): we look at whether or not $T > 0$ in the present chronological record.
(4) Past perfect tense ("if the well had been dry"): we look at whether or not $T > 0$ in the past chronological record.

It's a somewhat ambiguous matter of context in English when the reference time is for past tenses. If somebody comes out into the sunshine and says, "But it was raining," when does he mean? We would reasonably guess earlier that day, and probably only an hour or two ago, but that's a contextual judgement made on the basis of our own experience of how rapidly weather changes. The context for Inform source text is always that of actions, so our convention is that the reference time for past tenses is the point just before the current action began. Such key moments – when things are just about to happen – are called "chronology points". There is a CP just before each action begins; there is a CP in the startup process; and there is a

CP at the end of each turn, for good measure. CPs happen when somebody calls `ChronologyPoint()`. The action machinery does this directly, while the startup CP and the CP at end of turn happen in the course of the update chronological records rule (below).

§**3. Chronology Point.** This is when the time of reference for past tenses is now: so it is where the past becomes the present. Soon, exciting things will happen, and the present will go on developing, while the past will remain as it was; until things calm down again and we come to another chronology point.

```
[ ChronologyPoint pt;
    for (pt=0:pt<NO_PAST_TENSE_CONDS:pt++)
        past_chronological_record-->pt = present_chronological_record-->pt;
];
```

§**4. Update Chronological Records Rule.** It might seem odd that a routine to, supposedly, update something would only call another routine called `TestSinglePastState`: but in this setting, any test updates the state, because it changes the number of times something has been found true, and so on.

```
[ UPDATE_CHRONOLOGICAL_RECORDS_R pt;
    for (pt=0: pt<NO_PAST_TENSE_CONDS: pt++) TestSinglePastState(false, pt, true, -1);
    ChronologyPoint();
    rfalse;
];
```

§**5. Test Single Past State.** `TestSinglePastState` is called with four arguments:

(a) `past_flag` is true if we want to test a condition like "if the well was dry" or "if the well had been dry", which concern only the state as it was at the last chronology point – in other words, the `past_chronological_record`, which we must not change; whereas `past_flag` is false if we want to test a present tense like "if the well is dry" or "if the well has been dry", because then we deal with the `present_chronological_record` which must be kept continuously updated.

(b) `pt` is the PT number for the condition.

(c) `turn_end` is true if we are making the test at the end of a turn, as part of the update chronological records rule, and false otherwise. (For these purposes the start of play is a turn end since the UCRR runs then, too.)

(d) `wanted` describes what information the function should return, as detailed in its code below.

```
[ TestSinglePastState past_flag pt turn_end wanted
    old new trips consecutives ct_0 ct_1;
    if (past_flag) {
        new = (past_chronological_record-->pt) & 1;
        trips = ((past_chronological_record-->pt) & $$11111110)/2;
        consecutives = ((past_chronological_record-->pt) & $$111111100000000)/256;
    } else {
        old = (present_chronological_record-->pt) & 1;
        trips = ((present_chronological_record-->pt) & $$11111110)/2;
        consecutives = ((present_chronological_record-->pt) & $$111111100000000)/256;
        switch(pt) {
! Test cases for conditions by PT number: each sets "new" to whether it is true or false now
{-call:past_tenses_i6_escape}
        }
        if (new == false) {
            consecutives = 0;
```

```
        } else {
            if (old == false) { trips++; if (trips > 127) trips = 127; }
            if (turn_end) { consecutives++; if (consecutives > 127) consecutives = 127; }
        }
        ! print pt,":o=",old," n=",new," t=",trips," c=",consecutives,"^";
        present_chronological_record-->pt = new + 2*trips + 256*consecutives;
    }
    switch(wanted) {
        0: if (new) return new;
        1: if (new) return trips;
        2: if (new) return consecutives;
        4: return new;
        5: return trips;
        6: return consecutives;
    }
    return 0;
];
```

§**6. Scheme II.** Actions discussed in the past tense – "if we have taken the ball" or, more subtly, "Instead of waiting for the third turn" (which also refers to the past) – are handled in a related but simpler way. NI counts such references, just as with other past tense conditions above, but this time stores a state in two simple word arrays: `TimesActionHasHappened` and `TurnsActionHasBeenHappening`.

It might reasonably be asked why we don't simply use all of the clever machinery above: why have an entirely different system here? One reason is that actions are events and not continuous states of being. "The well is dry" could be true for any extent of time, but "taking the ball" either happens at a given moment or doesn't: it is not continuously true. We are therefore in the business of counting events, not measuring durations. Another reason is that the point of reference for past tenses is different. It makes no sense to say "if we were looking" because that would mean at a time just before the current action, when actions were probably not happening at all; while "if we had looked" and "if we have looked" would almost always be identical in meaning for the same reason. So we need a much simpler system with just one possible past tense; we don't need to keep two different states; and we use the extra storage to enable us to count the number of times, and the number of turns, to at least 31767 instead of stopping at 127. (We also generate more legible code to test past tense actions.)

§**7. Past Action Routines.** Actions can be quite complicated to test even in the present, and this is much more conveniently done in a routine with its own NI-generated stack frame; so each past tense action has its own testing routine, with a name like `PAPR_41`, which returns true or false depending on whether the action is going on now. The word array `PastActionsI6Routines` then contains a null-terminated list of these routines.

```
{-call:past_actions_i6_routines}
```

§**8. Track Actions.** The routine `TrackActions` then updates the two arrays, and is the equivalent for past tense actions of `ChronologyPoint`. It's called twice for each action: `TrackActions(false)` just as a new action is about to begin, and then `TrackActions(true)` just after it has finished – note in particular that if action B happens in the middle of action A, for instance because of a try phrase, then the `TrackActions(true)` call for B happens when A is back as the current action. In fact, that's the point: because it tells us that B was not the main action for the turn, but only a phase which has now passed again.

For each of the action patterns we track, we need to count the number of times such an action has been tried (*not* the number of times it succeeded), and also the number of consecutive turns on which it has been "the" action. The count of the number of tries is unambiguous and easy to keep: it is incremented at the start-of-action call only, and only if the action matches. But the consecutive turn count is more problematic. The user wants to think of actions and turns as synonymous, and to write conditions like "Before going for the third turn", and we want to play along because that's a natural phrasing: but actions and turns are not synonymous at all. The rules are therefore:

(1) At the start-of-action call, provided the action is not a silent one, the consecutive turns count is either incremented or zeroed, depending on whether the action matches. Silent actions are ignored because they are almost always knock-on actions tried in the course of other actions, and are certainly not the "main" action of the turn. But the count can be incremented only once in the course of each turn, so that "Instead of taking something for the third turn: ..." cannot happen on the very first turn because TAKE ALL causes three or more take actions.
(2) At the readjustment call, provided the action is not a silent one, the consecutive turns count is zeroed if the action does not match.

Why do we zero the count in rule (2)? Well, suppose that the player types OPEN BOX, so that the opening action takes place, and that it causes a further (non-silent) action, say examining the lid: and suppose that the action pattern we track the turn count for is "examining something". Then the following calls take place:

(a) `TrackActions(false)` while the action is "opening the box". Turn count zeroed by rule (1).
(b) `TrackActions(false)` while the action is "examining the lid". Turn count incremented by rule (1).
(c) `TrackActions(true)` while the action is "opening the box". Turn count zeroed by rule (2).
(d) `TrackActions(true)` while the action is "opening the box". Turn count zeroed by rule (2).

Thus rule (2) prevents us from counting this turn as the first of a sequence of turns in which examining something was the action, because it wasn't the main action of the turn.

A further complication is that we need to record the qualification, or not, even of silent actions, because testing rules like

> Instead of taking the top hat less than three times...

works by checking that (a) we are currently taking the top hat, and (b) have done so fewer than three times before. (b) uses the turn count described above; but (a) cannot simply look to see if that count is positive, since the action might be happening silently and thus not have contributed to the count; so we also record a flag to hold whether the action seems to be happening in this turn, silent or not.

```
[ TrackActions readjust ct_0 ct_1 i;
    for (i=0: PastActionsI6Routines-->i: i++) {
        if ((PastActionsI6Routines-->i).call()) {
            ! Yes, the current action matches action pattern i:
            if (readjust) continue;
            (TimesActionHasHappened-->i)++;
            if (LastTurnActionHappenedOn-->i ~= turns + 5) {
                LastTurnActionHappenedOn-->i = turns + 5;
                ActionCurrentlyHappeningFlag->i = 1;
                if (keep_silent == false)
                    (TurnsActionHasBeenHappening-->i)++;
            }
        } else {
```

```
            ! No, the current action doesn't match action pattern i:
            if (keep_silent == false) { TurnsActionHasBeenHappening-->i = 0; }
            if (LastTurnActionHappenedOn-->i ~= turns + 5)
                ActionCurrentlyHappeningFlag->i = 0;
        }
    }
];
```

§**9. Storage.** The necessary array allocation.

```
{-call:chronology_extents_i6_escape}
Array TimesActionHasHappened-->(NO_PAST_TENSE_ACTIONS+1);
Array TurnsActionHasBeenHappening-->(NO_PAST_TENSE_ACTIONS+1);
Array LastTurnActionHappenedOn-->(NO_PAST_TENSE_ACTIONS+1);
Array ActionCurrentlyHappeningFlag->(NO_PAST_TENSE_ACTIONS+1);
Array past_chronological_record-->(NO_PAST_TENSE_CONDS+1);
Array present_chronological_record-->(NO_PAST_TENSE_CONDS+1);
```

Printing Template B/print

Purpose

To manage the line skips which space paragraphs out, and to handle the printing of names of objects, pieces of text and numbers.

---

§**1. Paragraph Control.** Ah, yes: the paragraph breaking algorithm. In *TEX: The Program*, Donald Knuth writes at §768: "It's sort of a miracle whenever `\halign` and `\valign` work, because they cut across so many of the control structures of TEX." It's sort of a miracle whenever Inform 7's paragraph breaking system works, too. Most users probably imagine that it's implemented by having I7 look at where the cursor currently is (at the start of a line or not) and whether a line has just been skipped. In fact, the virtual machines simply do not offer facilities like that, and so we have to use our own book-keeping. Given the huge number of ways in which text can be printed, this is a delicate business. For some years now, "spacing bugs" – those where a spurious extra skipped line appears in a paragraph break, or where, conversely, no line is skipped at all – have been the least welcome in the Inform bugs database.

The basic method is to set `say__p`, the paragraph flag, when we print any matter; every so often we reach a "divide paragraph" point – for instance when one rule has finished and before another is about to start – and at those positions we look for `say__p`, and print a skipped line (and clear `say__p` again) if we find it. Thus:

```
> WAIT
The clock ticks ominously. ...first rule
    ...skipped line printed at a Divide Paragraph point
Mme Tourmalet rises from her chair and slips out. second rule
    ...skipped line printed at a Divide Paragraph point
>
```

A divide paragraph point occurs between any two rules in an action rulebook, but not an activity rulebook: many activities exist to print text, such as the names of objects, and there would be wild spacing accidents if paragraphs were divided there. Inform places DPPs elsewhere, too: and the text substitution "[conditional paragraph break]" allows the user to place one anywhere.

A traditional layout convention handed down from Infocom makes an exception of the first paragraph to appear after the prompt, but only in one situation. Ordinarily, the first paragraph of any turn appears straight after the prompt:

```
> EXAMINE DOG
Mme Tourmalet's borzoi looks as if it means fashion, not business.
```

The command is echoed on screen as the player types, but this doesn't set the paragraph flag, which is still clear when the text "Mme Tourmalet's..." begins to be printed. The single exception occurs when the command calls for the player to go to a new location, when a skipped line is printed before the room description for the new room. Thus:

```
> SOUTH
    ...the "going look break"
Rocky Beach
```

(Note that this is not inherent in the looking action:

```
> LOOK
Rocky Beach
```

...which obeys the standard paragraphing conventions.)

So much for automatic paragraph breaks. However, we need a variety of different ways explicitly to control paragraphs, in order to accommodate traditional layout conventions handed down from Infocom.

The simplest exceptional kind of paragraph break is a "command clarification break", in which a single new-line is printed but there is no skipped line: as the name implies, it's traditionally used when a command such as OPEN DOOR is clarified. For example:

```
(first unlocking the oak door) ...now a command clarification break
You open the oak door.
```

This is not quite the same thing as a "run paragraph on" break, in which we also deliberately suppress the skipped line, but make an exception for the skipped line which ought to appear last before the prompt: the idea is to merge two or more paragraphs together.

```
> TAKE ALL
marmot: Taken. ...we run paragraph on here
weasel: Taken. ...and also here
     ...despite which the final skip does occur
>  ...before the next prompt
```

A more complicated case is "special look spacing", used for the break which occurs after the (boldface) short name of a room description is printed. This is tricky because it is sometimes followed directly by a long description, and we don't want a skipped line:

```
Villa Christiane ...a special look spacing break
The walled garden of a villa in Cap d'Agde.
     ...a Divide Paragraph break
Mme Tourmalet's borzoi lazes in the long grass.
```

But sometimes it is followed directly by a subsequent paragraph, and again we want no skip:

```
Villa Christiane ...a special look spacing break
Mme Tourmalet's borzoi lazes in the long grass.
```

And sometimes it is the only content of the room description and is followed only by the prompt:

```
Villa Christiane ...a special look spacing break
     ...a break inserted before the prompt
>
```

To recap, we have five kinds of paragraph break:

(a) Standard breaks at "divide paragraph points", used between rules.
(b) The "going look break", used before the room description after going to a new room.
(c) A "command clarification break", used after text clarifying a command.
(d) A "run paragraph on" break, used to merge multiple paragraphs into a single block of text.
(e) The "special look spacing" break, used after the boldface headline of a room description.

We now have to implement all of these behaviours. The code, while very simple, is highly prone to behaving unexpectedly if changes are made, simply because of the huge number of circumstances in which paragraphs are printed: so change nothing without very careful testing.

§**2. State.** The current state is stored in a combination of two global variables:

(1) `say__p`, the "say paragraph" flag, which is set if a paragraph break needs to be printed before the next text can begin;

(2) `say__pc`, originally named as the "paragraph completed" flag, but which is now a bitmap:

(2a) `PARA_COMPLETED` is set if a standard paragraph break has been made since the last time the flag was cleared;

(2b) `PARA_PROMPTSKIP` is set to indicate that the current printing position does not follow a skipped line, and that further material is expected which will run on from the previous paragraph, but that if no further material turns up then a skipped line would be needed before the next prompt;

(2c) `PARA_SUPPRESSPROMPTSKIP` is set to indicate that, despite `PARA_PROMPTSKIP` being set, no skipped line is needed before the prompt after all;

(2d) `PARA_NORULEBOOKBREAKS` suppresses divide paragraph points in between rules in rulebooks; it treats all rulebooks, and in particular action rulebooks, the way activity rulebooks are treated. (The flag is used for short periods only and never across turn boundaries, prompts and so on.)

(2e) `PARA_CONTENTEXPECTED` is set after a paragraph division as a signal that if any contents looks likely to be printed soon then `say__p` needs to be set, because a successor paragraph will then have started. This is checked by calling `ParaContent()` – while it's slow to have to call this routine so often, that's better than compiling inline code with the same effect, because minimising compiled code size is more important, and speed is never a big deal when printing.

Not all printing is to the screen: sometimes the output is to a file, or to memory, and in that case we want to start the switched output at a clear paragraphing state and then go back to the screen afterwards without any sign of change. The correct way to do this is to push the `say__p` and `say__pc` variables onto the VM stack and call `ClearParagraphing()` before starting to print to the new stream, and then pull the variables back again before resuming printing to the old stream.

In no other case should any code alter `say__pc` except via the routines below.

```
!Constant TRACE_I7_SPACING;

[ ClearParagraphing;
    say__p = 0; say__pc = 0;
];

[ DivideParagraphPoint;
    #ifdef TRACE_I7_SPACING; print "[DPP", say__p, say__pc, "]"; #endif;
    if (say__p) {
        new_line; say__p = 0; say__pc = say__pc | PARA_COMPLETED;
        if (say__pc & PARA_PROMPTSKIP) say__pc = say__pc - PARA_PROMPTSKIP;
        if (say__pc & PARA_SUPPRESSPROMPTSKIP) say__pc = say__pc - PARA_SUPPRESSPROMPTSKIP;
    }
    #ifdef TRACE_I7_SPACING; print "[-->", say__p, say__pc, "]"; #endif;
    say__pc = say__pc | PARA_CONTENTEXPECTED;
];

[ ParaContent;
    if (say__pc & PARA_CONTENTEXPECTED) {
        say__pc = say__pc - PARA_CONTENTEXPECTED;
        say__p = 1;
    }
];

[ GoingLookBreak;
    if (say__pc & PARA_COMPLETED == 0) new_line;
    ClearParagraphing();
];

[ CommandClarificationBreak;
```

```
    new_line;
    ClearParagraphing();
];
[ RunParagraphOn;
    #ifdef TRACE_I7_SPACING; print "[RPO", say__p, say__pc, "]"; #endif;
    say__p = 0;
    say__pc = say__pc | PARA_PROMPTSKIP;
    say__pc = say__pc | PARA_SUPPRESSPROMPTSKIP;
];
[ SpecialLookSpacingBreak;
    #ifdef TRACE_I7_SPACING; print "[SLS", say__p, say__pc, "]"; #endif;
    say__p = 0;
    say__pc = say__pc | PARA_PROMPTSKIP;
];
[ EnsureBreakBeforePrompt;
    if ((say__p) ||
        ((say__pc & PARA_PROMPTSKIP) && ((say__pc & PARA_SUPPRESSPROMPTSKIP)==0)))
        new_line;
    ClearParagraphing();
];
[ PrintSingleParagraph matter;
    say__p = 1;
    say__pc = say__pc | PARA_NORULEBOOKBREAKS;
    PrintText(matter);
    DivideParagraphPoint();
    say__pc = 0;
];
```

§**3. Say Number.** The global variable `say__n` is set to the numerical value of any quantity printed, and this is used for the text substitution "[s]", so that "You have been awake for [turn count] turn[s]." will expand correctly.

```
[ STextSubstitution;
    if (say__n ~= 1) print "s";
];
```

§**4. Prompt.** This is the text printed just before we wait for the player's command: it prompts him to type.

```
[ PrintPrompt i;
    style roman;
    EnsureBreakBeforePrompt();
    PrintText( (+ command prompt +) );
    ClearBoxedText();
    ClearParagraphing();
    enable_rte = true;
];
```

§**5. Boxed Quotations.** These appear once only, and happen outside of the paragraphing scheme: they are normally overlaid as windows on top of the regular text. We can request one at any time, but it will appear only at prompt time, when the screen is fairly well guaranteed not to be scrolling. (Only fairly well since it's just possible that *Border Zone*-like tricks with real-time play might be going on, but whatever happens, there is at least a human-appreciable pause in which the quotation can be read before being taken away again.)

```
Global pending_boxed_quotation; ! a routine to overlay the quotation on screen
[ DisplayBoxedQuotation Q;
    pending_boxed_quotation = Q;
];
[ ClearBoxedText i;
    if (pending_boxed_quotation) {
        for (i=0: Runtime_Quotations_Displayed-->i: i++)
            if (Runtime_Quotations_Displayed-->i == pending_boxed_quotation) {
                pending_boxed_quotation = 0;
                return;
            }
        Runtime_Quotations_Displayed-->i = pending_boxed_quotation;
        ClearParagraphing();
        pending_boxed_quotation();
        ClearParagraphing();
        pending_boxed_quotation = 0;
    }
];
```

§**6. Score Notification.** This doesn't really deserve to be at I6 level at all, but since for traditional reasons we need to use conditional compilation on `NO_SCORING`, and since we want a fancy text style for Glulx, ...

```
[ NotifyTheScore;
#Ifndef NO_SCORING;
    if (notify_mode == 1) {
        DivideParagraphPoint();
        VM_Style(NOTE_VMSTY);
        print "["; L__M(##Miscellany, 50, score-last_score); print ".]^";
        VM_Style(NORMAL_VMSTY);
    }
#Endif;
];
```

§**7. Status Line.** Status line printing happens on the upper screen window, and outside of the paragraph control system.

Support for version 6 of the Z-machine is best described as grudging. It requires a heavily rewritten `DrawStatusLine` equivalent, to be found in "ZMachine.i6t".

```
#Ifdef TARGET_ZCODE;
#Iftrue (#version_number == 6);
[ DrawStatusLine; Z6_DrawStatusLine(); ];
#Endif;
#Endif;

#Ifndef DrawStatusLine;
[ DrawStatusLine width posb;
    @push say__p; @push say__pc;
    BeginActivity(CONSTRUCTING_STATUS_LINE_ACT);
    VM_StatusLineHeight(1); VM_MoveCursorInStatusLine(1, 1);
    if (statuswin_current) {
        width = VM_ScreenWidth(); posb = width-15;
        spaces width;
        ClearParagraphing();
        if (ForActivity(CONSTRUCTING_STATUS_LINE_ACT) == false) {
            VM_MoveCursorInStatusLine(1, 2);
            switch(metaclass(left_hand_status_line)) {
                String: print (string) left_hand_status_line;
                Routine: left_hand_status_line();
            }
            VM_MoveCursorInStatusLine(1, posb);
            switch(metaclass(right_hand_status_line)) {
                String: print (string) right_hand_status_line;
                Routine: right_hand_status_line();
            }
        }
        VM_MoveCursorInStatusLine(1, 1); VM_MainWindow();
    }
    ClearParagraphing();
    EndActivity(CONSTRUCTING_STATUS_LINE_ACT);
    @pull say__pc; @pull say__p;
];
#Endif;
```

§**8. Status Line Utilities.** Two convenient routines for the default values of `right_hand_status_line` and `left_hand_status_line` respectively. `SL_Location` also implements the text substitution "[player's surroundings]".

```
[ SL_Score_Moves;
    if (not_yet_in_play) return;
    #ifdef NO_SCORING; print sline2; #ifnot; print sline1, "/", sline2; #endif;
];
[ SL_Location;
    if (not_yet_in_play) return;
    if (location == thedark) {
        BeginActivity(PRINTING_NAME_OF_DARK_ROOM_ACT);
        if (ForActivity(PRINTING_NAME_OF_DARK_ROOM_ACT) == false)
            L__M(##Miscellany, 71);
        EndActivity(PRINTING_NAME_OF_DARK_ROOM_ACT);
    } else {
        FindVisibilityLevels();
        if (visibility_ceiling == location) print (name) location;
        else print (The) visibility_ceiling;
    }
];
```

§**9. Banner.** Note that NI always compiles `Story` and `Headline` texts, but does not always compile a `Story_Author`.

```
[ Banner;
BeginActivity(PRINTING_BANNER_TEXT_ACT);
if (ForActivity(PRINTING_BANNER_TEXT_ACT) == false) {
        VM_Style(HEADER_VMSTY);
        print (string) Story;
        VM_Style(NORMAL_VMSTY);
        new_line;
        print (string) Headline;
        #ifdef Story_Author;
        print " by ", (string) Story_Author;
        #endif; ! Story_Author
        new_line;
        VM_Describe_Release();
        print " / Inform 7 build ", (string) NI_BUILD_COUNT, " ";
        print "(I6/v"; inversion;
        print " lib ", (string) LibRelease, ") ";
        #Ifdef STRICT_MODE;
        print "S";
        #Endif; ! STRICT_MODE
        #Ifdef DEBUG;
        print "D";
        #Endif; ! DEBUG
        new_line;
    }
    EndActivity(PRINTING_BANNER_TEXT_ACT);
];
```

§10. Print Decimal Number. `DecimalNumber` is a trivial function which just prints a number, in decimal digits. It is left over from the I6 library's support routines for Glulx, where it was intended as a stub to pass to the Glulx `Glulx_PrintAnything` routine (which I7 does not use). In I7, however, it's also used as the default printing routine for new kinds of value.

```
[ DecimalNumber num; print num; ];
```

§11. Print English Number. Another traditional name, this: in fact it prints the number as text in whatever is the current language of play.

```
[ EnglishNumber n; LanguageNumber(n); ];
```

§12. Print Text. The routine for printing an I7 "text" value, which might text with or without substitutions.

```
[ PrintText x;
    if (x ofclass String) print (string) x;
    if (x ofclass Routine) (x)();
];
[ I7_String x; PrintText(x); ]; ! An alternative name now used only by extensions
```

§13. Print Or Run. This utility remains from the old I6 library: it essentially treats a property as textual and prints it where possible. Where the `no_break` flag is set, we expect the text to form only a small part of a paragraph, and it's inappropriate to break here: for instance, for printing the "printed name" of an object. Where the flag is clear, however, the text is expected to form its own paragraph.

Where `PrintOrRun` is used in breaking mode, which is only for a very few properties in I7 (indeed at present only `initial` and `description`), the routine called is given the chance to decide whether to print or not. It should return `true` or `false` according to whether it did so; this allows us to divide the paragraph or not accordingly.

```
[ PrintOrRun obj prop no_break  routine_return_value;
    !print "(", obj, ".", prop, ";", say__p, say__pc, ")";
    if (prop == 0) {
        print (name) prop; routine_return_value = true;
    } else {
        switch (metaclass(obj.prop)) {
            nothing:
                routine_return_value = false;
            String:
                print (string) obj.prop; !if (no_break == false) new_line;
                routine_return_value = true;
            Routine:
                routine_return_value = RunRoutines(obj, prop);
                !print "[", routine_return_value, "]";
        }
    }
    if (routine_return_value) {
        say__p = 1;
        if (no_break == false) {
            new_line;
            !print "(DP->", say__p, say__pc, ")";
```

```
            DivideParagraphPoint();
            !print "(to", say__p, say__pc, ")";
        }
    }
    !print "(-->", say__p, say__pc, ")";
    return routine_return_value;
];
```

§**14. Short Name Storage.** None of the following functions should be called for the Z-machine if the short name exceeds the size of the following buffer: whereas the Glulx implementation of `VM_PrintToBuffer` will safely truncate overlong text, that's impossible for the Z-machine, and horrible results will follow.

`CPrintOrRun` is a variation on `PrintOrRun`, simplified by not needing to handle entire paragraphs (so, no fuss about dividing) but complicated by having to capitalise the first letter. We do this by writing to the buffer and then altering the first character.

```
Array StorageForShortName buffer 250;
[ CPrintOrRun obj prop  v length i;
    if ((obj ofclass String or Routine) || (prop == 0))
        VM_PrintToBuffer (StorageForShortName, 160, obj);
    else {
        if (obj.prop == NULL) rfalse;
        if (metaclass(obj.prop) == Routine or String)
            VM_PrintToBuffer(StorageForShortName, 160, obj, prop);
        else return RunTimeError(2, obj, prop);
    }
    length = StorageForShortName-->0;
    StorageForShortName->WORDSIZE = VM_LowerToUpperCase(StorageForShortName->WORDSIZE);
    for (i=WORDSIZE: i<length+WORDSIZE: i++) print (char) StorageForShortName->i;
    if (i>WORDSIZE) say__p = 1;
    return;
];
[ Cap str nocaps;
    if (nocaps) print (string) str;
    else CPrintOrRun(str, 0);
];
```

§**15. Object Names I.** We now begin the work of printing object names. In the lowest level of this process we print just the name itself (without articles attached), and we do it by carrying out an activity.

```
[ PSN__ o;
    if (o == 0) { print (string) NOTHING__TX; rtrue; }
    switch (metaclass(o)) {
        Routine:  print "<routine ", o, ">"; rtrue;
        String:   print "<string ~", (string) o, "~>"; rtrue;
        nothing:  print "<illegal object number ", o, ">"; rtrue;
    }
    CarryOutActivity(PRINTING_THE_NAME_ACT, o);
];
```

§**16. Standard Name Printing Rule.** In its initial state, the "printing the name of" activity has just one rule: the following "for" rule.

```
Global caps_mode = false;
[ STANDARD_NAME_PRINTING_R obj;
    obj = parameter_object;
    if (obj == 0) {
        print (string) NOTHING__TX; return;
    }
    switch (metaclass(obj)) {
        Routine:  print "<routine ", obj, ">"; return;
        String:   print "<string ~", (string) obj, "~>"; return;
        nothing:  print "<illegal object number ", obj, ">"; return;
    }
    if (obj == player) {
        if (indef_mode == NULL && caps_mode) print (string) YOU__TX;
        else print (string) YOURSELF__TX;
        return;
    }
    #Ifdef LanguagePrintShortName;
    if (LanguagePrintShortName(obj)) return;
    #Endif; ! LanguagePrintShortName
    if (indef_mode && obj.&short_name_indef ~= 0 &&
        PrintOrRun(obj, short_name_indef, true) ~= 0) return;
    if (caps_mode &&
        obj.&cap_short_name ~= 0 && PrintOrRun(obj, cap_short_name, true) ~= 0) {
        caps_mode = false;
        return;
    }
    if (obj.&short_name ~= 0 && PrintOrRun(obj, short_name, true) ~= 0) return;
    print (object) obj;
];
```

§**17. Object Names II.** The second level of the system for printing object names handles the placing of articles in front of them: *the* red herring, *an* elephant, *Some* bread. The following routine allows us to choose:

(a) `obj`, the object whose name is to be printed;
(b) `acode`, the kind of article needed: capitalised definite (0), lower case uncapitalised definite (1), or uncapitalised indefinite (2);
(c) `pluralise`, a flag forcing to a plural form (e.g., "some" being the pluralised form of an indefinite article in English);
(d) `capitalise`, a flag forcing us to capitalise the article – it's by setting this that we can achieve the fourth option missing from (b), viz., capitalised indefinite. (All of this is a legacy design from a time when the I6 library did not support capitalised indefinite articles.)

The routine then looks after issues such as which contraction form to use: for instance, in English, whether to use "a" or "an" for the indefinite singular depends on the text of the object's name.

```
Global short_name_case;
[ PrefaceByArticle obj acode pluralise capitalise  i artform findout artval;
    if (obj provides articles) {
        artval=(obj.&articles)-->(acode+short_name_case*LanguageCases);
        if (capitalise)
```

```
            print (Cap) artval, " ";
        else
            print (string) artval, " ";
        if (pluralise) return;
        print (PSN__) obj; return;
    }
    i = GetGNAOfObject(obj);
    if (pluralise) {
        if (i < 3 || (i >= 6 && i < 9)) i = i + 3;
    }
    i = LanguageGNAsToArticles-->i;
    artform = LanguageArticles
        + 3*WORDSIZE*LanguageContractionForms*(short_name_case + i*LanguageCases);
    #Iftrue (LanguageContractionForms == 2);
    if (artform-->acode ~= artform-->(acode+3)) findout = true;
    #Endif; ! LanguageContractionForms
    #Iftrue (LanguageContractionForms == 3);
    if (artform-->acode ~= artform-->(acode+3)) findout = true;
    if (artform-->(acode+3) ~= artform-->(acode+6)) findout = true;
    #Endif; ! LanguageContractionForms
    #Iftrue (LanguageContractionForms == 4);
    if (artform-->acode ~= artform-->(acode+3)) findout = true;
    if (artform-->(acode+3) ~= artform-->(acode+6)) findout = true;
    if (artform-->(acode+6) ~= artform-->(acode+9)) findout = true;
    #Endif; ! LanguageContractionForms
    #Iftrue (LanguageContractionForms > 4);
    findout = true;
    #Endif; ! LanguageContractionForms
    #Ifdef TARGET_ZCODE;
    if (standard_interpreter ~= 0 && findout) {
        StorageForShortName-->0 = 160;
        @output_stream 3 StorageForShortName;
        if (pluralise) print (number) pluralise; else print (PSN__) obj;
        @output_stream -3;
        acode = acode + 3*LanguageContraction(StorageForShortName + 2);
    }
    #Ifnot; ! TARGET_GLULX
    if (findout) {
        if (pluralise)
            Glulx_PrintAnyToArray(StorageForShortName, 160, EnglishNumber, pluralise);
        else
            Glulx_PrintAnyToArray(StorageForShortName, 160, PSN__, obj);
        acode = acode + 3*LanguageContraction(StorageForShortName);
    }
    #Endif; ! TARGET_
    Cap (artform-->acode, ~~capitalise); ! print article
    if (pluralise) return;
    print (PSN__) obj;
];
```

§**18. Object Names III.** The routines accessible from outside this segment.

```
[ IndefArt obj i;
    if (obj == 0) { print (string) NOTHING__TX; rtrue; }
    i = indef_mode; indef_mode = true;
    if (obj has proper) { indef_mode = NULL; print (PSN__) obj; indef_mode = i; return; }
    if (obj provides article) {
        PrintOrRun(obj, article, true); print " ", (PSN__) obj; indef_mode = i;
        return;
    }
    PrefaceByArticle(obj, 2); indef_mode = i;
];
[ CIndefArt obj i;
    if (obj == 0) { CPrintOrRun(NOTHING__TX, 0); rtrue; }
    i = indef_mode; indef_mode = true;
    if (obj has proper) {
        indef_mode = NULL;
        caps_mode = true;
        print (PSN__) obj;
        indef_mode = i;
        caps_mode = false;
        return;
    }
    if (obj provides article) {
        CPrintOrRun(obj, article); print " ", (PSN__) obj; indef_mode = i;
        return;
    }
    PrefaceByArticle(obj, 2, 0, 1); indef_mode = i;
];
[ DefArt obj i;
    i = indef_mode; indef_mode = false;
    if ((~~obj ofclass Object) || obj has proper) {
        indef_mode = NULL; print (PSN__) obj; indef_mode = i;
        return;
    }
    PrefaceByArticle(obj, 1); indef_mode = i;
];
[ CDefArt obj i;
    i = indef_mode; indef_mode = false;
    if ((obj ofclass Object) && (obj has proper || obj == player)) {

        }
        !for (i=0:i<count:i++) print I7_SOO_SHUF->i, " "; print "^";
        v = (I7_SOO_SHUF->ct)+1;
        ct++; if (ct >= count) { ct = 0; ssd = 0; }
    }
    !print "Out v=", v, " ct=", ct, " ssd=", sd, "^";
    !print "Return ", v + ct*base + ssd*base*base, "^";
    return v + ct*base + ssd*base*base;
];
```

RTP Template B/rtpt

Purpose

To issue run-time problem messages, and to perform some run-time type checking which may issue such messages.

---

§**1. Reporting.** All RTPs are produced by calling the following routine, which takes one compulsory argument: `n`, the RTP number. When I7 is being used with the Inform user interface, it's important that these numbers correspond to the explanatory web pages stored within the interface application: those in turn are created by the `inrtps` utility. The interface knows to display these pages because it parses the printed output during play to look for the text layout produced by the following routine: so do not reformat RTPs without ensuring that corresponding changes have been made to the Inform user interface applications.

The arguments `par1`, `par2` and `par3` are optional parameters clarifying the message; `ln` is an optional parameter specifying a paragraph number in the original source text (though in fact I7 does not use this at present).

```
[ RunTimeProblem n par1 par2 par3 ln   i c;
    if (enable_rte == false) return;
    enable_rte = false;
    print "^*** Run-time problem P", n;
    if (ln) print " (at paragraph ", ln, " in the source text)";
    print ": ";
    switch(n) {
        RTP_BACKDROP:
            print "Tried to move ", (the) par1, " (a backdrop) to ", (the) par2,
                ", which is not a region.^";
        RTP_CANTCHANGE:
            print "Tried to change player to ", (the) par1,
                ", which is not a player-character.^";
        RTP_NOEXIT:
            print "Tried to change ", (the) par2, " exit of ", (the) par1,
                ", but it didn't seem to have such an exit to change.^";
        RTP_EXITDOOR:
            print "Tried to change ", (the) par2, " exit of ", (the) par1,
                ", but it led to a door, not a room.^";
        RTP_IMPREL:
            print "Tried to access an inappropriate relation for ", (the) par1,
                ", violating '";
            for (i=0: relation_metadata-->i ~= NULL: i=i+3) {
                c = relation_metadata-->(i+1);
                if (((c == Relation_VtoV) || (c == Relation_Sym_VtoV))
                    && (par2 == relation_metadata-->i))
                    print (string) relation_metadata-->(i+2), "'.^";

            print "You can't take the square root of a negative number.^";
        }
    print "^";
];
```

§**2. Low-Level Errors.** The following is a residue from the old I6 library, and most of its possible messages can't be seen in I7 use – for instance I7 has no timers or daemons, so error 4 is out of the question. But we retain the routine because the veneer code added by I6 requires it to be present.

```
Constant MAX_TIMERS = 0;
[ RunTimeError n p1 p2;
    #Ifdef DEBUG;
    print "** Library error ", n, " (", p1, ",", p2, ") **^** ";
    switch (n) {
    1:    print "preposition not found (this should not occur)";
    2:    print "Property value not routine or string: ~", (property) p2, "~ of ~", (name) p1,
                "~ (", p1, ")";
    3:    print "Entry in property list not routine or string: ~", (property) p2, "~ list of ~",
                (name) p1, "~ (", p1, ")";
    4:    print "Too many timers/daemons are active simultaneously.
                The limit is the library constant MAX_TIMERS (currently ",
                MAX_TIMERS, ") and should be increased";
    5:    print "Object ~", (name) p1, "~ has no ~time_left~ property";
    7:    print "The object ~", (name) p1, "~ can only be used as a player object if it has
                the ~number~ property";
    8:    print "Attempt to take random entry from an empty table array";
    9:    print p1, " is not a valid direction property number";
    10:   print "The player-object is outside the object tree";
    11:   print "The room ~", (name) p1, "~ has no ~description~ property";
    12:   print "Tried to set a non-existent pronoun using SetPronoun";
    13:   print "A 'topic' token can only be followed by a preposition";
    default: print "(unexplained)";
    }
    print " **^";
    #Ifnot;
```

```
    print "** Library error ", n, " (", p1, ",", p2, ") **^";
    #Endif; ! DEBUG
    RunTimeProblem(RTP_LOWLEVELERROR);
];
```

§**3. Argument Type Checking Failed.** This is called when run-time type checking for the argument of a phrase fails, so that no definition for the phrase can be applied.

```
[ ArgumentTypeFailed file line arg;
    RunTimeProblem(RTP_TYPECHECK, 0, 0, 0, line);
];
```

§**4. Return Type Checking Failed.** Similarly, though in a more restricted set of circumstances. NI can usually prove that the value returned by a phrase matches its supposed kind, but because of the deliberately weak type-checking within the kind of value "object" it will allow a broader kind of object to be returned when the requirement is for a narrower one. In such cases, it checks the result with the following routine. The value `V` is a valid "object", but that means it can be `nothing`, and we must check that it matches a given I7 kind `K` (where `nothing` is not valid).

```
[ CheckKindReturned V K;
    if (V ofclass K) return V;
    if (v == nothing) RunTimeProblem(RTP_DECIDEONNOTHING);
    else RunTimeProblem(RTP_DECIDEONWRONGKIND);
    return V;
];
```

§**5. Whether Provides.** This routine defines the phrase "if O provides P": there are three tests to pass, and if any of the three fail, we return `false`. (The `issue_rtp` flag, causing RTPs to be issued depending on which test fails, is never set when the routine is simply testing the condition.)

Firstly, P has to be a property known to I7. Secondly, there has to be permission either for this individual object to have it, or for its kind to have it, or its kind's kind, and so on. Thirdly, the object has to actually have the property in question at an I6 level – having permission to have it doesn't mean it actually does have.

```
[ WhetherProvides obj either_or p issue_rtp  off i textual a l;
    if (metaclass(obj) ~= Object) rfalse;
    if (p<0) p = ~p;
    if (either_or) {
        if (p < FBNA_PROP_NUMBER) off = attribute_offsets-->p;
        else off = attribute_offsets-->(50+p-FBNA_PROP_NUMBER);
    } else off = property_offsets-->p;
    if (off<0) {
        if (issue_rtp) RunTimeProblem(RTP_BADPROPERTY, obj);
        rfalse;
    }
    textual = property_metadata-->off; off++;
    if (ScanPropertyMetadata(obj, off)) jump PermissionFound;
    if (obj provides IK_0) {
        l = obj.IK_0;
        while (l > 0) {
            a = l*2;
```

```
            if (ScanPropertyMetadata(KindHierarchy-->a, off)) jump PermissionFound;
            l = KindHierarchy-->(a+1);
        }
    }
    if (issue_rtp) RunTimeProblem(RTP_UNPROVIDED, obj, textual);
    rfalse;
    .PermissionFound;
        if (either_or) rtrue;
        if (obj provides p) rtrue;
        if (issue_rtp) RunTimeProblem(RTP_UNSET, obj, textual);
        rfalse;
];
```

§**6. Scan Property Metadata.** The `property_metadata` table is a series of zero-terminated lists of objects (or class objects, representing I7 kinds). Each list corresponds to a single property; the position in the table is called the "offset" for the property. The following searches from a given offset.

```
[ ScanPropertyMetadata obj off i;
    for (i=off: property_metadata-->i >= 0: i++)
        if (obj == property_metadata-->i) rtrue;
    rfalse;
];
```

§**7. Get Either-Or Property.** If `p` represents a property, then `~p` (its bitwise negation) represents its logical negation. The bitwise negation will change the sign bit; since all properties are ordinarily positive, we can detect bitwise negation by looking for negative property numbers. (This could fail on Glulx story files above 1GB in size, but that's about 1000 times the size of the record-sized file created thus far.)

FBNA stands for First Boolean Not to be an Attribute, in the I6 sense. Some either/or (i.e., boolean) properties are stored as I6 attributes, others as I6 properties whose values are always `true` or `false`.

Note that we allow either/or properties to be *read* for any object, regardless of permissions, returning `false` if the object does not have the property. This is so that a description such as "open things" can be applied against any object without run-time errors, even though it is only normally valid for doors and containers.

```
[ GetEitherOrProperty o p;
    if (o == nothing) rfalse;
    if (p<0) p = ~p;
    if (WhetherProvides(o, true, p, false)) {
        if (p<FBNA_PROP_NUMBER) { if (o has p) rtrue; rfalse; }
        if ((o provides p) && (o.p)) rtrue;
    }
    rfalse;
];
```

§**8. Set Either-Or Property.** An attempt to *write* an either/or property which is not provided will, however, always produce a run-time problem.

```
[ SetEitherOrProperty o p negate adj;
    if (p<0) { p = ~p; negate = ~negate; }
    if (adj) {
        (adj)(o);
    } else if (WhetherProvides(o, true, p, true)) {
        if (negate) {
            if (p<FBNA_PROP_NUMBER) give o ~p; else o.p = false;
        } else {
            if (p<FBNA_PROP_NUMBER) give o p; else o.p = true;
        }
    }
];
```

§**9. Get Property For KOVs.** Similarly, but for properties belonging to values.

```
[ PropertyKOV kovp_array off inst per;
    per = kovp_array-->0;
    return kovp_array-->(1+(inst-1)*per+off);
];
```

§**10. Set Property For KOVs.** Similarly, but for properties belonging to values.

```
[ WritePropertyKOV kovp_array off inst state per;
    per = kovp_array-->0;
    kovp_array-->(1+(inst-1)*per+off) = state;
];
```

§**11. Value Property.** Some value properties belong to other values (those created in tables), and these are detected by being properties of the special `ValuePropertyHolder` pseudo-object – an I6 object which is not part of the world model, and not a valid I7 "object" value, but which is used in order that properties belonging to values are still I6 property numbers. `ValuePropertyHolder.P` is the table column address for this property; `obj` is then a value for the kind of value created by the table, so it is used as an index into the table column to get the address of the memory location storing the property value.

The `door_to` property, relevant only for doors, is called rather than read: this enables it to be an I6 routine returning the other side of the door from the one which the player is on.

```
[ ValueProperty obj pr;
    if (ValuePropertyHolder provides pr) {
        if ((obj<=0) || (obj > (ValuePropertyHolder.pr)-->0)) {
            RunTimeProblem(RTP_BADVALUEPROPERTY);
            rfalse;
        }
        return (ValuePropertyHolder.pr)-->(obj+COL_HSIZE);
    }
    if (obj == 0) { RunTimeProblem(RTP_PROPOFNOTHING, obj, pr); rfalse; }
    if ((pr == door_to) && (obj provides pr)) return obj.pr();
    if (WhetherProvides(obj, false, pr, true)) return obj.pr;
    rfalse;
];
```

§**12. Write Value Property.** This routine's name must consist of the read-value-property routine's name with the prefix `Write`, as that is how a reference to such a property is converted from an rvalue to an lvalue.

```
[ WriteValueProperty obj pr val;
    if (ValuePropertyHolder provides pr) {
        if ((obj<=0) || (obj > (ValuePropertyHolder.pr)-->0))
            return RunTimeProblem(RTP_BADVALUEPROPERTY);
        (ValuePropertyHolder.pr)-->(obj+COL_HSIZE) = val;
        return;
    }
    if (obj == 0) { RunTimeProblem(RTP_PROPOFNOTHING, obj, pr); rfalse; }
    if (WhetherProvides(obj, false, pr, true)) obj.pr = val;
];
```

Utilities Template B/utilt

Purpose

Miscellaneous utility routines for some fundamental I6 needs.

---

§**1. DigitToValue.** This takes a ZSCII or Unicode character code and returns its value as a digit, or returns -1 if it isn't a digit.

```
[ DigitToValue c n;
    n = c-'0';
    if ((n<0) || (n>9)) return -1;
    return n;
];
```

§**2. GenerateRandomNumber.** The following uses the virtual machine's RNG (via the I6 built-in function `random`) to produce a uniformly random integer in the range n to m inclusive, where n and m are allowed to be either way around; so that a random number between 17 and 4 is the same thing as a random number between 4 and 17, and there is therefore no pair of n and m corresponding to an empty range of values.

```
[ GenerateRandomNumber n m s;
    if (n==m) return n;
    if (n>m) { s = n; n = m; m = s; }
    n--;
    return random(m-n) + n;
];
```

§**3. GroupChildren.** The following runs through the child-objects of `par` in the I6 object tree, and moves those having a given property value together, to become the eldest children. It preserves the ordering in between those objects, and also in between those not having that property value. The property is required to be a common property.

We do this by temporarily moving objects into and out of `in_obj` and `out_obj`, objects which in all other circumstances never have children in the tree.

```
[ GroupChildren par prop value;
    while (child(par) ~= 0) {
        if (child(par).prop ~= value) move child(par) to out_obj;
        else move child(par) to in_obj;
    }
    while (child(in_obj) ~= 0)  move child(in_obj) to par;
    while (child(out_obj) ~= 0) move child(out_obj) to par;
    return child(par);
];
```

§**4. PrintSpaces.** Which prints a row of n spaces, for $n \geq 0$.

```
[ PrintSpaces n;
    while (n > 0) {
        print " ";
        n = n - 1;
    }
];
```

§**5. RunRoutines.** This function may not be very well-named, but the idea is to take a property of a given object and either to print it (and return `true`) if it's a string, and call it (and pass along its return value) if it's a routine. If the object does not provide the property, we act on the default value for the property if it has one, and otherwise do nothing (and return `false`).

The I6 pseudo-object `thedark` is used to give the impression that Darkness is a room in its own right, which is not really true. Note that it is not permitted to have properties other than the three named here: all other properties are redirected to the current location's object.

Properties with numbers under `INDIV_PROP_START` are "common properties". These come along with a table of default values, so that it is meaningful (in I6, anyway) to read them even when they are not provided (so that the address, returned by the `.&` operator, is zero).

```
[ RunRoutines obj prop;
    if (obj == thedark) obj = real_location;
    if ((obj.&prop == 0) && (prop >= INDIV_PROP_START)) rfalse;
    return obj.prop();
];
```

§**6. SwapWorkflags.** Recall that we have two general-purpose temporary attributes for each object: `workflag` and `workflag2`. The following swaps their values over for every object at once.

```
[ SwapWorkflags obj lst;
    objectloop (obj ofclass Object) {
        lst = false;
        if (obj has workflag2) lst = true;
        give obj ~workflag2;
        if (obj has workflag) give obj workflag2;
        give obj ~workflag;
        if (lst) give obj workflag;
    }
];
```

§**7. TestUseOption.** This routine, compiled by NI, returns `true` if the supplied argument is the number of a use option in force for the current run of NI, and `false` otherwise.

```
{-routine:TestUseOption}
```

§**8. IntegerDivide.** We can't simply use I6's `/` operator, as that translates directly into a virtual machine opcode which crashes on divide by zero.

```
[ IntegerDivide A B;
    if (B == 0) { RunTimeProblem(RTP_DIVZERO); rfalse; }
    return A/B;
];
```

§**9. IntegerRemainder.** Similarly.

```
[ IntegerRemainder A B;
    if (B == 0) { RunTimeProblem(RTP_DIVZERO); rfalse; }
    return A%B;
];
```

§**10. UnsignedCompare.** Comparison of I6 integers is normally signed, that is, treating the word as a twos-complement signed number, so that `$FFFF` is less than `0`, for instance. If we want to construe words as being unsigned integers, or as addresses, we need to compare them with the following routine, which returns 1 if $x > y$, 0 if $x = y$ and -1 if $x < y$.

```
[ UnsignedCompare x y u v;
    if (x == y) return 0;
    if (x < 0 && y >= 0) return 1;
    if (x >= 0 && y < 0) return -1;
    u = x&~WORD_HIGHBIT; v= y&~WORD_HIGHBIT;
    if (u > v) return 1;
    return -1;
];
```

§**11. ZRegion.** I7 contains many relics from I6, but here's a relic from I5: a routine which used to determine the metaclass of a value, before that concept was given a name. In I6 code, it can be implemented simply using `metaclass`, as the following shows. (The name is from "region of the Z-machine".)

```
[ ZRegion addr;
    switch (metaclass(addr)) {
        nothing: return 0;
        Object, Class: return 1;
        Routine: return 2;
        String: return 3;
    }
];
```

§**12. Library Messages.** This is another fossil, and probably soon to change.

```
[ GL__M a b c d;
    if ((actor ~= player) || (untouchable_silence)) rtrue;
    return L__M(a,b,c,d); ];
[ AGL__M a b c d;
    if (untouchable_silence) rtrue;
    return L__M(a,b,c,d); ];
```

Number Template B/numt

Purpose
Support for parsing integers.

§**1. Understanding.** In our target virtual machines, numbers are stored in twos-complement form, so that a 16-bit VM can hold the range of integers $-2^{15} = -32768$ to $2^{15} - 1 = +32767$, while a 32-bit VM can hold $-2^{31} = -2147483648$ to $2^{31} - 1 = +2147483647$: the token below accepts exactly those ranges.

```
[ DECIMAL_TOKEN wnc wna r n wa wl sign base digit digit_count original_wn group_wn;
    wnc = wn; original_wn = wn; group_wn = wn;
{-call:compile_number_grammar}
    wn = wnc;
    r = ParseTokenStopped(ELEMENTARY_TT, NUMBER_TOKEN);
    if ((r == GPR_NUMBER) && (parsed_number ~= 10000)) return r;
    wn = wnc;
    wa = WordAddress(wn);
    wl = WordLength(wn);
    sign = 1; base = 10; digit_count = 0;
    if (wa->0 ~= '-' or '$' or '0' or '1' or '2' or '3' or '4'
        or '5' or '6' or '7' or '8' or '9')
        return GPR_FAIL;
    if (wa->0 == '-') { sign = -1; wl--; wa++; }
    if (wl == 0) return GPR_FAIL;
    n = 0;
    while (wl > 0) {
        if (wa->0 >= 'a') digit = wa->0 - 'a' + 10;
        else digit = wa->0 - '0';
        digit_count++;
        switch (base) {
            2:  if (digit_count == 17) return GPR_FAIL;
            10:
                #Iftrue (WORDSIZE == 2);
                if (digit_count == 6) return GPR_FAIL;
                if (digit_count == 5) {
                    if (n > 3276) return GPR_FAIL;
                    if (n == 3276) {
                        if (sign == 1 && digit > 7) return GPR_FAIL;
                        if (sign == -1 && digit > 8) return GPR_FAIL;
                    }
                }
                #Ifnot; ! i.e., if (WORDSIZE == 4)
                if (digit_count == 11) return GPR_FAIL;
                if (digit_count == 10) {
                    if (n > 214748364) return GPR_FAIL;
                    if (n == 214748364) {
                        if (sign == 1 && digit > 7) return GPR_FAIL;
                        if (sign == -1 && digit > 8) return GPR_FAIL;
                    }
```

```
                }
                #Endif;
            16: if (digit_count == 5) return GPR_FAIL;
        }
        if (digit >= 0 && digit < base) n = base*n + digit;
        else return GPR_FAIL;
        wl--; wa++;
    }
    parsed_number = n*sign; wn++;
    return GPR_NUMBER;
];
```

§**2. Truth states.** And although truth states are not strictly speaking numbers, this seems as good a point as any to parse them:

```
[ TRUTH_STATE_TOKEN original_wn wd;
    original_wn = wn;
{-call:compile_truth_state_grammar}
    wn = original_wn;
    wd = NextWordStopped();
    if (wd == 'true') { parsed_number = 1; return GPR_NUMBER; }
    if (wd == 'false') { parsed_number = 0; return GPR_NUMBER; }
    wn = original_wn;
    return GPR_FAIL;
];
```

Time Template B/timet

Purpose
Support for parsing and printing times of day.

§**1. Rounding.** The following rounds a numerical value `t1` to the nearest unit of `t2`; for instance, if `t2` is 5 then it rounds to the nearest 5.

```
[ RoundOffTime t1 t2; return ((t1+t2/2)/t2)*t2; ];
```

§**2. Square Root.** This is an old algorithm for extracting binary square roots, taking 2 bits at a time. We start out with `one` at the highest bit which isn't the sign bit; that used to be worked out as `WORD_HIGHBIT/2`, but this caused unexpected portability problems (exposing a minor bug in Inform and also glulxe) because of differences in how C compilers handle signed division of constants in the case where the dividend is -2^{31}, the unique number which cannot be negated in 32-bit twos complement arithmetic.

```
[ SquareRoot num
    op res one;
    op = num;
    if (num < 0) { RunTimeProblem(RTP_NEGATIVEROOT); return 1; }
    ! "one" starts at the highest power of four <= the argument.
    for (one = WORD_NEXTTOHIGHBIT: one > op: one = one/4) ;
    while (one ~= 0) {
        !print "Round: op = ", op, " res = ", res, ", res**2 = ", res*res, " one = ", one, "^";
        if (op >= res + one) {
            op = op - res - one;
            res = res + one*2;
        }
        res = res/2;
        one = one/4;
    }
    !print "Res is ", res, "^";
    return res;
];
```

§**3. Cube Root.** The following is an iterative scheme for finding cube roots by Newton-Raphson approximation, not a great method but which, on the narrow ranges of integers we deal with, is good enough. The square root is used only as a sighting shot.

```
[ CubeRoot num x y n;
    if (num < 0) x = -SquareRoot(-num); else x = SquareRoot(num);
    for (n=0: (y ~= x) && (n++ < 100): y = x, x = (2*x + num/x/x)/3) ;
    return x;
];
```

§**4. Digital Printing.** For instance, “2:06 am”.

```
[ PrintTimeOfDay t h aop;
    if (t<0) { print "<no time>"; return; }
    if (t >= TWELVE_HOURS) { aop = "pm"; t = t - TWELVE_HOURS; } else aop = "am";
    h = t/ONE_HOUR; if (h==0) h=12;
    print h, ":";
    if (t%ONE_HOUR < 10) print "0"; print t%ONE_HOUR, " ", (string) aop;
];
```

§**5. Analogue Printing.** For instance, “six minutes past two”.

```
[ PrintTimeOfDayEnglish t h m dir aop;
    h = (t/ONE_HOUR) % 12; m = t%ONE_HOUR; if (h==0) h=12;
    if (m==0) { print (number) h, " o'clock"; return; }
    dir = "past";
    if (m > HALF_HOUR) { m = ONE_HOUR-m; h = (h+1)%12; if (h==0) h=12; dir = "to"; }
    switch(m) {
        QUARTER_HOUR: print "quarter"; HALF_HOUR: print "half";
        default: print (number) m;
            if (m%5 ~= 0) {
                if (m == 1) print " minute"; else print " minutes";
            }
    }
    print " ", (string) dir, " ", (number) h;
];
```

§**6. Understanding.** This I6 grammar token converts words in the player's command to a valid I7 time, and is heavily based on the one presented as a solution to an exercise in the DM4.

```
[ TIME_TOKEN first_word second_word at length flag
    illegal_char offhour hr mn i original_wn;
    original_wn = wn;
{-call:compile_time_grammar}
    wn = original_wn;
    first_word = NextWordStopped();
    switch (first_word) {
        'midnight': parsed_number = 0; return GPR_NUMBER;
        'midday', 'noon': parsed_number = TWELVE_HOURS;
        return GPR_NUMBER;
    }
    ! Next try the format 12:02
    at = WordAddress(wn-1); length = WordLength(wn-1);
    for (i=0: i<length: i++) {
        switch (at->i) {
            ':': if (flag == false && i>0 && i<length-1) flag = true;
            else illegal_char = true;
            '0', '1', '2', '3', '4', '5', '6', '7', '8', '9': ;
            default: illegal_char = true;
        }
    }
    if (length < 3 || length > 5 || illegal_char) flag = false;
```

```
    if (flag) {
        for (i=0: at->i~=':': i++, hr=hr*10) hr = hr + at->i - '0';
        hr = hr/10;
        for (i++: i<length: i++, mn=mn*10) mn = mn + at->i - '0';
        mn = mn/10;
        second_word = NextWordStopped();
        parsed_number = HoursMinsWordToTime(hr, mn, second_word);
        if (parsed_number == -1) return GPR_FAIL;
        if (second_word ~= 'pm' or 'am') wn--;
        return GPR_NUMBER;
    }
    ! Lastly the wordy format
    offhour = -1;
    if (first_word == 'half') offhour = HALF_HOUR;
    if (first_word == 'quarter') offhour = QUARTER_HOUR;
    if (offhour < 0) offhour = TryNumber(wn-1);
    if (offhour < 0 || offhour >= ONE_HOUR) return GPR_FAIL;
    second_word = NextWordStopped();
    switch (second_word) {
        ! "six o'clock", "six"
        'o^clock', 'am', 'pm', -1:
            hr = offhour; if (hr > 12) return GPR_FAIL;
        ! "quarter to six", "twenty past midnight"
        'to', 'past':
            mn = offhour; hr = TryNumber(wn);
            if (hr <= 0) {
                switch (NextWordStopped()) {
                    'noon', 'midday': hr = 12;
                    'midnight': hr = 0;
                    default: return GPR_FAIL;
                }
            }
            if (hr >= 13) return GPR_FAIL;
            if (second_word == 'to') {
                mn = ONE_HOUR-mn; hr--; if (hr<0) hr=23;
            }
            wn++; second_word = NextWordStopped();
        ! "six thirty"
        default:
            hr = offhour; mn = TryNumber(--wn);
            if (mn < 0 || mn >= ONE_HOUR) return GPR_FAIL;
            wn++; second_word = NextWordStopped();
    }
    parsed_number = HoursMinsWordToTime(hr, mn, second_word);
    if (parsed_number < 0) return GPR_FAIL;
    if (second_word ~= 'pm' or 'am' or 'o^clock') wn--;
    return GPR_NUMBER;
];

[ HoursMinsWordToTime hour minute word x;
    if (hour >= 24) return -1;
    if (minute >= ONE_HOUR) return -1;
    x = hour*ONE_HOUR + minute; if (hour >= 13) return x;
    x = x % TWELVE_HOURS; if (word == 'pm') x = x + TWELVE_HOURS;
```

```
    if (word ~= 'am' or 'pm' && hour == 12) x = x + TWELVE_HOURS;
    return x;
];
```

§**7. Relative Time Token.** "Time" is an interesting kind of value since it can hold two conceptually different ways of thinking about time: absolute times, such as "12:03 PM", and also relative times, like "ten minutes". For parsing purposes, these are completely different from each other, and the time token above handles only absolute times; we need the following for relative ones.

```
[ RELATIVE_TIME_TOKEN first_word second_word offhour mult mn original_wn;
    original_wn = wn;
    wn = original_wn;
    first_word = NextWordStopped(); wn--;
    if (first_word == 'an' or 'a//') mn=1; else mn=TryNumber(wn);
    if (mn == -1000) {
        first_word = NextWordStopped();
        if (first_word == 'half') offhour = HALF_HOUR;
        if (first_word == 'quarter') offhour = QUARTER_HOUR;
        if (offhour > 0) {
            second_word = NextWordStopped();
            if (second_word == 'of') second_word = NextWordStopped();
            if (second_word == 'an') second_word = NextWordStopped();
            if (second_word == 'hour') {
                parsed_number = offhour;
                return GPR_NUMBER;
            }
        }
        return GPR_FAIL;
    }
    wn++;
    first_word = NextWordStopped();
    switch (first_word) {
        'minutes', 'minute': mult = 1;
        'hours', 'hour': mult = 60;
        default: return GPR_FAIL;
    }
    parsed_number = mn*mult;
    if (mult == 60) {
        mn=TryNumber(wn);
        if (mn ~= -1000) {
            wn++;
            first_word = NextWordStopped();
            if (first_word == 'minutes' or 'minute')
                parsed_number = parsed_number + mn;
            else wn = wn - 2;
        }
    }
    return GPR_NUMBER;
];
```

§8. During Scene Matching.

```
[ DuringSceneMatching prop sc;
    for (sc=0: sc<NUMBER_SCENES_CREATED: sc++)
        if ((scene_status-->sc == 1) && (prop(sc+1))) rtrue;
    rfalse;
];
```

§9. Scene Questions.

```
[ SceneUtility sc task;
    if (sc <= 0) return 0;
    if (task == 1 or 2) {
        if (scene_endings-->(sc-1) == 0) return RunTimeProblem(RTP_SCENEHASNTSTARTED, sc);
    } else {
        if (scene_endings-->(sc-1) <= 1) return RunTimeProblem(RTP_SCENEHASNTENDED, sc);
    }
    switch (task) {
        1: return (the_time - scene_started-->(sc-1))%(TWENTY_FOUR_HOURS);
        2: return scene_started-->(sc-1);
        3: return (the_time - scene_ended-->(sc-1))%(TWENTY_FOUR_HOURS);
        4: return scene_ended-->(sc-1);
    }
];
```

Tables Template B/tabt

Purpose

To read, write, search and allocate rows in the Table data structure.

§**1. Format.** The I7 Table structure is not to be confused with the I6 `table` form of array: it is essentially a two-dimensional array which has some metadata at the top of each column.

The run-time representation for a Table is the address `T` of an I6 `table` array: that is, `T-->0` holds the number of columns (which is at most 99) and `T-->i` is the address of column number `i`. Columns are therefore numbered from 1 to `T-->0`, but they are also identified by an ID number of 100 or more, with each different column name having its own ID number. (This is so that multiple tables can share columns with the same name, and correlate them: it also means that NI's type-checking machinery can know the kind of value of a table entry from the name of the column alone.)

Each column `C` is also a `table` array, with `C-->1` holding the unique ID number for the column's name, `C-->2` holding the blank entry flags offset and `C-->3` up to `C-->(C-->0)` holding the entries.

`C-->1` also contains four upper bit flags. These are also defined in "Tables.w" in the NI source, and the values must agree.

```
Constant TB_COLUMN_SIGNED      $4000;
Constant TB_COLUMN_TOPIC       $2000;
Constant TB_COLUMN_DONTSORTME  $1000;
Constant TB_COLUMN_NOBLANKBITS $0800;
Constant TB_COLUMN_CANEXCHANGE $0400;
Constant TB_COLUMN_ALLOCATED   $0200;
Constant TB_COLUMN_NUMBER      $01ff; ! Mask to remove upper bit flags
Constant COL_HSIZE 2; ! Column header size: two words (ID/flags, blank bits)
```

§**2. Find Column.** Columns can be referenced either by their physical column numbers – from 1 to, potentially, 99 – or else by unique ID numbers associated with column names. For instance, if a table has a column called "liquid capacity", then all references to its "liquid capacity entry" are via the ID number associated with this column name, which will be $\geq$ 100 and on the other hand $\leq$ `TB_COLUMN_NUMBER`. At present, this is only 511, so there can be at most 411 different column names across all the tables present in the source text. (It is just about possible to imagine this being a problem on a very large work, so we will probably one day revise the above to make use of the larger word-size in Glulx and so raise this limit. But so far nobody has got even close to it.)

```
[ TableFindCol tab col f i no_cols n;
    no_cols = tab-->0;
    for (i=1: i<=no_cols: i++)
        if (col == ((tab-->i)-->1) & TB_COLUMN_NUMBER) return i;
    if (f) { RunTimeProblem(RTP_TABLE_NOCOL, tab); return 0; }
    return 0;
];
```

§**3. Number of Rows.** The columns in a table can be assumed all to have the same height (i.e., number of rows): thus the number of rows in `T` can be calculated by looking at column 1, thus...

```
[ TableRows tab; return ((tab-->1)-->0) - COL_HSIZE; ];
```

§**4. Blanks.** Each table entry is stored in a single word in memory: indeed, column `C` row `R` is at address `(T-->C)-->(R+COL_HSIZE)`.

But this is not sufficient storage in all cases, because each entry can be either a value or can be designated "blank". Since, for some columns at least, the possible values include every number, we find that we have to store $2^{16}+1$ possibilities given only a 16-bit memory word. (Well, or $2^{32}+1$ with a 32-bit word, depending on the virtual machine.) This cannot be done.

We therefore need, at least in some cases, an additional bit of storage for each table entry which indicates whether or not it is blank. If we provided such a bit for every table entry, that would be a fairly simple system to implement, but it would also be wasteful of memory, with an overhead of about 5% in practice: and memory in the virtual machine is in very short supply. The reason such a system would be wasteful is that many columns are known to hold values which are in a narrow range; for instance, a time of day cannot exceed 1440, and there will never be more than 10,000 rulebooks or scenes, and so on. For such columns it would be more efficient and indeed faster to indicate blankness by using an exceptional value in the memory cell which is such that it cannot be valid for the kind of value stored in the column. We therefore provide a "blanks bitmap" for only some columns.

This leads us to define the following dummy value, chosen so that it is both impossible for most kinds of value – which is easy to arrange – and also unlikely for even those kinds of value where it is legal. For instance, -1 would be impossible for enumerative kinds of value such as rulebooks and scenes, but it would be a poor choice for the dummy value because it occurs pretty often as an integer. Instead we use the constant `IMPROBABLE_VALUE`, whose value depends on the word size of the virtual machine, and which is declared in "Definitions.i6t".

An entry is therefore blank if and only if either

(a) its column has no blanks bitmap and the stored entry is `TABLE_NOVALUE`, or
(b) its column does have a blanks bitmap, the blanks bit for this entry is set, and the stored entry is also `TABLE_NOVALUE`.

To look up the blanks bitmap is a little slower than to access the stored entry directly. Most of the time, entries accessed will be non-blank: so it is efficient to have a system where we can quickly determine this. If we look at the entry and find that it is not `TABLE_NOVALUE`, then we know it is not a blank. If we find that it is `TABLE_NOVALUE`, on the other hand, then quite often the column has no blanks bitmap and again we have a quick answer: it's blank. Only if the column also has a blanks bitmap do we need to check that we haven't got a false negative. (The more improbable `TABLE_NOVALUE` is as a stored value, the rarer it is that we have to check the blanks bitmap for a non-blank entry.)

```
Constant TABLE_NOVALUE = IMPROBABLE_VALUE;
```

§**5. Masks.** The blanks bitmaps are stored as bytes; we therefore need a quick way to test or set whether bit number i of a byte is zero, where $0 \leq i \leq 7$. I6 provides no very useful operators here, whereas memory lookup is cheap, so we use two arrays of bitmaps:

```
Array CheckTableEntryIsBlank_LU
    -> $$00000001
        $$00000010
        $$00000100
        $$00001000
        $$00010000
        $$00100000
        $$01000000
        $$10000000;
Array CheckTableEntryIsNonBlank_LU
    -> $$11111110
        $$11111101
        $$11111011
        $$11110111
        $$11101111
        $$11011111
        $$10111111
        $$01111111;
```

§**6. Testing Blankness.** The following routine is the one which checks that there is no false negative: it should be used when we know that the table entry is `TABLE_NOVALUE` and we need to check the blank bit, if there is one, to make sure the entry is indeed blank.

The second word in the column table header, `C-->2`, holds the address of the blanks bitmap: this in turn contains one bit for each row, starting with the least significant bit of the first byte. If the table contains a number of rows which isn't a multiple of 8, the spare bits at the end of the last byte in the blanks bitmap are wasted, but this is an acceptable overhead in practice.

```
[ CheckTableEntryIsBlank tab col row i at;
    if (col >= 100) col = TableFindCol(tab, col);
    if (col == 0) rtrue;
    if ((tab-->col)-->(row+COL_HSIZE) ~= TABLE_NOVALUE) {
        print "*** CTEIB on nonblank value ", tab, " ", col, " ", row, " ***^";
    }
    if (((tab-->col)-->1) & TB_COLUMN_NOBLANKBITS) rtrue;
    row--;
    at = ((tab-->col)-->2) + (row/8);
    if ((TB_Blanks->at) & (CheckTableEntryIsBlank_LU->(row%8))) rtrue;
    rfalse;
];
```

§**7. Force Entry Blank.** We blank a table cell by storing `TABLE_NOVALUE` in its entry word and also setting the relevant bit in the blanks bitmap, if there is one.

We need to be careful if the column holds a kind of value where values are pointers to blocks of allocated memory, because if so then overwriting such a value might lead to a memory leak. So in such cases we call `BlkFree` to free the memory block. (Note that each memory block is pointed to by one and only one I7 value at any given time: we are using them as values, not pointers to values. So if this reference is deleted, it's by definition the only one.) `TABLE_NOVALUE` is chosen such that it cannot be an address of a memory block, which is convenient here. (The value 0 means "no memory block allocated yet".)

```
[ ForceTableEntryBlank tab col row i at oldv flags;
    if (col >= 100) col = TableFindCol(tab, col);
    if (col == 0) rtrue;
    flags = (tab-->col)-->1;
    oldv = (tab-->col)-->(row+COL_HSIZE);
    if ((flags & TB_COLUMN_ALLOCATED) && (oldv ~= 0 or TABLE_NOVALUE))
        BlkFree(oldv);
    (tab-->col)-->(row+COL_HSIZE) = TABLE_NOVALUE;
    if (flags & TB_COLUMN_NOBLANKBITS) return;
    row--;
    at = ((tab-->col)-->2) + (row/8);
    (TB_Blanks->at) = (TB_Blanks->at) | (CheckTableEntryIsBlank_LU->(row%8));
];
```

§**8. Force Entry Non-Blank.** To unblank a cell, we need to clear the relevant bit in the bitmap. We then go on to write a new value in to the entry – thus overwriting the `TABLE_NOVALUE` value – but that isn't done here; the expectation is that whoever calls this routine is just about to write a new entry anyway.

The exception is again for columns holding a kind of value pointing to a memory block, where we create a suitable initialised but uninteresting memory block for the KOV in question, and set the entry to that.

```
[ ForceTableEntryNonBlank tab col row i at oldv flags tc kov j;
    if (col >= 100) col=TableFindCol(tab, col);
    if (col == 0) rtrue;
    if (((tab-->col)-->1) & TB_COLUMN_NOBLANKBITS) return;
    flags = (tab-->col)-->1;
    oldv = (tab-->col)-->(row+COL_HSIZE);
    if ((flags & TB_COLUMN_ALLOCATED) &&
        (oldv == 0 or TABLE_NOVALUE)) {
        kov = UNKNOWN_TY;
        tc = ((tab-->col)-->1) & TB_COLUMN_NUMBER;
        for (j=0: TC_KOVs-->j: j=j+3)
            if (TC_KOVs-->j == tc) {
                kov = TC_KOVs-->(j+1); break;
            }
        if (kov ~= UNKNOWN_TY)
            (tab-->col)-->(row+COL_HSIZE) = BlkValueCreate(kov, 0, TC_KOVs-->(j+2));
    }
    row--;
    at = ((tab-->col)-->2) + (row/8);
    (TB_Blanks->at) = (TB_Blanks->at) & (CheckTableEntryIsNonBlank_LU->(row%8));
];
```

§**9. Swapping Blank Bits.** When sorting a table, we obviously need to swap rows from time to time; if any of its columns have blanks bitmaps, then the relevant bits in them need to be swapped to match, and the following routine performs this operation for two rows in a given column.

```
[ TableSwapBlankBits tab row1 row2 col at1 at2 bit1 bit2;
    if (col >= 100) col=TableFindCol(tab, col);
    if (col == 0) rtrue;
    if (((tab-->col)-->1) & TB_COLUMN_NOBLANKBITS) return;
    row1--;
    at1 = ((tab-->col)-->2) + (row1/8);
    row2--;
    at2 = ((tab-->col)-->2) + (row2/8);
    bit1 = ((TB_Blanks->at1) & (CheckTableEntryIsBlank_LU->(row1%8)));
    bit2 = ((TB_Blanks->at2) & (CheckTableEntryIsBlank_LU->(row2%8)));
    if (bit1) bit1 = true;
    if (bit2) bit2 = true;
    if (bit1 == bit2) return;
    if (bit1) {
        (TB_Blanks->at1)
            = (TB_Blanks->at1) & (CheckTableEntryIsNonBlank_LU->(row1%8));
        (TB_Blanks->at2)
            = (TB_Blanks->at2) | (CheckTableEntryIsBlank_LU->(row2%8));
    } else {
        (TB_Blanks->at1)
            = (TB_Blanks->at1) | (CheckTableEntryIsBlank_LU->(row1%8));
        (TB_Blanks->at2)
            = (TB_Blanks->at2) & (CheckTableEntryIsNonBlank_LU->(row2%8));
    }
];
```

§**10. Moving Blank Bits Down.** Another common table operation is to compress it by moving all the blank rows down to the bottom, so that non-blank rows occur in a contiguous block at the top: this means table sorting can be done without having to refer continually to the blanks bitmaps. The following operation is useful for keeping the blanks bitmaps up to date when blank rows are moved down.

```
[ TableMoveBlankBitsDown tab row1 row2 col at atp1 bit rx;
    if (col >= 100) col=TableFindCol(tab, col);
    if (col == 0) rtrue;
    if (((tab-->col)-->1) & TB_COLUMN_NOBLANKBITS) return;
    row1--; row2--;
    ! Read blank bit for row1:
    at = ((tab-->col)-->2) + (row1/8);
    bit = ((TB_Blanks->at) & (CheckTableEntryIsBlank_LU->(row1%8)));
    if (bit) bit = true;
    ! Loop through, setting each blank bit to the next:
    for (rx=row1:rx<row2:rx++) {
        atp1 = ((tab-->col)-->2) + ((rx+1)/8);
        at = ((tab-->col)-->2) + (rx/8);
        if ((TB_Blanks->atp1) & (CheckTableEntryIsBlank_LU->((rx+1)%8))) {
            (TB_Blanks->at)
                = (TB_Blanks->at) | (CheckTableEntryIsBlank_LU->(rx%8));
        } else {
            (TB_Blanks->at)
```

```
                = (TB_Blanks->at) & (CheckTableEntryIsNonBlank_LU->(rx%8));
        }
    }
    ! Write bit to blank bit for row2:
    at = ((tab-->col)-->2) + (row2/8);
    if (bit) {
        (TB_Blanks->at)
            = (TB_Blanks->at) | (CheckTableEntryIsBlank_LU->(row2%8));
    } else {
        (TB_Blanks->at)
            = (TB_Blanks->at) & (CheckTableEntryIsNonBlank_LU->(row2%8));
    }
];
```

§**11. Table Row Corresponding.** `TableRowCorr(T, C, V)` returns the first row on which value `V` appears in column `C` of table `T`, or prints an error if it doesn't.

`ExistsTableRowCorr(T, C, V)` returns the first row on which `V` appears in column `C` of table `T`, or 0 if `V` does not occur at all. If the column is a topic, then we match the entry as a snippet against the value as a general parsing routine.

```
[ TableRowCorr tab col lookup_value lookup_col i j f;
    if (col >= 100) col=TableFindCol(tab, col, true);
    lookup_col = tab-->col;
    j = lookup_col-->0 - COL_HSIZE;
    f=0;
    if (((tab-->col)-->1) & TB_COLUMN_ALLOCATED) f=1;
    for (i=1:i<=j:i++) {
        if ((lookup_value == TABLE_NOVALUE) &&
            (CheckTableEntryIsBlank(tab,col,i))) continue;
        if (f) {
            if (BlkValueCompare(lookup_col-->(i+COL_HSIZE), lookup_value) == 0)
                return i;
        } else {
            if (lookup_col-->(i+COL_HSIZE) == lookup_value) return i;
        }
    }
    return RunTimeProblem(RTP_TABLE_NOCORR, tab);
];
[ ExistsTableRowCorr tab col entry i k v f kov;
    if (col >= 100) col=TableFindCol(tab, col);
    if (col == 0) rfalse;
    f=0;
    if (((tab-->col)-->1) & TB_COLUMN_TOPIC) f=1;
    else if (((tab-->col)-->1) & TB_COLUMN_ALLOCATED) f=2;
    k = TableRows(tab);
    for (i=1:i<=k:i++) {
        ! print "Checking row ", i, "^";
        v = (tab-->col)-->(i+COL_HSIZE);
        if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,i))) continue;
        switch (f) {
            1: if ((v)(entry/100, entry%100) ~= GPR_FAIL) return i;
            2: if (BlkValueCompare(v, entry) == 0) return i;
```

```
            default: if (v == entry) return i;
        }
    }
    ! print "Giving up^";
    return 0;
];
```

§**12. Table Look Up Corresponding Row.** `TableLookUpCorr(T, C1, C2, V)` finds the first row on which value `V` appears in column `C2`, and returns the corresponding value in `C1`, or prints an error if the value `V` cannot be found or has no corresponding value in `C1`.

`ExistsTableLookUpCorr(T, C1, C2, V)` returns `true` if the operation `TableLookUpCorr(T, C1, C2, V)` can be done, `false` otherwise.

```
[ TableLookUpCorr tab col1 col2 lookup_value write_flag write_value cola1 cola2 i j v f;
    if (col1 >= 100) col1=TableFindCol(tab, col1, true);
    if (col2 >= 100) col2=TableFindCol(tab, col2, true);
    cola1 = tab-->col1;
    cola2 = tab-->col2;
    j = cola2-->0;
    f=0;
    if (((tab-->col2)-->1) & TB_COLUMN_ALLOCATED) f=1;
    for (i=1+COL_HSIZE:i<=j:i++) {
        if (f) {
            if (BlkValueCompare(cola2-->i, lookup_value) ~= 0) continue;
        } else {
            if (cola2-->i ~= lookup_value) continue;
        }
        if (write_flag) {
            ForceTableEntryNonBlank(tab,col1,i-COL_HSIZE);
            cola1-->i = write_value;
            rfalse;
        }
        v = cola1-->i;
        if ((v == TABLE_NOVALUE) &&
            (CheckTableEntryIsBlank(tab,col1,i-COL_HSIZE))) continue;
        return v;
    }
    return RunTimeProblem(RTP_TABLE_NOCORR, tab);
];
[ ExistsTableLookUpCorr tab col1 col2 lookup_value cola1 cola2 i j f;
    if (col1 >= 100) col1=TableFindCol(tab, col1, false);
    if (col2 >= 100) col2=TableFindCol(tab, col2, false);
    if (col1*col2 == 0) rfalse;
    cola1 = tab-->col1; cola2 = tab-->col2;
    j = cola2-->0;
    f=0;
    if (((tab-->col2)-->1) & TB_COLUMN_ALLOCATED) f=1;
    for (i=1+COL_HSIZE:i<=j:i++) {
        if (f) {
            if (BlkValueCompare(cola2-->i, lookup_value) ~= 0) continue;
        } else {
            if (cola2-->i ~= lookup_value) continue;
```

```
        }
        if ((cola1-->i == TABLE_NOVALUE) &&
            (CheckTableEntryIsBlank(tab,col1,i-COL_HSIZE))) continue;
        rtrue;
    }
    rfalse;
];
```

§13. Table Look Up Entry. `TableLookUpEntry(T, C, R)` returns the value at column `C`, row `R`, printing an error if that doesn't exist.

`ExistsTableLookUpEntry(T, C, R)` returns true if a value exists at column `C`, row `R`, false otherwise.

```
[ TableLookUpEntry tab col index write_flag write_value v;
    if (col >= 100) col=TableFindCol(tab, col, true);
    if ((index < 1) || (index > TableRows(tab)))
        return RunTimeProblem(RTP_TABLE_NOROW, tab, index);
    if (write_flag) {
        switch(write_flag) {
            1: ForceTableEntryNonBlank(tab,col,index);
                (tab-->col)-->(index+COL_HSIZE) = write_value;
            2: ForceTableEntryNonBlank(tab,col,index);
                (tab-->col)-->(index+COL_HSIZE) =
                    ((tab-->col)-->(index+COL_HSIZE)) + write_value;
            3: ForceTableEntryNonBlank(tab,col,index);
                (tab-->col)-->(index+COL_HSIZE) =
                    ((tab-->col)-->(index+COL_HSIZE)) - write_value;
            4: ForceTableEntryBlank(tab,col,index);
            5: ForceTableEntryNonBlank(tab,col,index);
                return ((tab-->col)-->(index+COL_HSIZE));
        }
        rfalse;
    }
    v = ((tab-->col)-->(index+COL_HSIZE));
    if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,index)))
        return RunTimeProblem(RTP_TABLE_NOENTRY, tab, col, index);
    return v;
];
[ ExistsTableLookUpEntry tab col index v;
    if (col >= 100) col=TableFindCol(tab, col);
    if (col == 0) rfalse;
    if ((index<1) || (index > TableRows(tab))) rfalse;
    v = ((tab-->col)-->(index+COL_HSIZE));
    if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,index)))
        rfalse;
    rtrue;
];
```

§14. Blank Rows. `TableRowIsBlank(T, R)` returns true if row `R` of table `T` is blank. (`R` must be a legal row number.)

`TableBlankOutRow(T, R)` fills row `R` of table `T` with blanks. (`R` must be a legal row number.)

`TableBlankRows(T)` returns the number of blank rows in `T`.

`TableFilledRows(T)` returns the number of non-blank rows in `T`.

`TableBlankRow(T)` finds the first blank row in `T`.

```
[ TableRowIsBlank tab j k;
    for (k=1:k<=tab-->0:k++) {
        if (((tab-->k)-->(j+COL_HSIZE)) ~= TABLE_NOVALUE) rfalse;
        if (CheckTableEntryIsBlank(tab, k, j) == false) rfalse;
    }
    rtrue;
];
[ TableBlankOutRow tab j k;
    if (tab==0) return RunTimeProblem(RTP_TABLE_NOTABLE, tab);
    for (k=1:k<=tab-->0:k++)
        ForceTableEntryBlank(tab, k, j);
];
[ TableBlankRows tab i j c;
    i = TableRows(tab); !print i, " rows^";
    for (j=1:j<=i:j++)
        if (TableRowIsBlank(tab, j)) c++;
    !print c, " blank^";
    return c;
];
[ TableFilledRows tab;
    return TableRows(tab) - TableBlankRows(tab);
];
[ TableBlankRow tab i j;
    i = TableRows(tab);
    for (j=1:j<=i:j++)
        if (TableRowIsBlank(tab, j)) return j;
    RunTimeProblem(RTP_TABLE_NOMOREBLANKS, tab);
    return i;
];
```

§15. Random Row. `TableRandomRow(T)` chooses a random non-blank row in `T`.

```
[ TableRandomRow tab i j k;
    i = TableRows(tab);
    j = TableFilledRows(tab);
    if (j==0) return RunTimeProblem(RTP_TABLE_NOROWS, tab);
    if (j>1) j = random(j);
    for (k=1:k<=i:k++) {
        if (TableRowIsBlank(tab, k) == false) j--;
        if (j==0) return k;
    }
];
```

§**16. Swap Rows.** `TableSwapRows(T, R1, R2)` exchanges rows `R1` and `R2`.

```
[ TableSwapRows tab i j k l v1 v2;
    if (i==j) return;
    l = tab-->0;
    for (k=1:k<=l:k++) {
        v1 = (tab-->k)-->(i+COL_HSIZE);
        v2 = (tab-->k)-->(j+COL_HSIZE);
        (tab-->k)-->(i+COL_HSIZE) = v2;
        (tab-->k)-->(j+COL_HSIZE) = v1;
        if ((v1 == TABLE_NOVALUE) || (v2 == TABLE_NOVALUE))
            TableSwapBlankBits(tab, i, j, k);
    }
];
```

§**17. Compare Rows.** `TableCompareRows(T, C, R1, R2, D)` returns:

(a) +1 if the entry at row R1 of column C is > the entry at row R2,
(b) 0 if they are equal, and
(c) −1 if entry at R1 < entry at R2.

When $D = +1$, a blank value is greater than all other values, so that in an ascending sort the blanks come last; when $D = -1$, a blank value is less than all others, so that once again blanks are last. Finally, a wholly blank row is always placed after a row in which the entry in C is blank but where other entries are not.

```
[ TableCompareRows tab col row1 row2 dir val1 val2 bl1 bl2;
    if (col >= 100) col=TableFindCol(tab, col, false);
    val1 = (tab-->col)-->(row1+COL_HSIZE);
    val2 = (tab-->col)-->(row2+COL_HSIZE);
    if (val1 == TABLE_NOVALUE) bl1 = CheckTableEntryIsBlank(tab,col,row1);
    if (val2 == TABLE_NOVALUE) bl2 = CheckTableEntryIsBlank(tab,col,row2);
    if ((val1 == val2) && (bl1 == bl2)) {
        if (val1 ~= TABLE_NOVALUE) return 0;
        if (bl1 == false) return 0;
        ! The two entries are both blank:
        if (TableRowIsBlank(tab, row1)) {
            if (TableRowIsBlank(tab, row2)) return 0;
            return -1*dir;
        }
        if (TableRowIsBlank(tab, row2)) return dir;
        return 0;
    }
    if (bl1) return -1*dir;
    if (bl2) return dir;
    if (((tab-->col)-->1) & TB_COLUMN_SIGNED) {
        if (val1 > val2) return 1;
        return -1;
    } else {
        if (UnsignedCompare(val1, val2) > 0) return 1;
        return -1;
    }
];
```

§18. Move Row Down.

```
[ TableMoveRowDown tab r1 r2 rx k l m v f;
    if (r1==r2) return;
    l = tab-->0;
    for (k=1:k<=l:k++) {
        f = false;
        m = (tab-->k)-->(r1+COL_HSIZE);
        if (m == TABLE_NOVALUE) f = true;
        for (rx=r1:rx<r2:rx++) {
            v = (tab-->k)-->(rx+COL_HSIZE+1);
            (tab-->k)-->(rx+COL_HSIZE) = v;
            if (v == TABLE_NOVALUE) f = true;
        }
        (tab-->k)-->(r2+COL_HSIZE) = m;
        if (f) TableMoveBlankBitsDown(tab, r1, r2, k);
    }
];
```

§19. Shuffle. `TableShuffle(T)` sorts `T` into random row order.

```
[ TableShuffle tab i j k;
    k = TableRows(tab);
    for (i=2:i<=k:i++) TableSwapRows(tab, i, random(i));
    TableMoveBlanksToBack(tab, 1, k);
];
```

§20. Next Row. `TableNextRow(T, C, R, D)` is used when scanning through a table in order of the values in column `C`: ascending order if `D = 1`, descending if `D = -1`. The current position is row `R` of column `C`, or `R = 0` if we have not yet found the first row. The return value is the row number for the next value, or 0 if we are already at the final value. Note that if there are several equal values in the column, they will be run through in turn, in order of their physical row numbers - ascending if `D = 1`, descending if `D = -1`, so that using the routine with `D = -1` always produces the exact reverse ordering from using it with `D = 1` and the same parameters. Rows with blank entries in `C` are skipped.

```
for (R=TableNextRow(T,C,0,D): R : R=TableNextRow(T,C,R,D)) ...
```

will perform a loop of valid row numbers in order of column `C`.

```
[ TableNextRow tab col row dir i k val v dv min_dv min_at signed_arithmetic f;
    if (col >= 100) col=TableFindCol(tab, col, false);
    signed_arithmetic = ((tab-->col)-->1) & TB_COLUMN_SIGNED;
    #Iftrue (WORDSIZE == 2);
    if (row == 0) {
        if (signed_arithmetic) {
            if (dir == 1) val = $8000; else val = $7fff;
        } else {
            if (dir == 1) val = 0; else val = $ffff;
        }
    } else val = (tab-->col)-->(row+COL_HSIZE);
    if (signed_arithmetic) min_dv = $7fff; else min_dv = $ffff;
    #ifnot; ! WORDSIZE == 4
    if (row == 0) {
        if (signed_arithmetic) {
```

```
            if (dir == 1) val = $80000000; else val = $7fffffff;
        } else {
            if (dir == 1) val = 0; else val = $ffffffff;
        }
    } else val = (tab-->col)-->(row+COL_HSIZE);
    if (signed_arithmetic) min_dv = $7fffffff; else min_dv = $ffffffff;
    #endif;
    k = TableRows(tab);
    if (dir == 1) {
        for (i=1:i<=k:i++) {
            v = (tab-->col)-->(i+COL_HSIZE);
            if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,i)))
                continue;
            dv = dir*v;
            if (signed_arithmetic)
            f = (((dv > dir*val) || ((v == val) && (i>row))) &&
                (dv < min_dv));
            else
            f = (((UnsignedCompare(dv, dir*val) > 0) || ((v == val) && (i>row))) &&
                (UnsignedCompare(dv, min_dv) < 0));
            if (f) { min_dv = dv; min_at = i; }
        }
    } else {
        for (i=k:i>=1:i--) {
            v = (tab-->col)-->(i+COL_HSIZE);
            if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,i)))
                continue;
            dv = dir*v;
            if (signed_arithmetic)
            f = (((dv > dir*val) || ((v == val) && (i<row))) &&
                (dv < min_dv));
            else
            f = (((UnsignedCompare(dv, dir*val) > 0) || ((v == val) && (i<row))) &&
                (UnsignedCompare(dv, min_dv) < 0));
            if (f) { min_dv = dv; min_at = i; }
        }
    }
    return min_at;
];
```

§21. Move Blanks to Back.

```
[ TableMoveBlanksToBack tab fromrow torow i fbl lnbl blc;
    if (torow < fromrow) return;
    fbl = 0; lnbl = 0;
    for (i=fromrow: i<=torow: i++)
        if (TableRowIsBlank(tab, i)) {
            if (fbl == 0) fbl = i;
            blc++;
        } else {
            lnbl = i;
        }
    if ((fbl>0) && (lnbl>0) && (fbl < lnbl)) {
        TableMoveRowDown(tab, fbl, lnbl); ! Move first blank just past last nonblank
        TableMoveBlanksToBack(tab, fbl, lnbl-1);
    }
    return torow-blc; ! Final non-blank row
];
```

§22. Sort. This is really only a front-end: it calls the sorting code at "Sort.i6t".

```
[ TableSort tab col dir test_flag algorithm i j k f;
    for (i=1:i<=tab-->0:i++) {
        j = tab-->i; ! Address of column table
        if ((j-->1) & TB_COLUMN_DONTSORTME)
            return RunTimeProblem(RTP_TABLE_CANTSORT, tab);
    }
    if (col >= 100) col=TableFindCol(tab, col, false);
    k = TableRows(tab);
    k = TableMoveBlanksToBack(tab, 1, k);
    if (test_flag) {
        print "After moving blanks to back:^"; TableColumnDebug(tab, col);
    }
    SetSortDomain(TableSwapRows, TableCompareRows);
    SortArray(tab, col, dir, k, test_flag, algorithm);
    if (test_flag) {
        print "Final state:^"; TableColumnDebug(tab, col);
    }
];
```

§23. Print Table Name. NI fills this in: it's used to say the "table" kind of value.

```
[ PrintTableName T;
    switch(T) {
{-call:compile_print_table_names}
        default: print "** No such table **";
    }
];
```

§**24. Print Table to File.** This is how we serialise a table to an external file, though the writing is done by printing characters in the standard way; it's just that the output stream will be an external file rather than the screen when this routine is called.

```
[ TablePrint tab i j k row col v tc kov;
    for (i=1:i<=tab-->0:i++) {
        j = tab-->i; ! Address of column table
        if (((j-->1) & TB_COLUMN_CANEXCHANGE) == 0)
            rtrue;
    }
    k = TableRows(tab);
    k = TableMoveBlanksToBack(tab, 1, k);
    print "! ", (PrintTableName) tab, " (", k, ")^";
    for (row=1:row<=k:row++) {
        for (col=1:col<=tab-->0:col++) {
            tc = ((tab-->col)-->1) & TB_COLUMN_NUMBER;
            kov = NUMBER_TY;
            for (i=0: TC_KOVs-->i: i=i+3)
                if (TC_KOVs-->i == tc)
                    kov = TC_KOVs-->(i+1);
            v = (tab-->col)-->(row+COL_HSIZE);
            if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,row)))
                print "-- ";
            else {
                if (BlkValueWriteToFile(v, kov) == false) print v;
                print " ";
            }
        }
        print "^";
    }
    rfalse;
];
```

§**25. Read Table from File.** And this is how we unserialise again. It makes sense only on Glulx.

```
#ifdef TARGET_GLULX;
[ TableRead tab auxf row maxrow col ch v sgn dg j tc kov;
    for (col=1:col<=tab-->0:col++) {
        j = tab-->col; ! Address of column table
        if (((j-->1) & TB_COLUMN_CANEXCHANGE) == 0)
            return RunTimeProblem(RTP_TABLE_CANTSAVE, tab);
    }
    maxrow = TableRows(tab);
    !print maxrow, " rows available.^";
    for (row=1: row<=maxrow: row++) {
        TableBlankOutRow(tab, row);
    }
    for (row=1: row<=maxrow: row++) {
        !print "Reading row ", row, "^";
        ch = FileIO_GetC(auxf);
        if (ch == '!') {
            while (ch ~= -1 or 10 or 13) ch = FileIO_GetC(auxf);
            while (ch == 10 or 13) ch = FileIO_GetC(auxf);
```

```
    }
    for (col=1: col<=tab-->0: col++) {
        if (ch == -1) { row++; jump NoMore; }
        if (ch == 10 or 13) break;
        tc = ((tab-->col)-->1) & TB_COLUMN_NUMBER;
        kov = NUMBER_TY;
        for (j=0: TC_KOVs-->j: j=j+3)
            if (TC_KOVs-->j == tc)
                kov = TC_KOVs-->(j+1);
        !print "tc = ", tc, " kov = ", kov, "^";
        sgn = 1;
        if (ch == '-') {
            ch = FileIO_GetC(auxf);
            if (ch == -1) jump NotTable;
            if (ch == '-') { ch = FileIO_GetC(auxf); jump EntryDone; }
            sgn = -1;
        }
        if (((tab-->col)-->1) & TB_COLUMN_ALLOCATED)
            ForceTableEntryNonBlank(tab, col, row);
        !print "A";
        v = BlkValueReadFromFile(0, 0, -1, kov);
        if (v) {
            if (((tab-->col)-->1) & TB_COLUMN_ALLOCATED)
                v = BlkValueReadFromFile(TableLookUpEntry(tab, col, row),
                    auxf, ch, kov);
            else
                v = BlkValueReadFromFile(0, auxf, ch, kov);
            ch = 32;
        } else {
            dg = ch - '0';
            if ((dg < 0) || (dg > 9)) jump NotTable;
            v = dg;
            for (::) {
                ch = FileIO_GetC(auxf);
                dg = ch - '0';
                if ((dg < 0) || (dg > 9)) break;
                v = 10*v + dg;
            }
            v = v*sgn;
        }
        !print "v=", v, " ";
        if (((tab-->col)-->1) & TB_COLUMN_ALLOCATED == 0)
            TableLookUpEntry(tab, col, row, true, v);
        .EntryDone;
        !print "First nd is ", ch, "^";
        while (ch == 9 or 32) ch = FileIO_GetC(auxf);
    }
    while (ch ~= -1 or 10 or 13) {
        if ((ch ~= '-') && (((ch-'0')<0) || ((ch-'0')>9))) jump NotTable;
        if (ch ~= 9 or 32) jump WontFit;
        ch = FileIO_GetC(auxf);
    }
}
```

```
    .NoMore;
    while (ch == 9 or 32 or 10 or 13) ch = FileIO_GetC(auxf);
    if (ch == -1) return;
    .WontFit;
    return RunTimeProblem(RTP_TABLE_WONTFIT, tab);
    .NotTable;
    return RunTimeProblem(RTP_TABLE_BADFILE, tab);
];
#ENDIF; ! TARGET_GLULX
```

§**26. Print Rank.** The table of scoring ranks is a residue from the ancient times of early IF: it gets a tiny amount of special treatment here, even though I7 works tend not to use these now dated conventions.

```
[ PrintRank i j v;
#ifdef RANKING_TABLE;
    L__M(##Score, 3);
    j = TableRows(RANKING_TABLE);
    for (i=j:i>=1:i--)
        if (score >= TableLookUpEntry(RANKING_TABLE, 1, i)) {
            v = TableLookUpEntry(RANKING_TABLE, 2, i);
            if (v ofclass String) print (string) v;
            else v();
            ".";
        }
#endif;
    ".";
];
```

§**27. Debugging.** A routine to print the state of a table, for debugging purposes only.

```
[ TableColumnDebug tab col k i v;
    if (col >= 100) col=TableFindCol(tab, col, false);
    k = TableRows(tab);
    print "Table col ", col, ": ";
    for (i=1:i<=k:i++) {
        v = (tab-->col)-->(i+COL_HSIZE);
        if ((v == TABLE_NOVALUE) && (CheckTableEntryIsBlank(tab,col,i)))
            print "BLANK ";
        else print v, " ";
    }
    print "*^";
];
```

Sort Template B/sortt

Purpose

To sort arrays.

§**1. Storage.** We are required to use a stable sorting algorithm with very low, ideally zero, auxiliary storage requirement. Exchanges are generally slower than comparisons for the typical application (sorting tables, where entire rows must be exchanged whereas only entries in a single column need be compared).

In fact, we store some details in global variables for convenience and to avoid filling the stack with copies, but otherwise we will hardly need any auxiliary storage.

```
Global I7S_Tab; ! The array to be sorted, which can have almost any format
Global I7S_Col; ! The "column number" in the array, if any
Global I7S_Dir; ! The direction of sorting: ascending (1) or descending (-1)
Global I7S_Swap; ! The current routine for swapping two fields
Global I7S_Comp; ! The current routine for comparing two fields
#ifdef MEASURE_SORT_PERFORMANCE;
Global I7S_CCOUNT; Global I7S_CCOUNT2; Global I7S_XCOUNT; ! For testing only
#endif;
```

§**2. Front End.** To perform a sort, we first call `SetSortDomain` to declare the swap and compare functions to be used, and then call `SortArray` actually to sort. (It would be nice to combine these in a single call, but I6 allows a maximum of 7 call arguments for a routine, and that would make 8.) These are the only two routines which should ever be called from outside of this template segment.

The swap and compare functions are expected to take two arguments, which are the field numbers of the fields being swapped or compared, where fields are numbered from 1. Comparison is like `strcmp`: it returns 0 on equality, and then is positive or negative according to which of the fields is greater in value.

```
[ SetSortDomain swapf compf;
    I7S_Swap = swapf;
    I7S_Comp = compf;
];
[ SortArray tab col dir size test_flag algorithm;
    I7S_Tab = tab;
    I7S_Col = col;
    I7S_Dir = dir;
    #ifdef MEASURE_SORT_PERFORMANCE;
    I7S_CCOUNT = 0;
    I7S_CCOUNT2 = 0;
    I7S_XCOUNT = 0;
    #endif;
    SortRange(0, size, algorithm);
    #ifdef MEASURE_SORT_PERFORMANCE;
    if (test_flag)
        print "Sorted array of size ", size, " with ", I7S_CCOUNT2, "*10000 + ", I7S_CCOUNT,
            " comparisons and ", I7S_XCOUNT, " exchanges^";
    #endif;
];
```

§**3. Sort Range.** This routine sorts a range of fields $x \le i < y$ within the array. Fields are numbered from 0. The supplied `algorithm` is an I6 routine to implement a particular sorting algorithm; if it is not supplied, then in-place merge sort is used by default.

```
[ SortRange x y algorithm;
    if (y - x < 2) return;
    if (algorithm) {
        (algorithm)(x, y);
    } else {
        InPlaceMergeSortAlgorithm(x, y);
    }
];
```

§**4. Comparison and Exchange.** These are instrumented versions of how to swap and compare fields; note that the swap and compare functions are expected to number the fields from 1, not from 0. (This is convenient both for tables and lists, where rows and entries respectively are both numbered from 1.) The only access which the sorting algorithms have to the actual data being sorted is through these routines.

```
[ CompareFields x y;
    #ifdef MEASURE_SORT_PERFORMANCE;
    I7S_CCOUNT++;
    if (I7S_CCOUNT == 10000) { I7S_CCOUNT = 0; I7S_CCOUNT2++; }
    #endif;
    return I7S_Dir*I7S_Comp(I7S_Tab, I7S_Col, x+1, y+1, I7S_Dir);
];
[ ExchangeFields x y;
    #ifdef MEASURE_SORT_PERFORMANCE;
    I7S_XCOUNT++;
    if (I7S_XCOUNT < 0) { print "XO^"; I7S_XCOUNT = 0; }
    #endif;
    return I7S_Swap(I7S_Tab, x+1, y+1);
];
```

§**5. 4W37 Sort.** We now present three alternative sorting algorithms.

The first is the one used in builds up to and including 4W37: note that this is not quite bubble sort, and that it is unstable. It is now no longer used, but is so short that we might as well keep it in the code base in case anyone needs to resurrect a very early I7 project.

```
[ OldSortAlgorithm x y
    f i j;
    if (y - x < 2) return;
    f = true;
    while (f) {
        f = false;
        for (i=x:i<y:i++)
            for (j=i+1:j<y:j++)
                if (CompareFields(i, j) > 0) {
                    ExchangeFields(i, j); f = true; break;
                }
    }
];
```

§**6. Insertion Sort.** A stable algorithm which has $O(n^2)$ running time and therefore cannot be used with large arrays, but which has good performance on nearly sorted tables, and which has very low overhead.

```
[ InsertionSortAlgorithm from to
    i j;
    if (to > from+1) {
        for (i = from+1: i < to: i++) {
            for (j = i: j > from: j--) {
                if (CompareFields(j, j-1) < 0)
                    ExchangeFields(j, j-1);
                else break;
            }
        }
    }
];
```

§**7. In-Place Mergesort.** A stable algorithm with $O(n \log n)$ running time, at some stack cost, and which is generally good for nearly sorted tables, but which is also complex and has some overhead. The code here mostly follows Thomas Baudel's implementation, which in turn follows the `C++` STL library.

```
[ InPlaceMergeSortAlgorithm from to
    middle;
    if (to - from < 12) {
        if (to - from < 2) return;
        InsertionSortAlgorithm(from, to);
        return;
    }
    middle = (from + to)/2;
    InPlaceMergeSortAlgorithm(from, middle);
    InPlaceMergeSortAlgorithm(middle, to);
    IPMS_Merge(from, middle, to, middle-from, to - middle);
];
[ IPMS_Lower from to val
    len half mid;
    len = to - from;
    while (len > 0) {
        half = len/2;
        mid = from + half;
        if (CompareFields(mid, val) < 0) {
            from = mid + 1;
            len = len - half -1;
        } else len = half;
    }
    return from;
];
[ IPMS_Upper from to val
    len half mid;
    len = to - from;
    while (len > 0) {
        half = len/2;
        mid = from + half;
        if (CompareFields(val, mid) < 0)
```

```
            len = half;
        else {
            from = mid + 1;
            len = len - half -1;
        }
    }
    return from;
];
[ IPMS_Reverse from to;
    while (from < to) {
        ExchangeFields(from++, to--);
    }
];
[ IPMS_Rotate from mid to
    n val shift p1 p2;
    if ((from==mid) || (mid==to)) return;
    IPMS_Reverse(from, mid-1);
    IPMS_Reverse(mid, to-1);
    IPMS_Reverse(from, to-1);
];
[ IPMS_Merge from pivot to len1 len2
    first_cut second_cut len11 len22 new_mid;
    if ((len1 == 0) || (len2 == 0)) return;
    if (len1+len2 == 2) {
        if (CompareFields(pivot, from) < 0)
        ExchangeFields(pivot, from);
        return;
    }
    if (len1 > len2) {
        len11 = len1/2;
        first_cut = from + len11;
        second_cut = IPMS_Lower(pivot, to, first_cut);
        len22 = second_cut - pivot;
    } else {
        len22 = len2/2;
        second_cut = pivot + len22;
        first_cut = IPMS_Upper(from, pivot, second_cut);
        len11 = first_cut - from;
    }
    IPMS_Rotate(first_cut, pivot, second_cut);
    new_mid = first_cut + len22;
    IPMS_Merge(from, first_cut, new_mid, len11, len22);
    IPMS_Merge(new_mid, second_cut, to, len1 - len11, len2 - len22);
];
```

Relations Template B/relt

Purpose

To manage run-time storage for relations between objects, and to find routes through relations and the map.

---

§**1. One To One Relations.** We provide routines to assert a 1-to-1 relation true, or to assert it false. The relation `rel` is represented by a property number, and the property in question is used to store the fact of a relationship: $O_1 \sim O_2$ if and only if `O1.rel == O2`.

There is no routine to test a 1-to-1 relation, since the predicate calculus code in NI simplifies propositions which test these into direct looking up of the property relation.

```
[ Relation_Now1to1 obj1 relation_property obj2 ol; ! Assert 1-1 true
    if (obj2) objectloop (ol provides relation_property)
        if (ol.relation_property == obj2) ol.relation_property = nothing;
    if (obj1) obj1.relation_property = obj2;
];
[ Relation_NowN1toV obj1 relation_property obj2; ! Assert 1-1 false
    if ((obj1) && (obj1.relation_property == obj2)) obj1.relation_property = nothing;
];
```

§**2. Symmetric One To One Relations.** Here the relation is used for both objects: $O_1 \sim O_2$ if and only if both `O1.relation_property == O2` and `O2.relation_property == O1`.

```
[ Relation_NowS1to1 obj1 relation_property obj2 ol; ! Assert symmetric 1-1 true
    if ((obj1 ofclass Object) && (obj1 provides relation_property) &&
        (obj2 ofclass Object) && (obj2 provides relation_property)) {
        if (obj1.relation_property) { (obj1.relation_property).relation_property = 0; }
        if (obj2.relation_property) { (obj2.relation_property).relation_property = 0; }
        obj1.relation_property = obj2; obj2.relation_property = obj1;
    }
];
[ Relation_NowSN1to1 obj1 relation_property obj2 ol; ! Assert symmetric 1-1 false
    if ((obj1 ofclass Object) && (obj1 provides relation_property) &&
        (obj2 ofclass Object) && (obj2 provides relation_property) &&
        (obj1.relation_property == obj2)) {
        obj1.relation_property = 0; obj2.relation_property = 0;
    }
];
```

§**3. Various To Various Relations.** Here the relation is represented by an array holding its metadata. Each object in the domain of the relation provides two properties, holding its left index and its right index. The index is its position in the left or right domain. For instance, suppose we relate things to doors, and there are five things in the world, two of which are doors; then the left indexes will range from 0 to 4, while the right indexes will range from 0 to 1. It's very likely that the doors will have different left and right indexes. (If the relation relates a given kind to itself, say doors to doors, then left and right indexes will always be equal.)

It is possible for either the left or right domain set to be an enumerated kind of value, where the I6 representation of values is 1, 2, 3, ..., N, where there are N possibilities. In that case we obtain the index simply by subtracting 1 in order to begin from 0. We mark the domain set as being a KOV rather than a kind of object by storing 0 instead of a property in the relevant part of the relation metadata: note that 0 is not a valid property number.

The structure for a relation consists of eight `-->` words, followed by a bitmap in which we store 16 bits in each `-->` word. (Yes, this is wasteful in Glulx, where `-->` words store 32 bits, but memory is not in short supply in Glulx and the total cost of relations is in practice small; we prefer to keep all the code involved simple.) The structure is precompiled by the NI compiler: we do not create new ones on the fly.

In the case of a symmetric various to various relation, we could in theory save memory once again by storing only the lower triangle of the bitmap, but the time and complexity overhead are not worth it. When asserting that $O_1 \sim O_2$ for a symmetric V-to-V, we also automatically assert that $O_2 \sim O_1$, thus maintaining the bitmap as a symmetric matrix; but in reading the bitmap, we look only at the lower triangle. This costs a little time, but has the advantage of allowing the route-finding routine for V-to-V to use the same code for symmetric and asymmetric relations.

If this all seems rather suboptimally programmed in order to reduce code complexity, I can only say that careless drafts here were the source of some extremely difficult bugs to find.

§**4. Equivalence Relations.** For every equivalence relation there is a corresponding function f such that $x \sim y$ if and only if $f(x) = f(y)$, where $f(x)$ is a number identifying the equivalence class of x. Rather than inefficiently storing a large relation bitmap (and then having a very complicated time updating it to keep the relation transitive), we store f: that is, for every object in the domain set, there is a property `prop` such that `O.prop` is the value $f(O)$.

```
[ Relation_NowEquiv obj1 relation_property obj2 big little;
    big = obj1.relation_property; little = obj2.relation_property;
    if (big == little) return;
    if (big < little) { little = obj1.relation_property; big = obj2.relation_property; }
    objectloop (obj1 provides relation_property)

                if (Relation_TestVtoV(obj1, vtov_structure, obj2)) {
                    if (x) { Relation_ShowRHeader(x); x=0; }
                    print "  ", (The) obj1, "  >=>  ";
                    (proutine2).call(obj2);
                    print "^";
                }
        }
        return;
    }
    if ((pr==0) && (pr2)) {
        for (obj1=1:obj1<=vtov_structure-->2:obj1++)
        objectloop (obj2 provides pr2) {
                if (Relation_TestVtoV(obj1, vtov_structure, obj2)) {
                    if (x) { Relation_ShowRHeader(x); x=0; }
                    print "  ";
                    (proutine1).call(obj1);
                    print "  >=>  ", (the) obj2, "^";
                }
        }
        return;
    }
    for (obj1=1:obj1<=vtov_structure-->2:obj1++)
        for (obj2=1:obj2<=vtov_structure-->VTOVS_RIGHT_DOMAIN_SIZE:obj2++)
            if (Relation_TestVtoV(obj1, vtov_structure, obj2)) {
                if (x) { Relation_ShowRHeader(x); x=0; }
                print "  ";
                (proutine1).call(obj1);
                print "  >=>  ";
                (proutine2).call(obj2);
                print "^";
        }
];
```

§7. Show One to One.

```
[ Relation_ShowOtoO relation_property sym x obj1 obj2;
    objectloop (obj1 provides relation_property) {
            obj2 = obj1.relation_property;
            if (sym && obj2 < obj1) continue;
            if (obj2 == 0) continue;
        if (x) { Relation_ShowRHeader(x); x=0; }
        print "  ", (The) obj1;
        if (sym) print "  ==  "; else print "  >=>  ";
        print (the) obj2, "^";
    }
];
```

§**8. Show Reversed One to One.** There's no such kind of relation as this: but the same code used to show 1-to-1 relations is also used to show various-to-1 relations, since the storage is the same. To show 1-to-various relations, we need a transposed form of the same code in which left and right are exchanged: this is it.

```
[ Relation_RShowOtoO relation_property sym x obj1 obj2;
    objectloop (obj1) {
        objectloop (obj2 provides relation_property) {
            if (obj2.relation_property ~= obj1) continue;
            if (x) { Relation_ShowRHeader(x); x=0; }
            print "  ", (The) obj1;
            print "  >=>  ";
            print (the) obj2, "^";
        }
    }
];
```

§**9. Show Equivalence.**

```
[ Relation_ShowEquiv relation_property obj1 obj2 v c somegroups;
    objectloop (obj1 provides relation_property)
        obj1.relation_property = -(obj1.relation_property);
    objectloop (obj1 provides relation_property) {
        if (obj1.relation_property < 0) {
            v = obj1.relation_property; c = 0;
            objectloop (obj2 has workflag2) give obj2 ~workflag2;
            objectloop (obj2 provides relation_property) {
                if (obj2.relation_property == v) {
                    give obj2 workflag2;
                    obj2.relation_property = -v;
                    c++;
                }
            }
            if (c>1) {
                somegroups = true;
                print "  { ";
                WriteListOfMarkedObjects(ENGLISH_BIT);
                print " }^";
            } else obj1.relation_property = v;
        }
    }
    objectloop (obj2 has workflag2) give obj2 ~workflag2;
    c = 0; objectloop (obj1 provides relation_property)
        if (obj1.relation_property < 0) { c++; give obj1 workflag2; }
    if (c == 0) return;
    if (somegroups) print "  and "; else print "  ";
    if (c < 4) { WriteListOfMarkedObjects(ENGLISH_BIT); print " in"; }
    else print c;
    if (c == 1) print " a";
    print " single-member group";
    if (c > 1) print "s";
    print "^";
    objectloop (obj1 provides relation_property)
```

```
        if (obj1.relation_property < 0)
            obj1.relation_property = -(obj1.relation_property);
];
```

§**10. Map Route-Finding.** The general problem we have to solve here is: given $x, y \in R$, where R is the set of rooms and we write $x \sim y$ if there is a map connection from x to y,

(i) find the smallest m such that there exist $x = r_1 \sim r_2 \sim ... \sim r_m = y \in R$, or determine that no such m exists, and

(ii) find d, the first direction to take from x to lead to r_2, or set $d = 0$ if no such path exists or if $m = 1$ so that $x = y$.

Thus a typical outcome might be either "a shortest path from the Town Square to the Hilltop takes 11 moves, starting by going northeast from the Town Square", or alternatively "there's no path from the Town Square to the Hilltop at all". Note that the length of the shortest path is unambiguous, but that there might be many alternative paths of this minimum length: we deliberately do not specify which path is chosen if so, and the two algorithms used below do not necessarily choose the same one.

Route-finding is not an easy operation in computation terms: the various algorithms available have theoretical running times which are easy (if sobering) to compute, but which are not in practice typical of what will happen, because they are quite sensitive to the map in question. Are all the rooms laid out in a long line? Are there clusters of connected rooms like islands? Are there dense clumps of interconnecting rooms? Are there huge but possibly time-saving loops? And so on. Overhead is also important. We present a choice of two algorithms: the "fast" one has a theoretical running time of $O(n^3)$, where n is the number of rooms, whereas the "slow" one runs in $O(n^2)$, yet in practice the fast one easily outperforms the slow on typical heavy-use cases with large maps.

The other issue is memory usage: we essentially have to strike a bargain between speed and memory overhead. Our "slow" algorithm needs only $O(n)$ storage, whereas our "fast" algorithm needs $O(n^2)$, and this is very significant in the Z-machine where array space is in desperately short supply and where, if $n > 50$ or so, the user is already likely to be fighting for the last few bytes in readable memory.

The user is therefore offered the choice, by selecting the use options "Use fast route-finding" and "Use slow route-finding": and the defaults, if neither option is explicitly set, are fast on Glulx and slow on the Z-machine. If both use options are explicitly set – which might happen due to a disagreement between extensions – "fast" wins.

```
#ifndef FAST_ROUTE_FINDING;
#ifndef SLOW_ROUTE_FINDING;
#ifdef TARGET_GLULX;
Constant FAST_ROUTE_FINDING;
#ifnot;
Constant SLOW_ROUTE_FINDING;
#endif;
#endif;
#endif;
```

§**11. Cache Control.** We provide code to enable our route-finding algorithms to cache their partial results from one usage to the next (though at present only the "fast" algorithm does this). The difficulty here is that the result of a route search depends on three things, any of which may change:

(a) which subset of rooms we are route-finding through;
(b) which subset of doors we are allowing ourselves to use; and
(c) the current map connections between rooms.

We keep track of (c) by watching for calls to `SignalMapChange()` from the routines in "WorldModel.i6t" which alter the map. (a) and (b), however, require tracking from call to call what the current subset of rooms and doors is. (It is not sufficient to remember the criteria used last time and this time, because circumstances could have changed such that the criteria produce a different outcome. For instance, searching through lighted rooms and using unlocked doors will produce a different result if a door has been locked or unlocked since last time, or if a room has become lighted or not.) We store the set of applicable rooms and doors by enumerating them in the property `room_index` and by the flags in the `DoorRoutingViable` array respectively.

```
Constant NUM_DOORS = {-value:instance_count_for_kind(kind_door)};
Constant NUM_ROOMS = {-value:instance_count_for_kind(kind_room)};

Array DoorRoutingViable -> NUM_DOORS+1;

Global map_has_changed = true;
Global last_filter; Global last_use_doors;

[ SignalMapChange; map_has_changed = true; ];

[ MapRouteTo from to filter use_doors count  oy oyi ds;
    if (from == nothing) return nothing;
    if (to == nothing) return nothing;
    if (from == to) return nothing;
    if ((filter) && (filter(from) == 0)) return nothing;
    if ((filter) && (filter(to) == 0)) return nothing;
    if ((last_filter ~= filter) || (last_use_doors ~= use_doors)) map_has_changed = true;
    oyi = 0;
    objectloop (oy has mark_as_room) {
        if ((filter == 0) || (filter(oy))) {
            if (oy.room_index == -1) map_has_changed = true;
            oy.room_index = oyi++;
        } else {
            if (oy.room_index >= 0) map_has_changed = true;
            oy.room_index = -1;
        }
    }
    oyi = 0;
    objectloop (oy ofclass K4_door) {
        ds = false;
        if ((use_doors & 2) ||
            (oy has open) || ((oy has openable) && (oy hasnt locked))) ds = true;
        if (DoorRoutingViable->oyi ~= ds) map_has_changed = true;
        DoorRoutingViable->oyi = ds;
        oyi++;
    }
    if (map_has_changed) {
        #ifdef FAST_ROUTE_FINDING; ComputeFWMatrix(filter, use_doors); #endif;
        map_has_changed = false; last_filter = filter; last_use_doors = use_doors;
    }
    #ifdef FAST_ROUTE_FINDING;
    if (count) return FastCountRouteTo(from, to, filter, use_doors);
```

```
    return FastRouteTo(from, to, filter, use_doors);
    #ifnot;
    if (count) return SlowCountRouteTo(from, to, filter, use_doors);
    return SlowRouteTo(from, to, filter, use_doors);
    #endif;
];
```

§**12. Fast Route-Finding.** The following is a form of Floyd's adaptation of Warshall's algorithm for finding the transitive closure of a directed graph.

We need to store a matrix which for each pair of rooms R_i and R_j records a_{ij}, the shortest path length from R_i to R_j or 0 if no path exists, and also d_{ij}, the first direction to take on leaving R_i along a shortest path to R_j, or 0 if no path exists. For the sake of economy we represent the directions as their instance counts (numbered from 0 in order of creation), not as their direction object values, and then store a single word for each pair (i, j): we store $d_{ij} + Da_{ij}$. This restricts us on a signed 16-bit virtual machine, and with the conventional set of $D = 12$ directions, to the range $0 \le a_{ij} \le 5461$, that is, to path lengths of 5461 steps or fewer. A work of IF with 5461 rooms will not fit in the Z-machine anyway: such a work would be on Glulx, which is 32-bit, and where $0 \le a_{ij} \le 357,913,941$.

We begin with $a_{ij} = 0$ for all pairs except where there is a viable map connection between R_i and R_j: for those we set $a_{ij} = 1$ and d_{ij} equal to the direction of that map connection.

Following Floyd and Warshall we test if each known shortest path R_x to R_y can be used to shorten the best known path from R_x to anywhere else: that is, we look for cases where $a_{xy} + a_{yj} < a_{xj}$, since those show that going from R_x to R_j via R_y takes fewer steps than going directly. See for instance Robert Sedgewick, *Algorithms* (1988), chapter 32.

The trouble with the Floyd-Warshall algorithm is not so much that it takes in principle $O(n^3)$ time to construct the matrix: it does, but the coefficient is low, and in the early stages of the outer loop the fact that the vertex degree is at most D and usually much lower helps to reduce the work further. The trouble is that there is no way to compute only the part of the matrix we want: we have to have the entire thing, and that means storing n^2 words of data, by which point we have computed not only the fastest route from R_x to R_y but also the fastest route from anywhere to anywhere else. Even when the original map is sparse, the Floyd-Warshall matrix is not, and it is difficult to store in any very compressed way without greatly increasing the complexity of the code. This is why we cache the results: we might as well, since we had to build the entire memory structure anyway, and it means the time expense is only paid once (or once for every time the state of doors and map connections changes), and the cache is useful for all future routes whatever their endpoints.

```
#ifdef FAST_ROUTE_FINDING;
Array FWMatrix --> NUM_ROOMS*NUM_ROOMS;
[ FastRouteTo from to filter use_doors diri i dir oy;
    diri = (FWMatrix-->(from.room_index*NUM_ROOMS + to.room_index))%No_Directions;
    objectloop (dir ofclass K3_direction) {
        if (i == diri) return dir;
        i++;
    }
    return nothing;
];
[ FastCountRouteTo from to filter use_doors oy;
    return (FWMatrix-->(from.room_index*NUM_ROOMS + to.room_index))/No_Directions;
];
```

§**13.** And here is the FW-matrix:

```
[ ComputeFWMatrix filter use_doors  oy ox oj axy ayj axj dir diri nd row;
    objectloop (oy has mark_as_room) if (oy.room_index >= 0)
        objectloop (ox has mark_as_room) if (ox.room_index >= 0)
            FWMatrix-->(oy.room_index*NUM_ROOMS + ox.room_index) = 0;
    objectloop (oy has mark_as_room) if (oy.room_index >= 0) {
        row = (oy.IK_1)*No_Directions;
        for (diri=0: diri<No_Directions: diri++) {
            ox = Map_Storage-->(row+diri);
            if ((ox) && (ox has mark_as_room) && (ox.room_index >= 0)) {
                FWMatrix-->(oy.room_index*NUM_ROOMS + ox.room_index) = No_Directions + diri;
                continue;
            }
            if ((ox ofclass K4_door) && (DoorRoutingViable->(ox.IK_4))) {
                @push location; location = oy;
                ox = ox.door_to();
                @pull location;
                if ((ox) && (ox has mark_as_room) && (ox.room_index >= 0)) {

§**14. Slow Route-Finding.** The alternative algorithm, used when only $O(n)$ memory is available, computes only some of the shortest paths leading to R_y, and is not cached – both because the storage is likely to be reused often by other searches and because there is little gain from doing so, given that a subsequent search with different endpoints will not benefit from the results of this one. On the other hand, to call it "slow" is a little unfair. It is somewhat like Prim's algorithm for finding a minimum spanning tree, rooted at R_y, and grows the tree outward from R_y until either R_x is reached – in which case we stop immediately – or the (directed) component containing R_y has been exhausted – in which case R_x, which must lie outside this, can have no path to R_y. In principle, the running time is $O(dn^2)$, where $d \leq D$ is the maximum vertex degree and n is the number of rooms in the component containing R_y: in practice the degree is often much less than 12, while the algorithm finishes quickly in cases where R_y is relatively isolated and inaccessible or where a shortish route does exist, and those are very common cases in typical usage. There will be circumstances where, because few routes need to be found and because of the shape of the map, the "slow" algorithm will outperform the "fast" one: this is why the user is allowed to control which algorithm is used.

For each room R_z, the property `vector` stores the direction object of the way to go to its parent room in the tree rooted at R_y. Thus if the algorithm succeeds in finding a route from R_x to R_y then we generate the route by starting at R_x and repeatedly going in the `vector` direction from where we currently stand until we reach R_y. Since every room needs a `vector` value, this requires n words of storage. (The `vector` values store only enough of the minimal spanning tree to go upwards through the tree, but that's the only way we need to traverse it.)

The method can be summed up thus:

(a) Begin with every vector blank except that of R_y, the destination.
(b) Repeatedly: For every room in the domain set, try each direction: if this leads to a room whose vector was determined on the last round (*not* on this one, as that may be a suboptimal route), set the vector to point to that room.
(c) Stop as soon as the vector from the origin is set, or when a round happens in which no further vectors are found: in which case, we have completely explored the component of the map from which the destination can be reached, and the origin isn't in it, so we can return "no".

To prove the correctness of this, we show inductively that after round n we have set the `vector` for every room having a shortest path to R_y of length n, and that every `vector` points to a room having a `vector` in the direction of the shortest path from there to R_y.

```

§**15. Relation Route-Finding.** The general problem we have to solve here is: given $x, y \in D$, where $\sim$ is a relation on a domain set D of objects,

(i) find the smallest n such that there exist $x = r_1 \sim r_2 \sim ... \sim r_n = y \in D$ such that $r_i \sim r_{i+1}$, or determine that no such n exists, and if so

(ii) find a value of r_2 in such a "route" between x and y, or set $r_2 = 0$ if $x = y$ so that $n = 1$.

While in general a relation can have different left and right domains (a relation between doors and rooms, say), route-finding on those relations is unlikely to be very useful, so is discouraged. (In the case of doors and rooms, a route could never be longer than 1 step, since no object is both a door and a room, for instance.) The "fast" V-to-V algorithm requires D to have the same left and right domains; NI compiles the memory caches for V-to-V relations to force any cases with different domains into using the "slow" algorithm.

`MAX_ROUTE_LENGTH` is used simply as a sanity check to prevent hangs if something should go wrong, for instance if the property of a 1-to-V relation has been modified by some third-party code in such a way that it loses its defining invariant.

```
Constant MAX_ROUTE_LENGTH = {-value:NUMBER_CREATED(world_object)} + 32;

[ RelationRouteTo relation from to count  relation_data relation_kind rv obj i;
    if (count) {
        if (from == nothing) return -1;
        if (to == nothing) return -1;
        if (relation == 0) return -1;
    } else {
        if (from == nothing) return nothing;
        if (to == nothing) return nothing;
        if (relation == 0) return nothing;
    }
    if (from == to) return nothing;
    relation_data = relation_metadata-->(3*relation);
    relation_kind = relation_metadata-->(3*relation+1);
    if (relation_kind == Relation_ByRoutine or Relation_Implicit) {
        RunTimeProblem(RTP_ROUTELESS);
        return nothing;
    }
    if (relation_data == 0) return nothing;
    switch(relation_kind) {
        Relation_OtoO: rv = OtoVRelRouteTo(relation_data, from, to);
        Relation_VtoO: rv = VtoORelRouteTo(relation_data, from, to);
        Relation_OtoV: rv = OtoVRelRouteTo(relation_data, from, to);
        default: return VtoVRelRouteTo(relation_data, from, to, count);
    }
    if (count) {
        if (rv == nothing) return -1;
        i = 0; obj = from;
        while ((obj ~= to) && (i<=MAX_ROUTE_LENGTH)) { i++; obj = obj.vector; }
        return i;
    }
    return rv;
];
```

§**16. One To Various Route-Finding.** Here we can immediately determine, given y, the unique y' such that $y' \sim y$, so finding a path from x to y is a matter of following the only path leading to y and seeing if it ever passed through x; thus the running time is $O(n)$, where n is the size of the domain. It would be pointless to cache this.

Note that we can assume here that $x \neq y$, or rather, that `from ~= to`, because that case has already been taken care of.

```
[ OtoVRelRouteTo relation_property from to previous;
    while ((to) && (to provides relation_property) && (to.relation_property)) {
        previous = to.relation_property;
        previous.vector = to;
        if (previous == from) return to;
        to = previous;
    }
    return nothing;
];
```

§**17. Various To One Route-Finding.** This time the simplifying assumption is that, given x, we can immediately determine the unique x' such that $x \sim x'$, so it suffices to follow the only path forwards from x and see if it ever reaches y. The routine is not quite a mirror image of the one above, because both have the same return requirements: we have to ensure that the `vector` properties lay out the path, and also return the next step after x.

```
[ VtoORelRouteTo relation_property from to next  start;
    start = from;
    while ((from) && (from provides relation_property) && (from.relation_property)) {
        next = from.relation_property;
        from.vector = next;
        if (from == to) return start.vector;
        from = next;
    }
    return nothing;
];
```

§**18. Slow Various To Various Route-Finding.** Now there are no simplifying assumptions and the problem is essentially the same as the one solved for route-finding in the map, above. Once again we present two different algorithms: first, a form of Prim's algorithm for minimal spanning trees. Note that, whereas this algorithm was not always so "slow" for the map – because of the fairly low vertex degrees involved, i.e., because most rooms had few connections to other rooms – here the relation might well be almost complete, with almost all the objects related to each other, and then the algorithm will indeed be "slow". So it is likely that the "fast" algorithm will always be better, if the memory can be spared for it.

We use the fast algorithm for a given relation if and only if the NI compiler has allocated the necessary cache memory; the two use options above, for map route-finding, don't control this.

```
[ VtoVRelRouteTo vtov_structure from to count obj obj2 related progressed left_ix pr2 i;
    if (vtov_structure-->VTOVS_CACHE)
        return FastVtoVRelRouteTo(vtov_structure, from, to, count);
    left_ix = vtov_structure-->VTOVS_LEFT_INDEX_PROP;
    pr2 = vtov_structure-->VTOVS_RIGHT_INDEX_PROP;
    objectloop (obj ofclass Object && obj provides vector) obj.vector = 0;
    to.vector = 1;
    while (true) {
```

```
        progressed = false;
        objectloop (obj ofclass Object && obj provides left_ix)
            if (obj.vector == 0) {
                objectloop (obj2 ofclass Object && obj2 provides pr2 && obj2.vector > 0) {
                    if (Relation_TestVtoV(obj, vtov_structure, obj2)) {
                        obj.vector = obj2 | WORD_HIGHBIT;
                        progressed = true;
                        continue;
                    }
                }
            }
        objectloop (obj ofclass Object && obj provides left_ix)
            obj.vector = obj.vector &~ WORD_HIGHBIT;
        if (from.vector) break;
        if (progressed == false) break;
    }
    if (count) {
        if (from.vector == nothing) return -1;
        i = 0; obj = from;
        while ((obj ~= to) && (i<=MAX_ROUTE_LENGTH)) { i++; obj = obj.vector; }
        return i;
    }
    return from.vector;
];
```

§**19. Fast Various To Various Route-Finding.** Now, as above, a form of the Floyd-Warshall algorithm. The matrix is here stored in the cache of memory pointed to in the V-to-V relation structure. We are unable to combine a_{ij} and d_{ij} into a single cell of memory, so in fact we store two separate matrices: one for a_{ij} (this is `cache` below), the other for n_{ij}, where n_{ij} is the next object in the shortest path from O_i to O_j (this is `cache2` below).

Where $n < 256$ a shortest path must be such that $a_{ij} \leq 255$, so can be stored in a single byte, and we similarly store n_{ij} as the index of the object rather than the object value itself: the index ranges from 0 to $n-1$, so that $0 \leq n_{ij} < 255$ and we can use $n_{ij} = 255$ as a sentinel value meaning "no path". Although the reconversion of n_{ij} back into a valid object value takes a little time, it is only $O(n)$, and of course we know n is relatively small; and in this way we reduce the storage overhead to only n^2 bytes.

Where $n \geq 256$, we resign ourselves to storing two words for each pair (i, j), making $2n^2$ bytes of storage on the Z-machine and $4n^2$ bytes of storage on Glulx, but lookup of a cached result is slightly faster.

        }
    }
    if (count) return -1;
    return nothing;
];
```

Figures Template B/figst

Purpose

To display figures and play sound effects.

§**1. Resource Usage.** We record whether pictures or sounds have been used before by storing single byte flags in the following array. (The extra 5 values allow for the fact that it can be legal to use low undeclared sound effect resource numbers in the Z-machine for short beeps, though this is deprecated in I7.)

Pictures and sounds are identified within blorb archives by resource ID numbers which count upwards from 1 in order of creation, but can mix pictures and sounds freely. (For instance, 1 might be a picture, 2 and 3 sound effects, then 4 a picture again, etc.) ID number 1 is in fact always a picture: it means the cover art, and is the I6 representation of the value "figure of cover".

```
Array ResourceUsageFlags ->
    ({-value:NUMBER_CREATED(blorb_figure)}+{-value:NUMBER_CREATED(blorb_sound)}+5);
```

§**2. Figures.**

```
[ DisplayFigure resource_ID one_time;
    if ((one_time) && (ResourceUsageFlags->resource_ID)) return;
    ResourceUsageFlags->resource_ID = true;
    print "^"; VM_Picture(resource_ID); print "^";
];
```

§**3. Sound Effects.**

```
[ PlaySound resource_ID one_time;
    if (resource_ID == 0) return; ! The "silence" non-sound effect
    if ((one_time) && (ResourceUsageFlags->resource_ID)) return;
    ResourceUsageFlags->resource_ID = true;
    VM_SoundEffect(resource_ID);
];
```

IndexedText Template B/inxt

Purpose

Code to support the indexed text kind of value.

---

§**1. Head.** As ever: if there is no heap, there are no indexed texts.

```
#IFDEF MEMORY_HEAP_SIZE; ! Will exist if any use is made of indexed texts
```

§**2. Character Set.** On the Z-machine, we use the 8-bit ZSCII character set, stored in bytes; on Glulx, we use the opening 16-bit subset of Unicode (which though only a subset covers almost all letter forms used on Earth), stored in two-byte half-words.

The Z-machine does have very partial Unicode support, but not in a way that can help us here. It is capable of printing a wide range of Unicode characters, and on a good interpreter with a good font (such as Zoom for Mac OS X, using the Lucida Grande font) can produce many thousands of glyphs. But it is not capable of printing those characters into memory rather than the screen, an essential technique for indexed texts: it can only write each character to a single byte, and it does so in ZSCII. That forces our hand when it comes to choosing the indexed-text character set.

```
#IFDEF TARGET_ZCODE;
Constant IT_Storage_Flags = BLK_FLAG_MULTIPLE;
Constant ZSCII_Tables;
#IFNOT;
Constant IT_Storage_Flags = BLK_FLAG_MULTIPLE + BLK_FLAG_16_BIT;
Constant Large_Unicode_Tables;
#ENDIF;
{-segment:UnicodeData.i6t}
{-segment:Char.i6t}
```

§**3. KOV Support.** See the "BlockValues.i6t" segment for the specification of the following routines.

```
[ INDEXED_TEXT_TY_Support task arg1 arg2 arg3;
    switch(task) {
        CREATE_KOVS:     return INDEXED_TEXT_TY_Create(arg1);
        CAST_KOVS:       return INDEXED_TEXT_TY_Cast(arg1, arg2, arg3);
        DESTROY_KOVS:    rfalse;
        PRECOPY_KOVS:    rfalse;
        COPY_KOVS:       rfalse;
        COMPARE_KOVS:    return INDEXED_TEXT_TY_Compare(arg1, arg2);
        READ_FILE_KOVS:  if (arg3 == -1) rtrue;
                         return INDEXED_TEXT_TY_ReadFile(arg1, arg2, arg3);
        WRITE_FILE_KOVS: return INDEXED_TEXT_TY_WriteFile(arg1);
    }
];
```

§**4. Creation.** Indexed texts are are simply "C strings", that is, the array entries in the block are a sequence of character codes terminated by the character code 0, which is free for this purpose in both ZSCII and Unicode. Since none of the data in an indexed-text is a pointer back onto the heap, it can all freely be bitwise copied or forgotten, which is why we need do nothing special to copy or destroy an indexed text.

Note that a freshly allocated block contains 0s in its data section, so its array entries already form a null-terminated empty text.

```
[ INDEXED_TEXT_TY_Create opcast x;
    x =  BlkAllocate(32, INDEXED_TEXT_TY, IT_Storage_Flags);
    if (opcast) INDEXED_TEXT_TY_Cast(opcast, TEXT_TY, x);
    return x;
];
```

§**5. Casting.** In general computing, "casting" is the process of translating data in one type into semantically equivalent data in another: for instance, translating the integer 1 into the floating point number 1.0, which will have an entirely different binary representation but has roughly the same meaning.

Here we are given a snippet – a word-selection of the player's command – or an ordinary text, and must cast it into an indexed text. In each case, what we do is simply to print out the value we have, but with the output stream set to memory rather than the screen. That gives us the character by character version, neatly laid out in an array, and all we have to do is to copy it into the indexed text and add a null termination byte.

What complicates things is that the two virtual machines handle printing to memory quite differently, and that the original text has unpredictable length. We are going to try printing it into the array `IT_MemoryBuffer`, but what if the text is too big? Disastrously, the Z-machine simply writes on in memory, corrupting all subsequent arrays and almost certainly causing the story file to crash soon after. There is nothing we can do to predict or avoid this, or to repair the damage: this is why the Inform documentation warns users to be wary of using indexed text with large strings in the Z-machine, and advises the use of Glulx instead. Glulx does handle overruns safely, and indeed allows us to dynamically allocate memory as necessary so that we can always avoid overruns entirely.

In either case, though, it's useful to have `IT_MemoryBufferSize`, the size of the temporary buffer, large enough that it will never be overrun in ordinary use. This is controllable with the use option "maximum indexed text length".

The following routine is not as messy as it looks: it is complicated by the fact that the Z-machine and Glulx (a) use different formats when printing text to memory, and (b) handle overruns differently, as explained above.

```
#ifndef IT_MemoryBufferSize;
Constant IT_MemoryBufferSize = 512;
#endif;

Constant IT_Memory_NoBuffers = 2;

#ifndef IT_Memory_NoBuffers;
Constant IT_Memory_NoBuffers = 1;
#endif;

#ifdef TARGET_ZCODE;

            if (i ~= 0) {
                if (freebuff) VM_FreeMemory(freebuff);
                freebuff = i;
                buff = i;
                RawBufferSize = news/4;
                jump RetryWithLargerBuffer;
            }
            ! Memory allocation refused: all we can do is to truncate the text
            len = RawBufferSize-1;
        }
        offs = 0;
        buff-->(len) = 0;
        #endif;
        len++;
    }
    IT_cast_nesting--;
    if (indt == 0) {
        indt = BlkAllocate(len+1, INDEXED_TEXT_TY, IT_Storage_Flags);
        if (indt == 0) jump Failed;
    } else {
        if (BlkValueSetExtent(indt, len+1, 1) == false) { indt = 0; jump Failed; }
    }
    #ifdef TARGET_ZCODE;
    for (i=0:i<=len:i++) BlkValueWrite(indt, i, buff->(i+offs));
    #ifnot;
    for (i=0:i<=len:i++) BlkValueWrite(indt, i, buff-->(i+offs));
    #endif;
    .Failed;
    if (freebuff) VM_FreeMemory(freebuff);
    return indt;
];
```

§**6. Comparison.** This is more or less `strcmp`, the traditional C library routine for comparing strings.

```
[ INDEXED_TEXT_TY_Compare indtleft indtright pos ch1 ch2 dsizeleft dsizeright;
    dsizeleft = BlkValueExtent(indtleft);
    dsizeright = BlkValueExtent(indtright);
    for (pos=0:(pos<dsizeleft) && (pos<dsizeright):pos++) {
        ch1 = BlkValueRead(indtleft, pos);
        ch2 = BlkValueRead(indtright, pos);
        if (ch1 ~= ch2) return ch2-ch1;
        if (ch1 == 0) return 0;
    }
    if (pos == dsizeleft) return 1;
    return -1;
];
[ INDEXED_TEXT_TY_Distinguish indtleft indtright;
    if (INDEXED_TEXT_TY_Compare(indtleft, indtright) == 0) rfalse;
    rtrue;
];
```

§**7. Printing.** Unicode is not the native character set on Glulx: it came along as a late addition to Glulx's specification. The deal is that we have to explicitly tell the Glk interface layer to perform certain operations in a Unicode way; if we simply perform `print (char) ch;` then the character `ch` will be printed in ZSCII rather than Unicode.

```
[ INDEXED_TEXT_TY_Say indt  ch i dsize;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) return;
    dsize = BlkValueExtent(indt);
    for (i=0:i<dsize:i++) {
        ch = BlkValueRead(indt, i);
        if (ch == 0) break;
        #ifdef TARGET_ZCODE;
        print (char) ch;
        #ifnot; ! TARGET_ZCODE
        glk_put_char_uni(ch);
        #endif;
    }
];
```

§**8. Serialisation.** Here we print a serialised form of an indexed text which can later be used to reconstruct the original text. The printing is apparently to the screen, but in fact always takes place when the output stream is a file.

The format chosen is a letter "S" for string, then a comma-separated list of decimal character codes, ending with the null terminator, and followed by a semicolon: thus `S65,66,67,0;` is the serialised form of the text "ABC".

```
[ INDEXED_TEXT_TY_WriteFile txb len pos ch;
    len = BlkValueExtent(txb);
    print "S";
    for (pos=0: pos<=len: pos++) {
        if (pos == len) ch = 0; else ch = BlkValueRead(txb, pos);
        if (ch == 0) {
            print "0;"; break;
        } else {
            print ch, ",";
        }
    }
];
```

§**9. Unserialisation.** If that's the word: the reverse process, in which we read a stream of characters from a file and reconstruct the indexed text which gave rise to them.

```
[ INDEXED_TEXT_TY_ReadFile indt auxf ch i v dg pos tsize;
    tsize = BlkValueExtent(indt);
    while (ch ~= 32 or 9 or 10 or 13 or 0 or -1) {
        ch = FileIO_GetC(auxf);
        if (ch == ',' or ';') {
            if (pos+1 >= tsize) {
                if (BlkValueSetExtent(indt, 2*pos, 20) == false) break;
                tsize = BlkValueExtent(indt);
            }
            BlkValueWrite(indt, pos++, v);
            v = 0;
            if (ch == ';') break;
        } else {
            dg = ch - '0';
            v = v*10 + dg;
        }
    }
    BlkValueWrite(indt, pos, 0);
    return indt;
];
```

§**10. Recognition-only-GPR.** An I6 general parsing routine to look at words from the position marker `wn` in the player's command to see if they match the contents of the indexed text `indt`, returning either `GPR_PREPOSITION` or `GPR_FAIL` according to whether a match could be made. This is used when the an object's name is set to include one of its properties, and the property in question is an indexed text: "A flowerpot is a kind of thing. A flowerpot has an indexed text called pattern. Understand the pattern property as describing a flowerpot." When the player types EXAMINE STRIPED FLOWERPOT, and there is a flowerpot in scope, the following routine is called to test whether its pattern property – an indexed text – matches any words at the position STRIPED FLOWERPOT. Assuming a pot does indeed have the pattern "striped", the routine advances `wn` by 1 and returns `GPR_PREPOSITION` to indicate a match.

This kind of GPR is called a "recognition-only-GPR", because it only recognises an existing value: it doesn't parse a new one.

```
[ INDEXED_TEXT_TY_ROGPR indt
    pos len wa wl wpos bdm ch own;
    if (indt == 0) return GPR_FAIL;
    bdm = true; own = wn;
    len = BlkValueExtent(indt);
    for (pos=0: pos<=len: pos++) {
        if (pos == len) ch = 0; else ch = BlkValueRead(indt, pos);
        if (ch == 32 or 9 or 10 or 0) {
            if (bdm) continue;
            bdm = true;
            if (wpos ~= wl) return GPR_FAIL;
            if (ch == 0) break;
        } else {
            if (bdm) {
                bdm = false;
                if (NextWordStopped() == -1) return GPR_FAIL;
                wa = WordAddress(wn-1);
                wl = WordLength(wn-1);
                wpos = 0;
            }
            if (wa->wpos ~= ch or IT_RevCase(ch)) return GPR_FAIL;
            wpos++;
        }
    }
    if (wn == own) return GPR_FAIL; ! Progress must be made to avoid looping
    return GPR_PREPOSITION;
];
```

§11. Blobs. That completes the compulsory services required for this KOV to function: from here on, the remaining routines provide definitions of text-related phrases in the Standard Rules.

What are the basic operations of text-handling? Clearly we want to be able to search, and replace, but that is left for the segment "RegExp.i6t" to handle. More basically we would like to be able to read and write characters from the text. But texts in I7 tend to be of natural language, rather than containing arbitrary material – that's indeed why we call them texts rather than strings. This means they are likely to be punctuated sequences of words, divided up perhaps into sentences and even paragraphs.

So we provide facilities which regard a text as being an array of "blobs", where a "blob" is a unit of text. The user can choose whether to see it as an array of characters, or words (of three different sorts: see the Inform documentation for details), or paragraphs, or lines.

```
Constant CHR_BLOB = 1; ! Construe as an array of characters
Constant WORD_BLOB = 2; ! Of words
Constant PWORD_BLOB = 3; ! Of punctuated words
Constant UWORD_BLOB = 4; ! Of unpunctuated words
Constant PARA_BLOB = 5; ! Of paragraphs
Constant LINE_BLOB = 6; ! Of lines
Constant REGEXP_BLOB = 7; ! Not a blob type as such, but needed as a distinct value
```

§12. Blob Access. The following routine runs a small finite-state-machine to count the number of blobs in an indexed text, using any of the above blob types (except `REGEXP_BLOB`, which is used for other purposes). If the optional arguments `cindt` and `wanted` are supplied, it also copies the text of blob number `wanted` (counting upwards from 1 at the start of the text) into the indexed text `cindt`. If the further optional argument `rindt` is supplied, then `cindt` is instead written with the original text `indt` as it would read if the blob in question were replaced with the indexed text in `rindt`.

```
Constant WS_BRM = 1;
Constant SKIPPED_BRM = 2;
Constant ACCEPTED_BRM = 3;
Constant ACCEPTEDP_BRM = 4;
Constant ACCEPTEDN_BRM = 5;
Constant ACCEPTEDPN_BRM = 6;

                    BlkValueWrite(cindt, cl++, ch);
                }
            }
        }
        if (cindt) BlkValueWrite(cindt, cl++, 0);
        return blobcount;
];
```

§**13. Get Blob.** The front end which uses the above routine to read a blob. (Note that, for efficiency's sake, we read characters more directly.)

```
[ IT_GetBlob cindt indt wanted blobtype;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) return;
    if (blobtype == CHR_BLOB) return IT_GetCharacter(cindt, indt, wanted);
    IT_BlobAccess(indt, blobtype, cindt, wanted);
    return cindt;
];
```

§**14. Replace Blob.** The front end which uses the above routine to replace a blob. (Once again, characters are handled directly to avoid incurring all that overhead.)

```
[ IT_ReplaceBlob blobtype indt wanted rindt cindt ilen rlen i;
    if (blobtype == CHR_BLOB) {
        ilen = IT_CharacterLength(indt);
        rlen = IT_CharacterLength(rindt);
        wanted--;
        if ((wanted >= 0) && (wanted<ilen)) {
            if (rlen == 1) {
                BlkValueWrite(indt, wanted, BlkValueRead(rindt, 0));
            } else {
                cindt = BlkValueCreate(INDEXED_TEXT_TY);
                if (BlkValueSetExtent(cindt, ilen+rlen+1, 5)) {
                    for (i=0:i<wanted:i++)
                        BlkValueWrite(cindt, i, BlkValueRead(indt, i));
                    for (i=0:i<rlen:i++)
                        BlkValueWrite(cindt, wanted+i, BlkValueRead(rindt, i));
                    for (i=wanted+1:i<ilen:i++)
                        BlkValueWrite(cindt, rlen+i-1, BlkValueRead(indt, i));
                    BlkValueWrite(cindt, rlen+ilen, 0);
                    BlkValueCopy(indt, cindt);
                }
                BlkFree(cindt);
            }
        }
    } else {
        cindt = BlkValueCreate(INDEXED_TEXT_TY);
        IT_BlobAccess(indt, blobtype, cindt, wanted, rindt);
        BlkValueCopy(indt, cindt);
        BlkFree(cindt);
    }
];
```

§**15. Replace Text.** This is the general routine which searches for any instance of `findt`, as a blob, in `indt`, and replaces it with the text `rindt`. It works on any of the above blob-types, but two cases are special: first, if the blob-type is `CHR_BLOB`, then it can do more than search and replace for any instance of a single character: it can search and replace any instance of a substring, so that `findt` is not required to be only a single character. Second, if the blob-type is the special value `REGEXP_BLOB` then `findt` is interpreted as a regular expression rather than something literal to find: see "RegExp.i6t" for what happens next.

```
[ IT_ReplaceText blobtype indt findt rindt
    cindt csize ilen flen i cl mpos ch chm whitespace punctuation;
    if (blobtype == REGEXP_BLOB or CHR_BLOB)
        return IT_Replace_RE(blobtype, indt, findt, rindt);
    ilen = IT_CharacterLength(indt);
    flen = IT_CharacterLength(findt);
    cindt = BlkValueCreate(INDEXED_TEXT_TY);
    csize = BlkValueExtent(cindt);
    mpos = 0;
    whitespace = true; punctuation = false;
    for (i=0:i<=ilen:i++) {
        ch = BlkValueRead(indt, i);
        .MoreMatching;
        chm = BlkValueRead(findt, mpos++);
        if (mpos == 1) {
            switch (blobtype) {
                WORD_BLOB:
                    if ((whitespace == false) && (punctuation == false)) chm = -1;
            }
        }
        whitespace = false;
        if (ch == 10 or 13 or 32 or 9) whitespace = true;
        punctuation = false;
        if (ch == '.' or ',' or '!' or '?'
            or '-' or '/' or '"' or ':' or ';'
            or '(' or ')' or '[' or ']' or '{' or '}') {
            if (blobtype == WORD_BLOB) chm = -1;
            punctuation = true;
        }
        if (ch == chm) {
            if (mpos == flen) {
                if (i == ilen) chm = 0;
                else chm = BlkValueRead(indt, i+1);
                if ((blobtype == CHR_BLOB) ||
                    (chm == 0 or 10 or 13 or 32 or 9) ||
                    (chm == '.' or ',' or '!' or '?'
                        or '-' or '/' or '"' or ':' or ';'
                        or '(' or ')' or '[' or ']' or '{' or '}')) {
                    mpos = 0;
                    cl = cl - (flen-1);
                    BlkValueWrite(cindt, cl, 0);
                    IT_Concatenate(cindt, rindt, CHR_BLOB);
                    csize = BlkValueExtent(cindt);
                    cl = IT_CharacterLength(cindt);
                    continue;
                }
```

```
            }
        } else {
            mpos = 0;
        }
        if (cl+1 >= csize) {
            if (BlkValueSetExtent(cindt, 2*cl, 9) == false) break;
            csize = BlkValueExtent(cindt);
        }
        BlkValueWrite(cindt, cl++, ch);
    }
    BlkValueCopy(indt, cindt);
    BlkFree(cindt);
];
```

§**16. Character Length.** When accessing at the character-by-character level, things are much easier and we needn't go through any finite state machine palaver.

```
[ IT_CharacterLength indt ch i dsize;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) return 0;
    dsize = BlkValueExtent(indt);
    for (i=0:i<dsize:i++) {
        ch = BlkValueRead(indt, i);
        if (ch == 0) return i;
    }
    return dsize;
];
[ INDEXED_TEXT_TY_Empty indt;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) rfalse;
    if (IT_CharacterLength(indt) == 0) rtrue;
    rfalse;
];
```

§**17. Get Character.** Characters in a text are numbered upwards from 1 by the users of this routine: which is why we subtract 1 when reading the array in the block-value, which counts from 0.

```
[ IT_GetCharacter cindt indt i ch;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) return;
    if ((i<=0) || (i>IT_CharacterLength(indt))) ch = 0;
    else ch = BlkValueRead(indt, i-1);
    BlkValueWrite(cindt, 0, ch);
    BlkValueWrite(cindt, 1, 0);
    return cindt;
];
```

§**18. Casing.** In many programming languages, characters are a distinct data type from strings, but not in I7. To I7, a character is simply an indexed text which happens to have length 1 – this has its inefficiencies, but is conceptually easy for the user.

`IT_CharactersOfCase(indt, case)` determines whether all the characters in `indt` are letters of the given casing: 0 for lower case, 1 for upper case. In the case of ZSCII, this is done correctly handling all of the European accented letters; in the case of Unicode, it follows the Unicode standard.

Note that there is no requirement for `indt` to be only a single character long.

```
[ IT_CharactersOfCase indt case i ch len;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) rfalse;
    len = IT_CharacterLength(indt);
    for (i=0:i<len:i++) {
        ch = BlkValueRead(indt, i);
        if ((ch) && (CharIsOfCase(ch, case) == false)) rfalse;
    }
    rtrue;
];
```

§**19. Change Case.** We set `cindt` to the text in `indt`, except that all the letters are converted to the `case` given (0 for lower, 1 for upper). The definition of what is a "letter", what case it has and what the other-case form is are as specified in the ZSCII and Unicode standards.

```
[ IT_CharactersToCase cindt indt case i ch len bnd;
    if ((indt==0) || (BlkType(indt) ~= INDEXED_TEXT_TY)) return;
    len = IT_CharacterLength(indt);
    if (BlkValueSetExtent(cindt, len+1, 11) == false) return cindt;
    bnd = 1;
    for (i=0:i<len:i++) {
        ch = BlkValueRead(indt, i);
        if (case < 2) {
            BlkValueWrite(cindt, i, CharToCase(ch, case));
        } else {
            BlkValueWrite(cindt, i, CharToCase(ch, bnd));
            if (case == 2) {
                bnd = 0;
                if (ch == 0 or 10 or 13 or 32 or 9
                    or '.' or ',' or '!' or '?'
                    or '-' or '/' or '"' or ':' or ';'
                    or '(' or ')' or '[' or ']' or '{' or '}') bnd = 1;
            }
            if (case == 3) {
                if (ch ~= 0 or 10 or 13 or 32 or 9) {
                    if (bnd == 1) bnd = 0;
                    else {
                        if (ch == '.' or '!' or '?') bnd = 1;
                    }
                }
            }
        }
    }
    BlkValueWrite(cindt, len, 0);
    return cindt;
];
```

§**20. Concatenation.** To concatenate two indexed texts is to place one after the other: thus "green" concatenated with "horn" makes "greenhorn". In this routine, `indt_from` would be "horn", and is added at the end of `indt_to`, which is returned in its expanded state.

When the blob type is `REGEXP_BLOB`, the routine is used not for simple concatenation but to handle the concatenations occurring when a regular expression search-and-replace is going on: see "RegExp.i6t".

```
[ IT_Concatenate indt_to indt_from blobtype indt_ref
    pos len ch i tosize x y case;
    if ((indt_to==0) || (BlkType(indt_to) ~= INDEXED_TEXT_TY)) rfalse;
    if ((indt_from==0) || (BlkType(indt_from) ~= INDEXED_TEXT_TY)) return indt_to;
    switch(blobtype) {
        CHR_BLOB, 0:
            pos = IT_CharacterLength(indt_to);
            len = IT_CharacterLength(indt_from);
            if (BlkValueSetExtent(indt_to, pos+len+1, 10) == false) return indt_to;
            for (i=0:i<len:i++) {
                ch = BlkValueRead(indt_from, i);
                BlkValueWrite(indt_to, i+pos, ch);
            }
            BlkValueWrite(indt_to, len+pos, 0);
            return indt_to;
        REGEXP_BLOB:
            return IT_RE_Concatenate(indt_to, indt_from, blobtype, indt_ref);
        default:
            print "*** IT_Concatenate used on impossible blob type ***^";
            rfalse;
    }
];
```

§**21. Setting the Player's Command.** In effect, the text typed most recently by the player is a sort of indexed text already, though it isn't in indexed text format, and doesn't live on the heap. (We can't simply make it an indexed text, as tidy as that would seem, because then no I7 work could ever compile without a heap to use, and that would severely affect many works which have to fit in the Z-machine and can't afford the storage for a heap.)

```
[ SetPlayersCommand indt_from i len at;
    len = IT_CharacterLength(indt_from);
    if (len > 118) len = 118;
    #ifdef TARGET_ZCODE;
    buffer->1 = len; at = 2;
    #ifnot;
    buffer-->0 = len; at = 4;
    #endif;
    for (i=0:i<len:i++) buffer->(i+at) = CharToCase(BlkValueRead(indt_from, i), 0);
    for (:at+i<120:i++) buffer->(at+i) = ' ';
    VM_Tokenise(buffer, parse);
    players_command = 100 + WordCount(); ! The snippet variable ''player's command''
];
```

§**22. Stubs.** And the usual meaningless versions to ensure that function-names exist if there is no heap, and there are no indexed texts anyway.

```
#IFNOT; ! IFDEF MEMORY_HEAP_SIZE
[ INDEXED_TEXT_TY_Support t a b c; rfalse; ];
[ INDEXED_TEXT_TY_Say indt; ];
[ SetPlayersCommand indt_from; ];
[ INDEXED_TEXT_TY_Create; ];
[ INDEXED_TEXT_TY_Cast a b c; ];
[ INDEXED_TEXT_TY_Empty t; rfalse; ];
#ENDIF; ! IFDEF MEMORY_HEAP_SIZE
```

RegExp Template B/regxt

Purpose

Code to match and replace on regular expressions against indexed text strings.

---

§**1. Head.** As ever: if there is no heap, there are no indexed texts, and if there are no indexed texts then there is no point in compiling any of this code.

```
#IFDEF MEMORY_HEAP_SIZE; ! Will exist if any use is made of indexed texts
Global IT_RE_Trace = false; ! Change to true for (a lot of) debugging data in use
[ IT_RE_SetTrace F; IT_RE_Trace = F; ];
```

§**2. Algorithm.** Once Inform 7 supported indexed text, regular-expression matching became an obvious goal: regexp-based features offer more or less the gold standard in text search and replace facilities, and I7 is so concerned with text that we shouldn't make do with less. But the best and most portable implementation of regular expression matching, PCRE by Philip Hazel, is about a hundred times larger than the code in this section, and also had unacceptable memory needs: there was no practicable way to make it small enough to do useful work on the Z-machine. Nor could an I6 regexp-matcher compile just-in-time code, or translate the expression into a suitable deterministic finite state machine. One day, though, I read one of the papers which Brian Kernighan writes every few years to the effect that regular-expression matching is much easier than you think. Kernighan is right: writing a regexp matcher is indeed easier than you think (one day's worth of cheerful hacking), but debugging one until it passes the trickiest hundred of Perl's 645 test cases is another matter (and it took a whole week more). Still, the result seems to be robust. The main compromise made is that backtracking is not always comprehensive with regexps like `^(a\1?){4}$`, because we do not allocate individual storage to backtrack individually through all possibilities of each of the four uses of the bracketed subexpression – which means we miss some cases, since the subexpression contains a reference to itself, so that its content can vary in the four uses. PCRE's approach here is to expand the expression as if it were a sequence of four bracketed expressions, thus removing the awkward quantifier `{4}`, but that costs memory: indeed this is why PCRE cannot solve all of Perl's test cases without its default memory allocation being raised. In other respects, the algorithm below appears to be accurate if not very fast.

§**3. Class Codes.** While in principle we could keep the match expression in textual form, in practice the syntax of regular expressions is complex enough that this would tricky and rather slow: we would be parsing the same notations over and over again. So we begin by compiling it to a simple tree structure. The tree is made up of nodes, and each node has a "class code": these are identified by the `*_RE_CC` constants below. Note that the class codes below are all negative: this is so that they are distinct from all valid ZSCII or Unicode characters. (ZSCII is used only on the Z-machine, which has a 16-bit word but an 8-bit character set, so that all character values are positive; similarly, Unicode is (for our purposes) a 16-bit character set on a 32-bit virtual machine.)

§**4. Packets.** The nodes of the compiled expression tree are stored in "packets", which are segments of a fixed array. A regexp complicated enough that it cannot be stored in `RE_MAX_PACKETS` packets will be rejected with an error: it looks like a rather low limit, but in fact suffices to handle all of Perl's test cases, some of which are works of diabolism.

A packet is then a record containing 14 fields, with offsets defined by the constants defined below. These fields combine the compilation of the corresponding fragment of the regexp with both the tree structure holding these packets together and also the current state of the temporary variables recording how far we have progressed in trying all of the possible ways to match the packet.

```
Constant RE_MAX_PACKETS = 32;
Constant RE_PACKET_SIZE = 14; ! Words of memory used per packet
Constant RE_PACKET_SIZE_IN_BYTES = WORDSIZE*RE_PACKET_SIZE; ! Bytes used per packet
Array RE_PACKET_space --> RE_MAX_PACKETS*RE_PACKET_SIZE;
Constant RE_CCLASS = 0;      ! One of the class codes defined above
Constant RE_PAR1 = 1;        ! Three parameters whose meaning depends on class code
Constant RE_PAR2 = 2;
Constant RE_PAR3 = 3;
Constant RE_NEXT = 4;        ! Younger sibling in the compiled tree
Constant RE_PREVIOUS = 5;    ! Elder sibling
Constant RE_DOWN = 6;        ! Child
Constant RE_UP = 7;          ! Parent
Constant RE_DATA1 = 8;       ! Backtracking data
Constant RE_DATA2 = 9;
Constant RE_CONSTRAINT = 10;
Constant RE_CACHE1 = 11;
Constant RE_CACHE2 = 12;
Constant RE_MODES = 13;
```

§**5. Nodes.** The routine to create a node, something which happens only during the compilation phase, and also the routine which returns the address of a given node. Nodes are numbered from 0 up to $M-1$, where M is the constant `RE_MAX_PACKETS`.

```
[ IT_RE_Node n cc par1 par2 par3  offset;
    if ((n<0) || (n >= RE_MAX_PACKETS)) rfalse;
    offset = RE_PACKET_space + n*RE_PACKET_SIZE_IN_BYTES;
    offset-->RE_CCLASS = cc;
    offset-->RE_PAR1 = par1;
    offset-->RE_PAR2 = par2;
    offset-->RE_PAR3 = par3;
    offset-->RE_NEXT = NULL;
    offset-->RE_PREVIOUS = NULL;
    offset-->RE_DOWN = NULL;
    offset-->RE_UP = NULL;
    offset-->RE_DATA1 = -1; ! Match start
    offset-->RE_DATA2 = -1; ! Match end
    offset-->RE_CONSTRAINT = -1; ! Rewind edge
    return offset;
];
[ IT_RE_NodeAddress n;
    if ((n<0) || (n >= RE_MAX_PACKETS)) return -1;
    return RE_PACKET_space + n*RE_PACKET_SIZE_IN_BYTES;
];
```

§**6. Match Variables.** A bracketed subexpression can be used as a variable: we support `\1`, ..., `\9` to mean "the value of subexpression 1 to 9", and `\0` to mean "the whole text matched", as if the entire regexp were bracketed. (PCRE and Perl also allow `\10`, `\11`, ..., but we don't, because it complicates parsing and memory is too short.)

`RE_Subexpressions-->10` stores the number of subexpressions in use, not counting `\0`. During the compiling stage, `RE_Subexpressions-->N` is set to point to the node representating `\N`, where `N` varies from 1 to 9. When matching is complete, and assuming we care about the contents of these variables – which we might not, and if not we certainly don't want to waste time and memory – we call `IT_RE_CreateMatchVars` to allocate indexed text variables and fill them in as appropriate, memory permitting.

`IT_RE_EmptyMatchVars` empties any such variables which may survive from a previous match, setting them to the empty text.

```
Array RE_Subexpressions --> 11; ! Address of node for this subexpression
Array Allocated_Match_Vars --> 10; ! Indexed text to hold values of the variables

[ IT_RE_DebugMatchVars indt
    offset n i;
    print RE_Subexpressions-->10, " collecting subexps^";
    for (n=0:(n<RE_Subexpressions-->10) && (n<10): n++) {
        offset = RE_Subexpressions-->n;
        print "Subexp ", offset-->RE_PAR1,
            " = [", offset-->RE_DATA1, ",", offset-->RE_DATA2, "] = ";
        for (i=offset-->RE_DATA1:i<offset-->RE_DATA2:i++)
            print (char) BlkValueRead(indt, i);
        print "^";
    }
];

[ IT_RE_CreateMatchVars indt
    offset n i ch cindt cl csize;
    for (n=0:(n<RE_Subexpressions-->10) && (n<10): n++) {
        offset = RE_Subexpressions-->n;
        if (Allocated_Match_Vars-->n == 0)
            Allocated_Match_Vars-->n = INDEXED_TEXT_TY_Create(); ! Permanently
        cindt = Allocated_Match_Vars-->n;
        csize = BlkValueExtent(cindt);
        cl = 0;
        for (i=offset-->RE_DATA1:i<offset-->RE_DATA2:i++) {
            ch = BlkValueRead(indt, i);
            if (cl+1 >= csize) {
                if (BlkValueSetExtent(cindt, 2*cl, 6) == false) break;
                csize = BlkValueExtent(cindt);
            }
            BlkValueWrite(cindt, cl++, ch);
        }
        BlkValueWrite(cindt, cl, 0);
    }
];

[ IT_RE_EmptyMatchVars indt
    n;
    for (n=0:(n<RE_Subexpressions-->10) && (n<10): n++)
        if (Allocated_Match_Vars-->n ~= 0)
            BlkValueWrite(Allocated_Match_Vars-->n, 0, 0);
];
```

```
[ IT_RE_GetMatchVar indt vn
    offset;
    if ((vn<0) || (vn>=10) || (vn >= RE_Subexpressions-->10)) jump Nope;
    offset = RE_Subexpressions-->vn;
    if (offset == 0) jump Nope;
    if (offset-->RE_DATA1 < 0) jump Nope;
    if (Allocated_Match_Vars-->vn == 0) {
        print "*** ", vn, " unallocated! ***^";
        jump Nope;
    }
    BlkValueCopy(indt, Allocated_Match_Vars-->vn);
    return indt;
    .Nope;
    BlkValueWrite(indt, 0, 0);
    return indt;
];
```

§**7. Markers.** At each node, the `-->RE_DATA1` and `-->RE_DATA2` fields represent the character positions of the start and end of the text matched by the node and its subtree (if any). These are called markers.

Thus `IT_MV_End(N, 0)` returns the start of `\N` and `IT_MV_End(N, 1)` the end of `\N`, according to the current match of subexpression `N`.

```
[ IT_MV_End n end
    offset;
    offset = RE_Subexpressions-->n;
    if (end==0) return offset-->RE_DATA1;
    return offset-->RE_DATA2;
];
[ IT_RE_Clear_Markers token;
    for (: token ~= NULL: token = token-->RE_NEXT) {
        if (token-->RE_DOWN ~= NULL) IT_RE_Clear_Markers(token-->RE_DOWN);
        token-->RE_DATA1 = -1;
        token-->RE_DATA2 = -1;
        token-->RE_CONSTRAINT = -1;
    }
];
```

§**8. Debugging.** Code in this paragraph simply prints a convenient screen representation of the compiled regexp, together with the current values of its markers. It is invaluable for debugging purposes and, touch wood, may not be needed again, but it is relatively compact and we keep it just in case.

```
[ IT_RE_DebugTree findt detail;

§**9. Compiling Tree For Substring Search.** When we search for a literal substring, say looking for "per" in "Supernumerary", we will in fact use the same apparatus as when searching for a regular expression: we compile a very simple node tree in which `\0` as the root contains just one child node, a `LITERAL_RE_CC` matching exactly the text "per". We return 2 since that's the number of nodes in the tree.

```
[ IT_CHR_CompileTree findt exactly
    root literal fto no_packets token attach_to;
    fto = IT_CharacterLength(findt);
    root = IT_RE_Node(0, SUBEXP_RE_CC, 0, 0, 0);
    literal = IT_RE_Node(1, LITERAL_RE_CC, 0, fto, 0);
    root-->RE_DOWN = literal;
    literal-->RE_UP = root;
    if (exactly) {
        no_packets = 2;
        if (no_packets+3 > RE_MAX_PACKETS) return "regexp too complex";
        exactly = RE_PACKET_space-->RE_DOWN;
        token = IT_RE_Node(no_packets++, START_RE_CC, 0, 0, 0);
        RE_PACKET_space-->RE_DOWN = token; token-->RE_UP = RE_PACKET_space;
        attach_to = IT_RE_Node(no_packets++, SUBEXP_RE_CC, -1, 3, 0);
        token-->RE_NEXT = attach_to; attach_to-->RE_PREVIOUS = token;
        attach_to-->RE_UP = RE_PACKET_space;
        attach_to-->RE_NEXT = IT_RE_Node(no_packets++, END_RE_CC, 0, 0, 0);
        (attach_to-->RE_NEXT)-->RE_PREVIOUS = attach_to;
        (attach_to-->RE_NEXT)-->RE_UP = RE_PACKET_space;
        attach_to-->RE_DOWN = exactly;
        while (exactly ~= NULL) {
            exactly-->RE_UP = attach_to; exactly = exactly-->RE_NEXT;
        }
    }
    no_packets = IT_RE_ExpandChoices(RE_PACKET_space, no_packets);
];
```

§**10. Compiling Tree For Regexp Search.** But in general we need to compile a regular expression string into a tree of the kind described above, and here is the routine which does that, returning the number of nodes used to build the tree. The syntax it accepts is very fully documented in *Writing with Inform*, so no details are given here.

```
Array Subexp_Posns --> 20;
[ IT_RE_CompileTree findt exactly
    no_packets ffrom fto cc par1 par2 par3
    quantifiable token attach_to no_subs blevel bits;
    fto = IT_CharacterLength(findt);
    if (fto == 0) {
        IT_RE_Node(no_packets++, NEVER_RE_CC, 0, 0, 0); ! Empty regexp never matches
        return 1;
    }
    attach_to = IT_RE_Node(no_packets++, SUBEXP_RE_CC, 0, 0, 0);
    RE_Subexpressions-->0 = attach_to; RE_Subexpressions-->10 = 1; no_subs = 1;
    quantifiable = false; blevel = 0;
    for (ffrom = 0: ffrom < fto: ) {
        cc = BlkValueRead(findt, ffrom++); par1 = 0; par2 = 0; par3 = 0;
```

```
if (cc == '\') {
    if (ffrom == fto) return "Search pattern not terminated";
    cc = BlkValueRead(findt, ffrom++);
    switch (cc) {
        'b': cc = BOUNDARY_RE_CC;
        'B': cc = NONBOUNDARY_RE_CC;
        'd': cc = DIGIT_RE_CC;
        'D': cc = NONDIGIT_RE_CC;
        'l': cc = LCASE_RE_CC;
        'L': cc = NONLCASE_RE_CC;
        'n': cc = NEWLINE_RE_CC;
        'p': cc = PUNCTUATION_RE_CC;
        'P': cc = NONPUNCTUATION_RE_CC;
        's': cc = WHITESPACE_RE_CC;
        'S': cc = NONWHITESPACE_RE_CC;
        't': cc = TAB_RE_CC;
        'u': cc = UCASE_RE_CC;
        'U': cc = NONUCASE_RE_CC;
        'w': cc = WORD_RE_CC;
        'W': cc = NONWORD_RE_CC;
        default:
            if ((cc >= '1') && (cc <= '9')) {
                par1 = cc-'0';
                cc = VARIABLE_RE_CC;
            } else {
                if (((cc >= 'a') && (cc <= 'z')) ||
                    ((cc >= 'A') && (cc <= 'Z'))) return "unknown escape";
                cc = LITERAL_RE_CC;
                par1 = ffrom-1; par2 = ffrom;
            }
    }
    quantifiable = true;

§**11. Parser.** The virtue of all of that tree compilation is that the code which actually does the work – which parses the source text to see if the regular expression matches it – is much shorter and quicker: indeed, it takes up fewer lines than the compiler part, which goes to show that decoding regular expression syntax is a more complex task than acting upon it. This would have surprised the pioneers of regexp, but the syntax has become much more complicated over the decades because of a steady increase in the number of extended notations. The process shows no sign of stopping, with Python and PCRE continuing to push boundaries beyond Perl, which was once thought the superest, duperest regexp syntax there could be. However: to work.

The main matcher simply starts a recursive subroutine to perform the match. However, the subroutine tests for a match at a particular position in the source text; so the main routine tries the subroutine everywhere convenient in the source text, from left to right, until a match is made – unless the regexp is constrained by a `^` glyph to begin matching at the start of the source text, which will cause a `START_RE_CC` node to be the eldest child of the `\0` root.

```

    }
    return rv;
];
```

§**12. Parse At Position.** `IT_RE_ParseAtPosition(findt, indt, ifrom, ito)` attempts to match text beginning at position `ifrom` in the indexed text `indt` and extending for any length up to position `ito`: it returns the number of characters which were matched (which can legitimately be 0), or -1 if no match could be made. `findt` is the original text of the regular expression in its precompiled form, which we need partly to print good debugging information, but mostly in order to match against a `LITERAL_RE_CC` node.

        }
        token = token-->RE_NEXT;
    }
    return ipos - ifrom;
];
```

§**13. Backtracking.** It would be very straightforward to match regular expressions with the above recursive code if, for every node, there were a fixed number of characters (depending on the node) such that there would either be a match eating that many characters, or else no match at all. If that were true, we could simply march through the text matching until we could match no more, and although some nodes might have ambiguous readings, we could always match the first possibility which worked. There would never be any need to retreat.

Well, in fact that happy state does apply to a surprising number of nodes, and some quite complicated regular expressions can be made which use only them: `<abc>{2}\d\d\1`, for instance, matches a sequence of exactly 6 characters or else fails to match altogether, and there is never any need to backtrack. One reason why backtracking is a fairly good algorithm in practice is that these "good" cases occur fairly often, in subexpressions if not in the entire expression, and the simple method above disposes of them efficiently.

But in an expression like `ab+bb`, there is no alternative to backtracking if we are going to try to match the nodes from left to right: we match the "a", then we match as many "b"s as we can – but then we find that we have to match "bb", and this is necessarily impossible because we have just eaten all of the "b"s available. We therefore backtrack one node to the `b+` and try again. We obviously can't literally try again because that would give the same result: instead we impose a constraint. Suppose it previously matched a row of 23 letter "b"s, so that the quantifier `+` resulted in a multiplicity of 23. We then constrain the node and in effect consider it to be `b{1,22}`, that is, to match at least 1 and at most 22 letter "b"s. That still won't work, as it happens, so we backtrack again with a constraint tightened to make it `b{1,21}`, and now the match occurs as we would hope. When the expression becomes more complex, backtracking becomes a longer-distance, recursive procedure – we have to exhaust all possibilities of a more recent node before tracking back to one from longer ago. (This is why the worst test cases are those which entice us into a long, long series of matches only to find that a guess made right back at the start was ill-fated.)

Rather than describing `IT_RE_SeekBacktrack` in detail here, it is probably more useful to suggest that the reader observe it in action by setting `IT_RE_Trace` and trying a few regular expressions.

```
[ IT_RE_SeekBacktrack token findt downwards ito report_only
    untried;
    for (: token ~= NULL: token = token-->RE_NEXT) {
        if ((IT_RE_Trace) && (report_only == false)) {
            print "Scan for rewind: ";
            IT_RE_DebugNode(token, findt, true);
        }
        if ((token-->RE_CCLASS == SUBEXP_RE_CC) &&
            (token-->RE_PAR2 == 1 or 2 or 4)) {
            if (downwards) rfalse;
            continue;
        }
        if (token-->RE_DOWN ~= NULL) {
            if ((IT_RE_Trace) && (report_only == false)) print "Descend^";
            if (IT_RE_SeekBacktrack(token-->RE_DOWN, findt, false, ito, report_only)) rtrue;
```

```
        }
        untried = false;
        switch (token-->RE_CCLASS) {
            DISJUNCTION_RE_CC:
                if ((token-->RE_DATA2 >= 1) &&
                    (token-->RE_DATA2 < token-->RE_PAR1) &&
                    (token-->RE_CONSTRAINT < token-->RE_PAR1)) { ! Matched but earlier than last
                    if (report_only) rtrue;
                    if (token-->RE_CONSTRAINT == -1)
                        token-->RE_CONSTRAINT = 1;
                    else
                        (token-->RE_CONSTRAINT)++;
                    untried = true;
                }
            QUANTIFIER_RE_CC:
                if (token-->RE_CONSTRAINT ~= -2) {
                    if ((IT_RE_Trace) && (report_only == false)) {
                        print "Quant with cons not -2: ";
                        IT_RE_DebugNode(token, findt, true);
                    }
                    if (token-->RE_DATA2 >= 0) {
                        if (report_only) rtrue;
                        token-->RE_CONSTRAINT = token-->RE_DATA2;
                        untried = true;
                    }
                }
        }
        if (untried) {
            if (IT_RE_Trace) {
                print "Grounds for rewind at: ";
                IT_RE_DebugNode(token, findt, true);
            }
            IT_RE_EraseConstraints(token-->RE_NEXT);
            IT_RE_EraseConstraints(token-->RE_DOWN);
            rtrue;
        }
        if (downwards) rfalse;
    }
    rfalse;
];
```

§**14. Fail Subexpressions.** Here, an attempt to make a complicated match against the node in `token` has failed: that means that any subexpressions which were matched in the course of the attempt must also in retrospect be considered unmatched. So we work down through the subtree at `token` and empty any markers for subexpressions, which in effect clears their backslash variables – this is important as, otherwise, the contents left over could cause the alternative reading of the `token` to be misparsed if it refers to the backslash variables in question. (If you think nobody would ever be crazy enough to write a regular expression like that, you haven't see Perl's test suite.)

If the `downwards` flag is clear, it not only invalidates subexpression matches below the node but also to the right of the node – this is useful for a backtrack which runs back quite some distance.

```
[ IT_RE_FailSubexpressions token downwards;
    for (: token ~= NULL: token = token-->RE_NEXT) {
        if (token-->RE_DOWN ~= NULL) IT_RE_FailSubexpressions(token-->RE_DOWN);
        if (token-->RE_CCLASS == SUBEXP_RE_CC) {
            token-->RE_DATA1 = -1;
            token-->RE_DATA2 = -1;
        }
        if (downwards) break;
    }
];
```

§**15. Erasing Constraints.** As explained above, temporary constraints are placed on some nodes when we are backtracking to test possible cases. When we do backtrack, though, it's important to lift any constraints left over from the previous attempt to parse material which is part of or subsequent to the token whose match attempt has been abandoned.

```
[ IT_RE_EraseConstraints token;
    while (token ~= NULL) {
        switch (token-->RE_CCLASS) {
            DISJUNCTION_RE_CC: token-->RE_CONSTRAINT = -1;
            QUANTIFIER_RE_CC: token-->RE_CONSTRAINT = -1;
        }
        if (token-->RE_DOWN) IT_RE_EraseConstraints(token-->RE_DOWN);
        token = token-->RE_NEXT;
    }
];
```

§**16. Matching Literal Text.** Here we attempt to make a match of the substring of the indexed text `mindt` which runs from character `mfrom` to character `mto`, looking for it at the given position `ipos` in the source text `indt`.

```
[ IT_RE_MatchSubstring indt ipos mindt mfrom mto insens
    i ch;
    if (mfrom < 0) return 0;
    if (insens)
        for (i=mfrom:i<mto:i++) {
            ch = BlkValueRead(mindt, i);
            if (BlkValueRead(indt, ipos++) ~= ch or IT_RevCase(ch))
                return -1;
        }
    else
        for (i=mfrom:i<mto:i++)
            if (BlkValueRead(indt, ipos++) ~= BlkValueRead(mindt, i))
                return -1;
    return mto-mfrom;
];
```

§**17. Matching Character Range.** Suppose that a character range is stored in `findt` between the character positions `rf` and `rt`. Then `IT_RE_Range(ch, findt, rf, rt, negate, insens)` tests whether a given character `ch` lies within that character range, negating the outcome if `negate` is set, and performing comparisons case insensitively if `insens` is set.

```
[ IT_RE_Range ch findt rf rt negate insens
    i chm upper crev;
    if (ch == 0) rfalse;
    if (negate == true) {
        if (IT_RE_Range(ch, findt, rf, rt, false, insens)) rfalse;
        rtrue;
    }
    for (i=rf: i<rt: i++) {
        chm = BlkValueRead(findt, i);
        if ((chm == '\') && (i+1<rt)) {
            chm = BlkValueRead(findt, ++i);
            switch (chm) {
                's':
                    if (ch == 10 or 13 or 32 or 9) rtrue;
                'S':
                    if ((ch) && (ch ~= 10 or 13 or 32 or 9)) rtrue;
                'p':
                    if (ch == '.' or ',' or '!' or '?'
                        or '-' or '/' or '"' or ':' or ';'
                        or '(' or ')' or '[' or ']' or '{' or '}') rtrue;
                'P':
                    if ((ch) && (ch ~= '.' or ',' or '!' or '?'
                        or '-' or '/' or '"' or ':' or ';'
                        or '(' or ')' or '[' or ']' or '{' or '})) rtrue;
                'w':
                    if ((ch) && (ch ~= 10 or 13 or 32 or 9
                        or '.' or ',' or '!' or '?'
                        or '-' or '/' or '"' or ':' or ';'
```

```
                    or '(' or ')' or '[' or ']' or '{' or '}')) rtrue;
            'W':
                if (ch == 10 or 13 or 32 or 9
                    or '.' or ',' or '!' or '?'
                    or '-' or '/' or '"' or ':' or ';'
                    or '(' or ')' or '[' or ']' or '{' or '}') rtrue;
            'd':
                if (ch == '0' or '1' or '2' or '3' or '4'
                    or '5' or '6' or '7' or '8' or '9') rtrue;
            'D':
                if ((ch) && (ch ~= '0' or '1' or '2' or '3' or '4'
                    or '5' or '6' or '7' or '8' or '9')) rtrue;
            'l': if (CharIsOfCase(ch, 0)) rtrue;
            'L': if (CharIsOfCase(ch, 0) == false) rtrue;
            'u': if (CharIsOfCase(ch, 1)) rtrue;
            'U': if (CharIsOfCase(ch, 1) == false) rtrue;
            'n': if (ch == 10) rtrue;
            't': if (ch == 9) rtrue;
        }
    }
    if ((i+2<rt) && (BlkValueRead(findt, i+1) == '-')) {
        upper = BlkValueRead(findt, i+2);
        if ((ch >= chm) && (ch <= upper)) rtrue;
        if (insens) {
            crev = IT_RevCase(ch);
            if ((crev >= chm) && (crev <= upper)) rtrue;
        }
        i=i+2;
    } else {
        if (chm == ch) rtrue;
        if ((insens) && (chm == IT_RevCase(ch))) rtrue;
    }
  }
  rfalse;
];
```

§**18. Search And Replace.** And finally, last but not least: the routine which searches an indexed text `indt` trying to match it against `findt`. If `findtype` is set to `REGEXP_BLOB` then `findt` is expected to be a regular expression such as `ab+(c*de)?`, whereas if `findtype` is `CHR_BLOB` then it is expected only to be a simple string of characters taken literally, such as `frog`.

Each match found is replaced with the indexed text in `rindt`, except that if the blob type is `REGEXP_BLOB` then we recognise a few syntaxes as special: for instance, `\2` expands to the value of subexpression 2 as it was matched – see *Writing with Inform* for details.

The optional argument `insens` is a flag which, if set, causes the matching to be done case insensitively; the optional argument `exactly`, if set, causes the matching to work only if the entire `indt` is matched. (This is not especially useful with regular expressions, because the effect can equally be achieved by turning `ab+c`, say, into `^ab+c$`, but it is indeed useful where the blob type is `CHR_BLOB`.)

For an explanation of the use of the word "blob", see "IndexedText.i6t".

```
[ IT_Replace_RE findtype indt findt rindt insens exactly
    cindt csize ilen i cl mpos cpos ch chm;
    ilen = IT_CharacterLength(indt);
```

```
IT_RE_Err = 0;
switch (findtype) {
    REGEXP_BLOB: i = IT_RE_CompileTree(findt, exactly);
    CHR_BLOB: i = IT_CHR_CompileTree(findt, exactly);
    default: "*** bad findtype ***";
}
if ((i<0) || (i>RE_MAX_PACKETS)) {
    IT_RE_Err = i;
    print "*** Regular expression error: ", (string) IT_RE_Err, " ***^";
    RunTimeProblem(RTP_REGEXPSYNTAXERROR);
    return 0;
}
if (IT_RE_Trace) {
    IT_RE_DebugTree(findt);
    print "(compiled to ", i, " packets)^";
}
if (findtype == REGEXP_BLOB) IT_RE_EmptyMatchVars();
mpos = 0; chm = 0; cpos = 0;
while (IT_RE_Parse(findt, indt, mpos, insens) >= 0) {
    chm++;
    if (IT_RE_Trace) {
        print "^*** Match ", chm, " found (", RE_PACKET_space-->RE_DATA1, ",",
            RE_PACKET_space-->RE_DATA2, "): ";
        if (RE_PACKET_space-->RE_DATA1 == RE_PACKET_space-->RE_DATA2) {
            print "<empty>";
        }
        for (i=RE_PACKET_space-->RE_DATA1:i<RE_PACKET_space-->RE_DATA2:i++) {
            print (char) BlkValueRead(indt, i);
        }
        print " ***^";
    }
    if (rindt == 0) break; ! Accept only one match, replace nothing
    if (rindt ~= 0 or 1) {
        if (chm == 1) {
            cindt = BlkValueCreate(INDEXED_TEXT_TY);
            csize = BlkValueExtent(cindt);
        }
        for (i=cpos:i<RE_PACKET_space-->RE_DATA1:i++) {
            ch = BlkValueRead(indt, i);
            if (cl+1 >= csize) {
                if (BlkValueSetExtent(cindt, 2*cl, 7) == false) break;
                csize = BlkValueExtent(cindt);
            }
            BlkValueWrite(cindt, cl++, ch);
        }
        BlkValueWrite(cindt, cl, 0);
        IT_Concatenate(cindt, rindt, findtype, indt);
        csize = BlkValueExtent(cindt);
        cl = IT_CharacterLength(cindt);
    }
    mpos = RE_PACKET_space-->RE_DATA2; cpos = mpos;
```

```
        if (RE_PACKET_space-->RE_DATA1 == RE_PACKET_space-->RE_DATA2)
            mpos++;
        if (IT_RE_Trace) {
            if (chm == 100) { ! Purely to keep the output from being excessive
                print "(Stopping after 100 matches.)^"; break;
            }
        }
    }
    if (chm > 0) {
        if (rindt ~= 0 or 1) {
            for (i=cpos:i<ilen:i++) {
                ch = BlkValueRead(indt, i);
                if (cl+1 >= csize) {
                    if (BlkValueSetExtent(cindt, 2*cl, 8) == false) break;
                    csize = BlkValueExtent(cindt);
                }
                BlkValueWrite(cindt, cl++, ch);
            }
        }
        if (findtype == REGEXP_BLOB) {
            IT_RE_CreateMatchVars(indt);
            if (IT_RE_Trace)
                IT_RE_DebugMatchVars(indt);
        }
        if (rindt ~= 0 or 1) {
            BlkValueWrite(cindt, cl, 0);
            BlkValueCopy(indt, cindt);
            BlkFree(cindt);
        }
    }
    return chm;
];
```

§**19. Concatenation.** See the corresponding routine in "IndexedText.i6t": this is a variation which handles the special syntaxes used in search-and-replace.

```
[ IT_RE_Concatenate indt_to indt_from blobtype indt_ref
    pos len ch i tosize x y case;
    if ((indt_to==0) || (BlkType(indt_to) ~= INDEXED_TEXT_TY)) rfalse;
    if ((indt_from==0) || (BlkType(indt_from) ~= INDEXED_TEXT_TY)) return indt_to;
    pos = IT_CharacterLength(indt_to);
    tosize = BlkValueExtent(indt_to);
    len = IT_CharacterLength(indt_from);
    for (i=0:i<len:i++) {
        ch = BlkValueRead(indt_from, i);
        if ((ch == '\') && (i < len-1)) {
            ch = BlkValueRead(indt_from, ++i);
            if (ch == 'n') ch = 10;
            if (ch == 't') ch = 9;
            case = -1;
            if (ch == 'l') case = 0;
            if (ch == 'u') case = 1;
```

```
            if (case >= 0) ch = BlkValueRead(indt_from, ++i);
            if ((ch >= '0') && (ch <= '9')) {
                ch = ch - '0';
                if (ch < RE_Subexpressions-->10) {
                    x = (RE_Subexpressions-->ch)-->RE_DATA1;
                    y = (RE_Subexpressions-->ch)-->RE_DATA2;
                    if (x >= 0) {
                        for (:x<y:x++) {
                            ch = BlkValueRead(indt_ref, x);
                            if (pos+1 >= tosize) {
                                if (BlkValueSetExtent(indt_to, 2*tosize, 11) == false) break;
                                tosize = BlkValueExtent(indt_to);
                            }
                            if (case >= 0)
                                BlkValueWrite(indt_to, pos++, CharToCase(ch, case));
                            else
                                BlkValueWrite(indt_to, pos++, ch);
                        }
                    }
                }
                continue;
            }
        }
        if (pos+1 >= tosize) {
            if (BlkValueSetExtent(indt_to, 2*tosize, 12) == false) break;
            tosize = BlkValueExtent(indt_to);
        }
        BlkValueWrite(indt_to, pos++, ch);
    }
    BlkValueWrite(indt_to, pos, 0);
    return indt_to;
];
```

§**20. Stubs.** This time, there are no stubs: if there are no indexed texts, none of these routines is ever referred to.

```
#ENDIF; ! IFDEF MEMORY_HEAP_SIZE
```

Char Template B/chart

Purpose

To decide whether letters are upper or lower case, and convert between the two.

---

§**1. Char Is Of Case.** The following decides whether a character `c` belongs to case `case`, where 0 means lower case and 1 means upper. `c` is interpreted according to the character casing chart in "UnicodeData.i6t", which means, it will be ZSCII for the Z-machine and Unicode for Glulx.

```
[ CharIsOfCase c case
    i tab min max len par;
    if (c<'A') rfalse;
    if (case == 0) {
        if ((c >= 'a') && (c <= 'z')) rtrue;
        tab = CharCasingChart0;
    } else {
        if ((c >= 'A') && (c <= 'Z')) rtrue;
        tab = CharCasingChart1;
    }
    if (c<128) rfalse;
    while (tab-->i) {
        min = tab-->i; i++;
        len = tab-->i; i++;
        i++;
        par = 0;
        if (len<0) { par = 1; len = -len; }
        if (c < min) rfalse;
        if (c < min+len) {
            if (par) { if ((c-min) % 2 == 0) rtrue; }
            else { rtrue; }
        }
    }
    rfalse;
];
```

§**2. Char To Case.** And the following converts character `c` to the desired case, or returns it unchanged if it is not a letter with variant casings.

```
[ CharToCase c case
    i tab min max len par del f;
    if (c<'A') return c;
    if (case == 1) {
        if ((c >= 'a') && (c <= 'z')) return c-32;
        tab = CharCasingChart0;
    } else {
        if ((c >= 'A') && (c <= 'Z')) return c+32;
        tab = CharCasingChart1;
    }
    if (c<128) return c;
    while (tab-->i) {
        min = tab-->i; i++;
        len = tab-->i; i++;
        del = tab-->i; i++;
        par = 0;
        if (len<0) { par = 1; len = -len; }
        if (c < min) return c;
        if (c < min+len) {
            f = false;
            if (par) { if ((c-min) % 2 == 0) f = true; }
            else { f = true; }
            if (f) {
                if (del == UNIC_NCT) return c;
                return c+del;
            }
        }
    }
    return c;
];
```

§**3. Reversing Case.** It's convenient to provide this relatively fast routine to reverse the case of a letter since this is an operation used frequently in regular expression matching (see "RegExp.i6t").

```
#IFDEF TARGET_ZCODE;
[ IT_RevCase ch;
    if (ch<'A') return ch;
    if ((ch >= 'a') && (ch <= 'z')) return ch-'a'+'A';
    if ((ch >= 'A') && (ch <= 'Z')) return ch-'A'+'a';
    if (ch<128) return ch;
    if ((ch >= 155) && (ch <= 157)) return ch+3; ! a, o, u umlaut in ZSCII
    if ((ch >= 158) && (ch <= 160)) return ch-3; ! A, O, U umlaut
    if ((ch >= 164) && (ch <= 165)) return ch+3; ! e, i umlaut
    if ((ch >= 167) && (ch <= 168)) return ch-3; ! E, I umlaut
    if ((ch >= 169) && (ch <= 174)) return ch+6; ! a, e, i, o, u, y acute
    if ((ch >= 175) && (ch <= 180)) return ch-6; ! A, E, I, O, U, Y acute
    if ((ch >= 181) && (ch <= 185)) return ch+5; ! a, e, i, o, u grave
    if ((ch >= 186) && (ch <= 190)) return ch-5; ! A, E, I, O, U grave
    if ((ch >= 191) && (ch <= 195)) return ch+5; ! a, e, i, o, u circumflex
    if ((ch >= 196) && (ch <= 200)) return ch-5; ! A, E, I, O, U circumflex
```

```
    if (ch == 201) return 202; ! a circle
    if (ch == 202) return 201; ! A circle
    if (ch == 203) return 204; ! o slash
    if (ch == 204) return 203; ! O slash
    if ((ch >= 205) && (ch <= 207)) return ch+3; ! a, n, o tilde
    if ((ch >= 208) && (ch <= 210)) return ch-3; ! A, N, O tilde
    if (ch == 211) return 212; ! ae ligature
    if (ch == 212) return 211; ! AE ligature
    if (ch == 213) return 214; ! c cedilla
    if (ch == 214) return 213; ! C cedilla
    if (ch == 215 or 216) return ch+2; ! thorn, eth
    if (ch == 217 or 218) return ch-2; ! Thorn, Eth
    if (ch == 220) return 221; ! oe ligature
    if (ch == 221) return 220; ! OE ligature
    return ch;
];
#IFNOT;
[ IT_RevCase ch;
    if (ch<'A') return ch;
    if ((ch >= 'a') && (ch <= 'z')) return ch-'a'+'A';
    if ((ch >= 'A') && (ch <= 'Z')) return ch-'A'+'a';
    if (ch<128) return ch;
    if (CharIsOfCase(ch, 0)) return CharToCase(ch, 1);
    if (CharIsOfCase(ch, 1)) return CharToCase(ch, 0);
    return ch;
];
#ENDIF;
```

§**4. Testing.** Not actually used: simply for testing the tables.

```
[ CharTestCases case i j;
    for (i=32: i<$E0; i++) {
        if ((i>=127) && (i<155)) continue;
        print i, " - ", (char) i, " -";
        if (CharIsOfCase(i, 0)) print "  lower";
        if (CharIsOfCase(i, 1)) print "  upper";
        j = CharToCase(i, 0); if (j ~= i) print "  tolower: ", (char) j;
        j = CharToCase(i, 1); if (j ~= i) print "  toupper: ", (char) j;
        print "^";
    }
];
```

UnicodeData Template B/unict

Purpose

To tabulate casings in the character set.

§**1. Source.** When this section is included, exactly one of the following constants is defined:

(a) `ZSCII_Tables`, meaning that we will use ZSCII as the character set for characters in indexed text strings.
(b) `Small_Unicode_Tables`, meaning that we will use Unicode but store only single-byte characters, so that only the codes 0 to 255 are valid: in effect ISO Latin-1.
(c) `Large_Unicode_Tables`, meaning that we will use Unicode and store two-byte characters, so that all of Unicode in the range 0 to 65535 are valid.

Whichever is defined, we must create two arrays:

(i) `CharCasingChart0`, a table indicating lower-case letters with transitions to convert them to upper case;
(ii) `CharCasingChart1`, vice versa.

Each array is a sequence of three-word records, consisting of the start of a character range, the size of the range (the number of characters in it), and the numerical offset to convert to the opposite case. For instance, the sequence $(97, 26, -32)$ means the 26 lower-case letters "a" to "z", and marks them as convertible to upper case by subtracting 32 from the character code (so "a", 97, becomes "A", 65). If the size of the range is negative, this indicates that only every alternate code is valid. (This makes for efficient storage since there are large parts of the Unicode number-space in which upper and lower case letters alternate.)

An offset of `UNIC_NCT` means no case change is possible; and any character not included in the ranges below is not a letter.

```
Constant UNIC_NCT = 10000; ! Safe as highest case-change delta is 8383
```

§**2. ZSCII Casing Tables.**

```
#IFDEF ZSCII_Tables;
Array CharCasingChart0 -->
    $0061 (  26) (     -32) $009b (   3) (       3) $00a1 (   1) (UNIC_NCT)
    $00a4 (   2) (       3) $00a6 (   1) (UNIC_NCT) $00a9 (   6) (       6)
    $00b5 (   5) (       5) $00bf (   5) (       5) $00c9 (  -3) (       1)
    $00cd (   3) (       3) $00d3 (  -3) (       1) $00d7 (   2) (       2)
    $00dc (   1) (       1) $0000
;
Array CharCasingChart1 -->
    $0041 (  26) (      32) $009e (   3) (      -3) $00a7 (   2) (      -3)

```

StoredAction Template B/stact

Purpose
Code to support the stored action kind of value.

§**1. Head.** As ever: if there is no heap, there are no stored actions.

```
#IFDEF MEMORY_HEAP_SIZE; ! Will exist if any use is made of indexed texts
```

§**2. KOV Support.** See the "BlockValues.i6t" segment for the specification of the following routines.

```
[ STORED_ACTION_TY_Support task arg1 arg2 arg3;
    switch(task) {
        CREATE_KOVS:     return STORED_ACTION_TY_Create();
        CAST_KOVS:       rfalse;
        DESTROY_KOVS:    return STORED_ACTION_TY_Destroy(arg1);
        PRECOPY_KOVS:    rfalse;
        COPY_KOVS:       return STORED_ACTION_TY_Copy(arg1, arg2);
        COMPARE_KOVS:    return STORED_ACTION_TY_Compare(arg1, arg2);
        READ_FILE_KOVS:  rfalse;
        WRITE_FILE_KOVS: rfalse;
    }
];
```

§**3. Creation.** A stored action block has fixed size, so this is a single-block KOV: its data consists of six words, laid out as shown in the following routine. Note that it initialises to the default value for this KOV, an action in which the player waits.

An action which involves a topic – such as the one produced by the command LOOK UP JIM MCDIVITT IN ENCYCLOPAEDIA – cannot be tried without the text of that topic (JIM MCDIVITT) being available. That's no problem if the action is tried in the same turn in which it is generated, because the text will still be in the command buffer. But once we store actions up for future use it becomes an issue. So when we store an action involving a topic, we record the actual text typed at the time when it is stored, and this goes into array entry 5 of the block. Because that in turn is indexed text, and therefore a block value on the heap in its own right, we have to be a little more careful about destroying and copying stored actions than we otherwise would be.

Note that entries 1 and 2 are values whose kind depends on the action in entry 0: but they are never block values, because actions are not allowed to apply to block values. This simplifies matters considerably.

```
[ STORED_ACTION_TY_Create stora;
    stora = BlkAllocate(6*WORDSIZE, STORED_ACTION_TY, BLK_FLAG_WORD);
    BlkValueWrite(stora, 0, ##Wait); ! action
    BlkValueWrite(stora, 1, 0); ! noun
    BlkValueWrite(stora, 2, 0); ! second
    BlkValueWrite(stora, 3, player); ! actor
    BlkValueWrite(stora, 4, false); ! whether a request
    BlkValueWrite(stora, 5, 0); ! indexed text of command if necessary, 0 if not
    return stora;
];
```

§**4. Setting Up.** In practice it's convenient for NI to have a routine which creates a stored action with a given slate of action variables, rather than have to set them all one at a time, so the following is provided as a shorthand form. (For other kinds of value, we might do this by casting, but we can't regard a quintuplet of variables as a single value to cast from, so we do it this way instead.)

```
[ STORED_ACTION_TY_New a n s ac req  stora;
    if (stora == 0) stora = STORED_ACTION_TY_Create();
    BlkValueWrite(stora, 0, a);
    BlkValueWrite(stora, 1, n);
    BlkValueWrite(stora, 2, s);
    BlkValueWrite(stora, 3, ac);
    BlkValueWrite(stora, 4, req);
    BlkValueWrite(stora, 5, 0);
    return stora;
];
```

§**5. Destruction.** Entries 0 to 4 are forgettable non-block values: only the optional indexed text requires destruction.

```
[ STORED_ACTION_TY_Destroy stora toc;
    toc = BlkValueRead(stora, 5);
    if (toc) BlkFree(toc);
];
```

§**6. Copying.** The only entry needing attention is, again, entry 5: if this is non-zero in the source, then we need to create a new indexed text block to hold a duplicate copy of the text.

```
[ STORED_ACTION_TY_Copy storato storafrom tocfrom tocto;
    tocfrom = BlkValueRead(storafrom, 5);
    if (tocfrom == 0) return;
    tocto = INDEXED_TEXT_TY_Support(CREATE_KOVS);
    BlkValueCopy(tocto, tocfrom);
    BlkValueWrite(storato, 5, tocto);
];
```

§**7. Comparison.** There is no very convincing ordering on stored actions, but we need to devise a comparison which will exhaustively determine whether two actions are or are not different.

```
[ STORED_ACTION_TY_Compare storaleft storaright delta itleft itright;
    delta = BlkValueRead(storaleft, 0) - BlkValueRead(storaright, 0);
    if (delta) return delta;
    delta = BlkValueRead(storaleft, 1) - BlkValueRead(storaright, 1);
    if (delta) return delta;
    delta = BlkValueRead(storaleft, 2) - BlkValueRead(storaright, 2);
    if (delta) return delta;
    delta = BlkValueRead(storaleft, 3) - BlkValueRead(storaright, 3);
    if (delta) return delta;
    delta = BlkValueRead(storaleft, 4) - BlkValueRead(storaright, 4);
    if (delta) return delta;
    itleft = BlkValueRead(storaleft, 5);
    itright = BlkValueRead(storaright, 5);
    if ((itleft ~= 0) && (itright ~= 0))
        return INDEXED_TEXT_TY_Support(COMPARE_KOVS, itleft, itright);
    return itleft - itright;
];
[ STORED_ACTION_TY_Distinguish stora1 stora2;
    if (STORED_ACTION_TY_Compare(stora1, stora2) == 0) rfalse;
    rtrue;
];
```

§**8. Printing.** We share some code here with the routines originally written for the ACTIONS testing command. (The `DB` in `DB_Action` stands for "debugging".) When printing a topic, it prints the relevant words from the player's command: so if our stored action is one which contains an entry 5, then we have to temporarily adopt this as the player's command, and restore the old player's command once printing is done. To do this, we need to save the old player's command, and we do that by creating an indexed text for the duration.

```
[ STORED_ACTION_TY_Say stora text_of_command saved_command;
    if ((stora==0) || (BlkType(stora) ~= STORED_ACTION_TY)) return;
    text_of_command = BlkValueRead(stora, 5);
    if (text_of_command) {
        saved_command = INDEXED_TEXT_TY_Support(CREATE_KOVS);
        INDEXED_TEXT_TY_Support(CAST_KOVS, players_command, SNIPPET_TY, saved_command);
        SetPlayersCommand(text_of_command);
    }
    DB_Action(BlkValueRead(stora, 3), BlkValueRead(stora, 4), BlkValueRead(stora, 0),
        BlkValueRead(stora, 1), BlkValueRead(stora, 2), true);
    if (text_of_command) {
        SetPlayersCommand(saved_command);
        BlkFree(saved_command);
    }
];
```

§**9. Involvement.** That completes the compulsory services required for this KOV to function: from here on, the remaining routines provide definitions of stored action-related phrases in the Standard Rules.

An action "involves" an object if it appears as either the actor or the first or second noun.

```
[ STORED_ACTION_TY_Involves stora item at;
    at = FindAction(BlkValueRead(stora, 0));
    if (at) {
        if ((ActionData-->(at+AD_NOUN_KOV) == OBJECT_TY) &&
            (BlkValueRead(stora, 1) == item)) rtrue;
        if ((ActionData-->(at+AD_SECOND_KOV) == OBJECT_TY) &&
            (BlkValueRead(stora, 2) == item)) rtrue;
    }
    if (BlkValueRead(stora, 3) == item) rtrue;
    rfalse;
];
```

§**10. Nouns.** Extracting the noun or second noun from an action is a delicate business because simply returning the values in entries 1 and 2 would not be type-safe; it would fail to be an object if the stored action did not apply to objects. So the following returns `nothing` if requested to produce noun or second noun for such an action.

```
[ STORED_ACTION_TY_Part stora ind at ado;
    if (ind == 1 or 2) {
        if (ind == 1) ado = AD_NOUN_KOV; else ado = AD_SECOND_KOV;
        at = FindAction(BlkValueRead(stora, 0));
        if ((at) && (ActionData-->(at+ado) == OBJECT_TY)) return BlkValueRead(stora, ind);
        return nothing;
    }
    return BlkValueRead(stora, ind);
];
```

§**11. Pattern Matching.** In order to apply an action pattern such as "doing something with the kazoo" to a stored action, it needs to be the current action, because the code which compiles conditions like this looks at the `action`, `noun`, ..., variables. We don't want to do anything as disruptive as temporarily starting the stored action and then halting it again, so instead we simply "adopt" it, saving the slate of action variables and setting them from the stored action: almost immediately after – the moment the condition has been tested – we "unadopt" it again, restoring the stored values. Since the action pattern cannot itself refer to a stored action, the following code won't be nested, and we don't need to worry about stacking up saved copies of the action variables.

`SAT_Tmp-->0` stores the outcome of the condition, and is set in code compiled by NI.

```
Array SAT_Tmp-->6;
[ STORED_ACTION_TY_Adopt stora;
    SAT_Tmp-->1 = action;
    SAT_Tmp-->2 = noun;
    SAT_Tmp-->3 = second;
    SAT_Tmp-->4 = actor;
    SAT_Tmp-->5 = act_requester;
    action = BlkValueRead(stora, 0);
    noun = BlkValueRead(stora, 1);
    second = BlkValueRead(stora, 2);
    actor = BlkValueRead(stora, 3);
```

```
    if (BlkValueRead(stora, 4)) act_requester = player; else act_requester = nothing;
];
[ STORED_ACTION_TY_Unadopt;
    action = SAT_Tmp-->1;
    noun = SAT_Tmp-->2;
    second = SAT_Tmp-->3;
    actor = SAT_Tmp-->4;
    act_requester = SAT_Tmp-->5;
    return SAT_Tmp-->0;
];
```

§**12. Current Action.** Although we never cast other values to stored actions, because none of them really imply an action (not even an action-name, since that gives no help as to what the nouns might be), there is of course one action almost always present within a story file at run-time, even if it is not a single value as such: the action which is currently running. The following routine translates that into a stored action – thus allowing us to store it.

This is the place where we look to see if the action applies to a topic as either its noun or second noun, and if it does, we copy the player's command into an indexed text block-value in entry 5.

```
[ STORED_ACTION_TY_Current stora at text_of_command;
    if ((stora==0) || (BlkType(stora) ~= STORED_ACTION_TY)) return 0;
    BlkValueWrite(stora, 0, action);
    BlkValueWrite(stora, 1, noun);
    BlkValueWrite(stora, 2, second);
    BlkValueWrite(stora, 3, actor);
    if (act_requester) BlkValueWrite(stora, 4, true); else BlkValueWrite(stora, 4, false);
    at = FindAction(-1);
    if ((at) && ((ActionData-->(at+AD_NOUN_KOV) == UNDERSTANDING_TY) ||
             (ActionData-->(at+AD_SECOND_KOV) == UNDERSTANDING_TY))) {
        text_of_command = BlkValueRead(stora, 5);
        if (text_of_command == 0) {
            text_of_command = INDEXED_TEXT_TY_Support(CREATE_KOVS);
            BlkValueWrite(stora, 5, text_of_command);
        }
        INDEXED_TEXT_TY_Support(CAST_KOVS, players_command, SNIPPET_TY, text_of_command);
    } else BlkValueWrite(stora, 5, 0);
    return stora;
];
```

§**13. Trying.** Finally: having stored an action for perhaps many turns, we now let it happen, either silently or not.

```
[ STORED_ACTION_TY_Try stora ks  text_of_command saved_command;
    if ((stora==0) || (BlkType(stora) ~= STORED_ACTION_TY)) return;
    if (ks) { @push keep_silent; keep_silent=1; }
    text_of_command = BlkValueRead(stora, 5);
    if (text_of_command) {
        saved_command = INDEXED_TEXT_TY_Support(CREATE_KOVS);
        INDEXED_TEXT_TY_Support(CAST_KOVS, players_command, SNIPPET_TY, saved_command);
        SetPlayersCommand(text_of_command);
    }
    TryAction(BlkValueRead(stora, 4), BlkValueRead(stora, 3),
        BlkValueRead(stora, 0), BlkValueRead(stora, 1), BlkValueRead(stora, 2));
    if (text_of_command) {
        SetPlayersCommand(saved_command);
        BlkFree(saved_command);
    }
    if (ks) { @pull keep_silent; }
];
```

§**14. Stubs.** And the usual meaningless versions to ensure that function-names exist if there is no heap, and there are no stored actions anyway.

```
#IFNOT; ! IFDEF MEMORY_HEAP_SIZE
[ STORED_ACTION_TY_Say stora; ];
[ STORED_ACTION_TY_New a n s ac req stora; return false; ];
[ STORED_ACTION_TY_Support t a b c; rfalse; ];
#ENDIF; ! IFDEF MEMORY_HEAP_SIZE
```

Lists Template B/listt

Purpose

Code to support the list of... kind of value constructor.

§**1. Head.** As ever: if there is no heap, there are no lists (in this sense).

```
#IFDEF MEMORY_HEAP_SIZE; ! Will exist if any use is made of heap
```

§**2. KOV Support.** See the "BlockValues.i6t" segment for the specification of the following routines.

```
[ LIST_OF_TY_Support task arg1 arg2 arg3;
    switch(task) {
        CREATE_KOVS:     arg3 = LIST_OF_TY_Create(arg2);
                         if (arg1) LIST_OF_TY_CopyRawArray(arg3, arg1, 2);
                         return arg3;
        CAST_KOVS:       rfalse;
        DESTROY_KOVS:    return LIST_OF_TY_Destroy(arg1);
        PRECOPY_KOVS:    return LIST_OF_TY_PreCopy(arg1, arg2);
        COPY_KOVS:       return LIST_OF_TY_Copy(arg1, arg2);
        COMPARE_KOVS:    return LIST_OF_TY_Compare(arg1, arg2);
        READ_FILE_KOVS:  rfalse;
        WRITE_FILE_KOVS: rfalse;
    }
];
```

§**3. Creation.** A list is a multiple-block value with word-sized entries: the first few entries of the block are used for details about the list; the items in the the list then follow. Thus, to convert an item index to an array entry index, add `LIST_ITEM_BASE`.

Lists are by default created empty but in a block-value with enough capacity to hold 25 items, this being what's left in a 32-word block once all overheads are taken care of: 4 words are consumed by the header, then 3 more by the list metadata entries below.

```
Constant LIST_ITEM_KOV_F = 0; ! Entry 0: base KOV stored within
Constant LIST_LENGTH_F = 1; ! Entry 1: length, i.e., number of items
Constant LIST_ITEM_COMPARE_F = 2; ! Entry 2: comparison function for items
Constant LIST_ITEM_BASE = 3; ! List items begin at this entry

[ LIST_OF_TY_Create skov list;
    list = BlkAllocate(28*WORDSIZE, LIST_OF_TY, BLK_FLAG_MULTIPLE + BLK_FLAG_WORD);
    BlkValueWrite(list, LIST_ITEM_KOV_F, skov);
    BlkValueWrite(list, LIST_LENGTH_F, 0);
    BlkValueWrite(list, LIST_ITEM_COMPARE_F, KOVComparisonFunction(skov));
    return list;
];
```

§**4. Setting Up.** NI needs to compile code which will create constant lists such as `{1, 4, 9}` at run-time: the following routine is convenient for that. A "raw array" in this routine's sense is an array `raw` such that `raw-->2` contains the number of items, `raw-->1` the kind of value, and `raw-->3` onwards are the items themselves.

```
[ LIST_OF_TY_CopyRawArray list arr rea len i ex bk v w;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    ex = BlkValueExtent(list);
    len = arr-->2;
    if ((len+LIST_ITEM_BASE > ex) &&
        (BlkValueSetExtent(list, len+LIST_ITEM_BASE) == false)) return 0;
    BlkValueWrite(list, LIST_LENGTH_F, len);
    if (rea == 2) bk = BlkValueRead(list, LIST_ITEM_KOV_F);
    else {
        bk = arr-->1;
        BlkValueWrite(list, LIST_ITEM_KOV_F, bk);
    }
    BlkValueWrite(list, LIST_ITEM_COMPARE_F, KOVComparisonFunction(arr-->1));
    for (i=0:i<len:i++) {
        v = arr-->(i+3);
        if (bk == LIST_OF_TY) {
            w = LIST_OF_TY_Create(v-->1);
            LIST_OF_TY_CopyRawArray(w, v);
            BlkValueWrite(list, i+LIST_ITEM_BASE, w);
        } else {
            if (KOVIsBlockValue(bk)) v = BlkValueCreate(bk, v);
            BlkValueWrite(list, i+LIST_ITEM_BASE, v);
        }
    }
    #ifdef SHOW_ALLOCATIONS;
    print "Copied raw array to list: "; LIST_OF_TY_Say(list, 1); print "^";
    #endif;
    return list;
];
```

§**5. Destruction.** If the list items are themselves block-values, they must all be freed before the list itself can be freed.

```
[ LIST_OF_TY_Destroy list no_items i;
    if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F))) {
        no_items = BlkValueRead(list, LIST_LENGTH_F);
        for (i=0; i<no_items; i++) BlkFree(BlkValueRead(list, i+LIST_ITEM_BASE));
    }
    return list;
];
```

§**6. Copying.** Again, if the list contains block-values then they must be duplicated rather than bitwise copied as pointers.

Note that we use the pre-copy stage to remember the kind of value stored in the list. Type-checking ordinarily means that one list can only be copied into another if they have the same kind of contents: but there is one exception, which is when the list being copied is the empty list.

```
Global precopied_list_kov;

[ LIST_OF_TY_PreCopy lto lfrom list no_items i nv bk;
    precopied_list_kov = BlkValueRead(lto, LIST_ITEM_KOV_F);
];

[ LIST_OF_TY_Copy lto lfrom list no_items i nv bk;
    no_items = BlkValueRead(lfrom, LIST_LENGTH_F);
    bk = BlkValueRead(lfrom, LIST_ITEM_KOV_F);
    BlkValueWrite(lto, LIST_ITEM_KOV_F, precopied_list_kov);
    if ((precopied_list_kov == INDEXED_TEXT_TY) && (bk == TEXT_TY)) {
        for (i=0; i<no_items; i++) {
            nv = BlkValueCreate(INDEXED_TEXT_TY);
            INDEXED_TEXT_TY_Cast(BlkValueRead(lfrom, i+LIST_ITEM_BASE), TEXT_TY, nv);
            BlkValueWrite(lto, i+LIST_ITEM_BASE, nv);
        }
    } else {
        if (KOVIsBlockValue(BlkValueRead(lfrom, LIST_ITEM_KOV_F))) {
            for (i=0; i<no_items; i++) {
                nv = BlkValueCreate(bk);
                BlkValueCopy(nv, BlkValueRead(lfrom, i+LIST_ITEM_BASE));
                BlkValueWrite(lto, i+LIST_ITEM_BASE, nv);
            }
        }
    }
];
```

§**7. Comparison.** Lists of a given kind of value are always grouped together, in this comparison: but the effect of that is unlikely to be noticed since NI's type-checker will probably prevent comparisons of lists of differing items in any case. The next criterion is length: a short list precedes a long one. Beyond that, we use the list's own preferred comparison function to judge the items in turn, stopping as soon as a pair of corresponding items differs: thus we sort lists of equal size in lexicographic order.

Since the comparison function depends only on the KOV, it may seem wasteful of a word of memory to store it in the list, given that we are already storing the KOV in any case. But we do this because comparisons have to be fast: we don't want to incur the overhead of translating KOV to comparison function.

```
[ LIST_OF_TY_Compare listleft listright delta no_items i cf;
    delta = BlkValueRead(listleft, LIST_ITEM_KOV_F) - BlkValueRead(listright, LIST_ITEM_KOV_F);
    if (delta) return delta;
    delta = BlkValueRead(listleft, LIST_LENGTH_F) - BlkValueRead(listright, LIST_LENGTH_F);
    if (delta) return delta;
    no_items = BlkValueRead(listleft, LIST_LENGTH_F);
    cf = BlkValueRead(listleft, LIST_ITEM_COMPARE_F);
    if (cf == 0 or UnsignedCompare) {
        for (i=0; i<no_items; i++) {
            delta = BlkValueRead(listleft, i+LIST_ITEM_BASE) -
                BlkValueRead(listright, i+LIST_ITEM_BASE);
            if (delta) return delta;
```

```
        }
    } else {
        for (i=0; i<no_items; i++) {
            delta = cf(BlkValueRead(listleft, i+LIST_ITEM_BASE),
                BlkValueRead(listright, i+LIST_ITEM_BASE));
            if (delta) return delta;
        }
    }
    return 0;
];
[ LIST_OF_TY_Distinguish txb1 txb2;
    if (LIST_OF_TY_Compare(txb1, txb2) == 0) rfalse;
    rtrue;
];
```

§**8. Printing.** Unusually, this function can print the value in one of several formats: 0 for a comma-separated list; 1 for a braced, set-notation list; 2 for a comma-separated list with definite articles, which only makes sense if the list contains objects; 3 for a comma-separated list with indefinite articles. Note that a list in this sense is *not* printed using the "ListWriter.i6t" code for elaborate lists of objects, and it doesn't use the "listing contents of..." activity in any circumstances.

```
[ LIST_OF_TY_Say list format no_items v i bk;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    bk = BlkValueRead(list, LIST_ITEM_KOV_F);
    ! print "kov=", bk, ":";
    if (format == 1) print "{";
    for (i=0:i<no_items:i++) {
        v = BlkValueRead(list, i+LIST_ITEM_BASE);
        switch (format) {
            2: print (the) v;
            3: print (a) v;
            default:
                if (bk == LIST_OF_TY) LIST_OF_TY_Say(v, 1);
                else if ((bk == TEXT_TY or INDEXED_TEXT_TY) && (format == 1)) {
                    print "~"; PrintKindValuePair(bk, v); print "~";
                }
                else PrintKindValuePair(bk, v);
        }
        if (i<no_items-2) print ", ";
        if (i==no_items-2) {
            if (format == 1) print ", "; else {
                #ifdef SERIAL_COMMA; print ","; #endif;
                print (string) LISTAND2__TX;
            }
        }
    }
    if (format == 1) print "}";
];
```

§**9. List From Description.** That completes the compulsory services required for this KOV to function: from here on, the remaining routines provide definitions of stored action-related phrases in the Standard Rules.

Given a description `D` which applies to some objects and not others – say, "lighted rooms adjacent to the Transport Hub" – we can cast this into a list of all objects satisfying `D` with the following routine. Slightly wastefully of time, we have to iterate through the objects twice in order first to work out the length of list we will need, and then to transcribe them.

```
[ LIST_OF_TY_Desc list desc kov obj no_items ex len i;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    ex = BlkValueExtent(list);
    len = desc(-3);
! for (len=0, obj=desc(-2, nothing, len): obj: len++, obj=desc(-2, obj, len)) ;
! len++;
    if (len+LIST_ITEM_BASE > ex) {
        if (BlkValueSetExtent(list, len+LIST_ITEM_BASE) == false)
            return 0;
    }
    if (kov) BlkValueWrite(list, LIST_ITEM_KOV_F, kov);
    else BlkValueWrite(list, LIST_ITEM_KOV_F, OBJECT_TY);
    BlkValueWrite(list, LIST_LENGTH_F, len);
    obj = 0;
    for (i=0: i<len: i++) {
        obj = desc(-2, obj, i);
        ! print "i = ", i, " and obj = ", obj, "^";
        BlkValueWrite(list, i+LIST_ITEM_BASE, obj);
    }
    return list;
];
```

§**10. Find Item.** We test whether a list `list` includes a value equal to `v` or not. Equality here is in the sense of the list's comparison function: thus for indexed texts or other lists, say, deep comparisons rather than simple pointer comparisons are performed. In other words, one copy of "Alert" is equal to another.

```
[ LIST_OF_TY_FindItem list v i no_items cf;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) rfalse;
    cf = BlkValueRead(list, LIST_ITEM_COMPARE_F);
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if (cf == 0 or UnsignedCompare) {
        for (i=0; i<no_items; i++)
            if (v == BlkValueRead(list, i+LIST_ITEM_BASE)) rtrue;
    } else {
        for (i=0; i<no_items; i++)
            if (cf(v, BlkValueRead(list, i+LIST_ITEM_BASE)) == 0) rtrue;
    }
    rfalse;
];
```

§**11. Insert Item.** The following routine inserts an item into the list. If this would break the size of the current block-value, then we extend by at least enough room to hold at least another 16 entries.

In the call `LIST_OF_TY_InsertItem(list, v, posnflag, posn, nodups)`, only the first two arguments are compulsory.

(a) If `nodups` is set, and an item equal to `v` is already present in the list, we return and do nothing. (`nodups` means "no duplicates".)
(b) Otherwise, if `posnflag` is `false`, we append a new entry `v` at the back of the given `list`.
(c) Otherwise, when `posnflag` is `true`, `posn` indicates the insertion position, from 1 (before the current first item) to $N + 1$ (after the last), where N is the number of items in the list at present.

```
[ LIST_OF_TY_InsertItem list v posnflag posn nodups i no_items ex nv;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    if (nodups && (LIST_OF_TY_FindItem(list, v))) return list;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if ((posnflag) && ((posn<1) || (posn > no_items+1))) {
        print "*** Couldn't add at entry ", posn, " in the list ";
        LIST_OF_TY_Say(list, true);
        print ", which has entries in the range 1 to ", no_items, " ***^";
        RunTimeProblem(RTP_LISTRANGEERROR);
        rfalse;
    }
    ex = BlkValueExtent(list);
    if (no_items+LIST_ITEM_BASE+1 > ex) {
        if (BlkValueSetExtent(list, ex+16) == false) return 0;
    }
    if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F))) {
        nv = BlkValueCreate(BlkValueRead(list, LIST_ITEM_KOV_F));
        BlkValueCopy(nv, v);
        v = nv;
    }
    if (posnflag) {
        posn--;
        for (i=no_items:i>posn:i--) {
            BlkValueWrite(list, i+LIST_ITEM_BASE,
                BlkValueRead(list, i-1+LIST_ITEM_BASE));
        }
        BlkValueWrite(list, posn+LIST_ITEM_BASE, v);
    } else {
        BlkValueWrite(list, no_items+LIST_ITEM_BASE, v);
    }
    BlkValueWrite(list, LIST_LENGTH_F, no_items+1);
    return list;
];
```

§**12. Append List.** Instead of adjoining a single value, we adjoin an entire second list, which must be of a compatible kind of value (something which NI's type-checking machinery polices for us). Except that we have a list `more` rather than a value `v` to insert, the specification is the same as for `LIST_OF_TY_InsertItem`.

```
[ LIST_OF_TY_AppendList list more posnflag posn nodups v i j no_items msize ex nv;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    if ((more==0) || (BlkType(more) ~= LIST_OF_TY)) return list;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if ((posnflag) && ((posn<1) || (posn > no_items+1))) {
        print "*** Couldn't add at entry ", posn, " in the list ";
        LIST_OF_TY_Say(list, true);
        print ", which has entries in the range 1 to ", no_items, " ***^";
        RunTimeProblem(RTP_LISTRANGEERROR);
        rfalse;
    }
    msize = BlkValueRead(more, LIST_LENGTH_F);
    ex = BlkValueExtent(list);
    if (no_items+msize+LIST_ITEM_BASE > ex) {
        if (BlkValueSetExtent(list, no_items+msize+LIST_ITEM_BASE+8) == false)
            return 0;
    }
    if (posnflag) {
        posn--;
        for (i=no_items+msize:i>=posn+msize:i--) {
            BlkValueWrite(list, i+LIST_ITEM_BASE,
                BlkValueRead(list, i-msize+LIST_ITEM_BASE));
        }
        BlkValueWrite(list, posn, v);
        for (j=0: j<msize: j++) {
            v = BlkValueRead(more, j+LIST_ITEM_BASE);
            if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F))) {
                nv = BlkValueCreate(BlkValueRead(list, LIST_ITEM_KOV_F));
                BlkValueCopy(nv, v);
                v = nv;
            }
            BlkValueWrite(list, posn+j+LIST_ITEM_BASE, v);
        }
    } else {
        for (i=0, j=0: i<msize: i++) {
            v = BlkValueRead(more, i+LIST_ITEM_BASE);
            if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F))) {
                nv = BlkValueCreate(BlkValueRead(list, LIST_ITEM_KOV_F));
                BlkValueCopy(nv, v);
                v = nv;
            }
            if ((nodups == 0) || (LIST_OF_TY_FindItem(list, v) == false)) {
                BlkValueWrite(list, no_items+j+LIST_ITEM_BASE, v);
                j++;
            }
        }
    }
    BlkValueWrite(list, LIST_LENGTH_F, no_items+j);
    return list;
```

```
];
```

§**13. Remove Value.** We remove every instance of the value `v` from the given `list`. If the optional flag `forgive` is set, then we make no complaint if no value of `v` was present in the first place: otherwise, we issue a run-time problem.

Note that if the list contains block-values then the value must be properly destroyed with `BlkFree` before being overwritten as the items shuffle down.

```
[ LIST_OF_TY_RemoveValue list v forgive i j no_items odsize f cf delendum;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) rfalse;
    cf = BlkValueRead(list, LIST_ITEM_COMPARE_F);
    no_items = BlkValueRead(list, LIST_LENGTH_F); odsize = no_items;
    for (i=0; i<no_items; i++) {
        delendum = BlkValueRead(list, i+LIST_ITEM_BASE);
        if (cf == 0 or UnsignedCompare)
            f = (v == delendum);
        else
            f = (cf(v, delendum) == 0);
        if (f) {
            if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F)))
                BlkFree(delendum);
            for (j=i+1; j<no_items; j++)
                BlkValueWrite(list, j-1+LIST_ITEM_BASE,
                    BlkValueRead(list, j+LIST_ITEM_BASE));
            no_items--; i--;
            BlkValueWrite(list, LIST_LENGTH_F, no_items);
        }
    }
    if (odsize ~= no_items) rfalse;
    if (forgive) rfalse;
    print "*** Couldn't remove: the value ";
    PrintKindValuePair(BlkValueRead(list, LIST_ITEM_KOV_F), v);
    print " was not present in the list ";
    LIST_OF_TY_Say(list, true);
    print " ***^";
    RunTimeProblem(RTP_LISTRANGEERROR);
];
```

§**14. Remove Item Range.** We excise items `from` to `to` from the given `list`, which numbers its items upwards from 1. If the optional flag `forgive` is set, then we truncate a range overspilling the actual list, and we make no complaint if it turns out that there is then nothing to be done: otherwise, in either event, we issue a run-time problem.

Once again, we destroy any block-values whose pointers will be overwritten as the list shuffles down to fill the void.

```
[ LIST_OF_TY_RemoveItemRange list from to forgive i d no_items;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) rfalse;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if ((from > to) || (from <= 0) || (to > no_items)) {
        if (forgive) {
            if (from <= 0) from = 1;
            if (to >= no_items) to = no_items;
            if (from > to) return list;
        } else {
            print "*** Couldn't remove entries ", from, " to ", to, " from the list ";
            LIST_OF_TY_Say(list, true);
            print ", which has entries in the range 1 to ", no_items, " ***^";
            RunTimeProblem(RTP_LISTRANGEERROR);
            rfalse;
        }
    }
    to--; from--;
    d = to-from+1;
    if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F)))
        for (i=0; i<d; i++)
            BlkFree(BlkValueRead(list, from+i+LIST_ITEM_BASE));
    for (i=from: i<no_items-d: i++)
        BlkValueWrite(list, i+LIST_ITEM_BASE,
            BlkValueRead(list, i+d+LIST_ITEM_BASE));
    BlkValueWrite(list, LIST_LENGTH_F, no_items-d);
    return list;
];
```

§**15. Remove List.** We excise all values from the removal list `rlist`, wherever they occur in `list`. Inevitably, given that we haven't sorted these lists and can spare neither time nor storage to do so, this is an expensive process with a running time proportional to the product of the two list sizes: we accept that as an overhead because in practice the `rlist` is almost always small in real-world use.

If the initial lists were disjoint, so that no removals occur, we always forgive the user: the request was not necessarily a foolish one, it only happened in this situation to be unhelpful.

```
[ LIST_OF_TY_Remove_List list rlist i j k v w no_items odsize rsize cf f;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) rfalse;
    no_items = BlkValueRead(list, LIST_LENGTH_F); odsize = no_items;
    rsize = BlkValueRead(rlist, LIST_LENGTH_F);
    cf = BlkValueRead(list, LIST_ITEM_COMPARE_F);
    for (i=0: i<no_items: i++) {
        v = BlkValueRead(list, i+LIST_ITEM_BASE);
        for (k=0: k<rsize: k++) {
            w = BlkValueRead(rlist, k+LIST_ITEM_BASE);
            if (cf == 0 or UnsignedCompare)
```

```
                f = (v == w);
            else
                f = (cf(v, w) == 0);
            if (f) {
                if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F)))
                    BlkFree(v);
                for (j=i+1: j<no_items: j++)
                    BlkValueWrite(list, j+LIST_ITEM_BASE-1,
                        BlkValueRead(list, j+LIST_ITEM_BASE));
                no_items--; i--;
                BlkValueWrite(list, LIST_LENGTH_F, no_items);
                break;
            }
        }
    }
    rfalse;
];
```

§16. Get Length.

```
[ LIST_OF_TY_GetLength list;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return 0;
    return BlkValueRead(list, LIST_LENGTH_F);
];
[ LIST_OF_TY_Empty list;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) rfalse;
    if (BlkValueRead(list, LIST_LENGTH_F) == 0) rtrue;
    rfalse;
];
```

§17. Set Length. This is rather harder: it might lengthen the list, in which case we have to pad out with the default value for the kind of value stored – padding a list of numbers with 0s, a list of texts with copies of the empty text, and so on – creating such block-values as might be needed; or else it might shorten the list, in which case we must cut items, destroying them properly if they were block-values.

`LIST_OF_TY_SetLength(list, newsize, this_way_only, truncation_end)` alters the length of the given `list` to `newsize`. If `this_way_only` is 1, the list is only allowed to grow, and nothing happens if we have asked to shrink it; if it is -1, the list is only allowed to shrink; if it is 0, the list is allowed either to grow or shrink. In the event that the list does have to shrink, entries must be removed, and we remove from the end if `truncation_end` is 1, or from the start if it is -1.

```
[ LIST_OF_TY_SetLength list newsize this_way_only truncation_end no_items ex i dv;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return 0;
    if (newsize < 0) "*** Cannot resize a list to negative length ***";
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if (no_items < newsize) {
        if (this_way_only == -1) return list;
        ex = BlkValueExtent(list);
        if (newsize+LIST_ITEM_BASE > ex) {
            if (BlkValueSetExtent(list, newsize+LIST_ITEM_BASE) == false)
                return 0;
        }
        dv = DefaultValueOfKOV(BlkValueRead(list, LIST_ITEM_KOV_F));
```

```
        for (i=no_items: i<newsize: i++)
            BlkValueWrite(list, LIST_ITEM_BASE+i, dv);
        BlkValueWrite(list, LIST_LENGTH_F, newsize);
    }
    if (no_items > newsize) {
        if (this_way_only == 1) return list;
        if (truncation_end == -1) {
            if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F)))
                for (i=0: i<no_items-newsize: i++)
                    BlkFree(BlkValueRead(list, LIST_ITEM_BASE+i));
            for (i=0: i<newsize: i++)
                BlkValueWrite(list, LIST_ITEM_BASE+i,
                    BlkValueRead(list, LIST_ITEM_BASE+no_items-newsize+i));
        } else {
            if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F)))
                for (i=newsize: i<no_items: i++)
                    BlkFree(BlkValueRead(list, LIST_ITEM_BASE+i));
        }
        BlkValueWrite(list, LIST_LENGTH_F, newsize);
    }
    return list;
];
```

§18. Get Item.

```
[ LIST_OF_TY_GetItem list i forgive no_items;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if ((i<=0) || (i>no_items)) {
        if (forgive) return false;
        print "*** Couldn't read from list entry ", i, ": the list ";
        LIST_OF_TY_Say(list, true);
        switch (no_items) {
            0: print " is empty ***^";
            1: print " has only one entry, numbered 1 ***^";
            default: print " has entries numbered from 1 to ", no_items, " ***^";
        }
        RunTimeProblem(RTP_LISTRANGEERROR);
        if (no_items >= 1) i = 1;
        else return false;
    }
    return BlkValueRead(list, LIST_ITEM_BASE+i-1);
];
```

§**19. Write Item.** The slightly odd name for this function comes about because our usual way to convert an rvalue such as `LIST_OF_TY_GetItem(L, 4)` is to prefix `Write`, so that it becomes `WriteLIST_OF_TY_GetItem(L, 4)`.

```
[ WriteLIST_OF_TY_GetItem list i val no_items;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if ((i<=0) || (i>no_items)) {
        print "*** Couldn't write to list entry ", i, ": the list ";
        LIST_OF_TY_Say(list, true);
        switch (no_items) {
            0: print " is empty ***^";
            1: print " has only one entry, numbered 1 ***^";
            default: print " has entries numbered from 1 to ", no_items, " ***^";
        }
        return RunTimeProblem(RTP_LISTRANGEERROR);
    }
    BlkValueWrite(list, LIST_ITEM_BASE+i-1, val);
];
```

§**20. Put Item.** Higher-level code should not use `Write_LIST_OF_TY_GetItem`, because it does not properly keep track of block-value copying: the following should be used instead.

```
[ LIST_OF_TY_PutItem list i v  no_items nv;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return false;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if (KOVIsBlockValue(BlkValueRead(list, LIST_ITEM_KOV_F))) {
        nv = BlkValueCreate(BlkValueRead(list, LIST_ITEM_KOV_F));
        BlkValueCopy(nv, v);
        v = nv;
    }
    if ((i<=0) || (i>no_items)) return false;
    BlkValueWrite(list, LIST_ITEM_BASE+i-1, v);
];
```

§**21. Multiple Object List.** The parser uses one data structure which is really a list: but which can't be represented as such because the heap might not exist. This is the multiple object list, which is used to handle commands like TAKE ALL by firing off a sequence of actions with one of the objects taken from entries in turn of the list. The following converts it to a list structure.

```
[ LIST_OF_TY_Mol list len i;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return 0;
    len = multiple_object-->0;
    LIST_OF_TY_SetLength(list, len);
    for (i=1: i<=len: i++)
        LIST_OF_TY_PutItem(list, i, multiple_object-->i);
    return list;
];
[ LIST_OF_TY_Set_Mol list len i;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return 0;
    len = BlkValueRead(list, LIST_LENGTH_F);
    if (len > 63) len = 63;
```

```
    multiple_object-->0 = len;
    for (i=1: i<=len: i++)
        multiple_object-->i = BlkValueRead(list, LIST_ITEM_BASE+i-1);
];
```

§**22. Reversing.** Reversing a list is, happily, a very efficient operation when the list contains block-values: because the pointers are rearranged but none is duplicated or destroyed, we can for once ignore the fact that they are pointers to block-values and simply move them around like any other data.

```
[ LIST_OF_TY_Reverse list no_items i v;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return 0;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if (no_items < 2) return list;
    for (i=0;i*2<no_items;i++) {
        v = BlkValueRead(list, LIST_ITEM_BASE+i);
        BlkValueWrite(list, LIST_ITEM_BASE+i,
            BlkValueRead(list, LIST_ITEM_BASE+no_items-1-i));
        BlkValueWrite(list, LIST_ITEM_BASE+no_items-1-i, v);
    }
    return list;
];
```

§**23. Rotation.** The same is true of rotation. Here, "forwards" rotation means towards the end of the list, "backwards" means towards the start.

```
[ LIST_OF_TY_Rotate list backwards  no_items i v;
    if ((list==0) || (BlkType(list) ~= LIST_OF_TY)) return 0;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if (no_items < 2) return list;
    if (backwards) {
        v = BlkValueRead(list, LIST_ITEM_BASE);
        for (i=0:i<no_items-1:i++)
            BlkValueWrite(list, LIST_ITEM_BASE+i,
                BlkValueRead(list, LIST_ITEM_BASE+i+1));
        BlkValueWrite(list, no_items-1+LIST_ITEM_BASE, v);
    } else {
        v = BlkValueRead(list, no_items-1+LIST_ITEM_BASE);
        for (i=no_items-1:i>0:i--)
            BlkValueWrite(list, LIST_ITEM_BASE+i,
                BlkValueRead(list, LIST_ITEM_BASE+i-1));
        BlkValueWrite(list, LIST_ITEM_BASE, v);
    }
    return list;
];
```

§**24. Sorting.** And the same, again, is true of sorting: but we do have to take note of block values when it comes to performing comparisons, because we can only compare items in the list by looking at their contents, not the pointers to their contents.

`LIST_OF_TY_Sort(list, dir, prop)` sorts the given `list` in ascending order if `dir` is 1, in descending order if `dir` is −1, or in random order if `dir` is 2. The comparison used is the one for the kind of value stored in the list, unless the optional argument `prop` is supplied, in which case we sort based not on the item values but on their values for the property `prop`. (This only makes sense if the list contains objects.)

```
[ LIST_OF_TY_Sort list dir prop  i j no_items v;
    no_items = BlkValueRead(list, LIST_LENGTH_F);
    if (dir == 2) {
        if (no_items < 2) return;
        for (i=1:i<no_items:i++) {
            j = random(i+1) - 1;
            v = BlkValueRead(list, LIST_ITEM_BASE+i);
            BlkValueWrite(list, LIST_ITEM_BASE+i, BlkValueRead(list, LIST_ITEM_BASE+j));
            BlkValueWrite(list, LIST_ITEM_BASE+j, v);
        }
        return;
    }
    SetSortDomain(ListSwapEntries, ListCompareEntries);
    SortArray(list, prop, dir, no_items, false, 0);
];
[ ListSwapEntries list i j v;
    if (i==j) return;
    v = BlkValueRead(list, LIST_ITEM_BASE+i-1);
    BlkValueWrite(list, LIST_ITEM_BASE+i-1, BlkValueRead(list, LIST_ITEM_BASE+j-1));
    BlkValueWrite(list, LIST_ITEM_BASE+j-1, v);
];
[ ListCompareEntries list col i j d cf;
    if (i==j) return 0;
    if (I7S_Col) {
        i = BlkValueRead(list, LIST_ITEM_BASE+i-1);
        j = BlkValueRead(list, LIST_ITEM_BASE+j-1);
        if (i provides I7S_Col) i=i.I7S_Col; else i=0;
        if (j provides I7S_Col) j=j.I7S_Col; else j=0;
        return i - j;
    }
    cf = BlkValueRead(list, LIST_ITEM_COMPARE_F);
    if (cf == 0)
        return BlkValueRead(list, LIST_ITEM_BASE+i-1) -
            BlkValueRead(list, LIST_ITEM_BASE+j-1);
    else
        return cf(BlkValueRead(list, LIST_ITEM_BASE+i-1),
            BlkValueRead(list, LIST_ITEM_BASE+j-1));
];
#IFNOT; ! IFDEF MEMORY_HEAP_SIZE
[ LIST_OF_TY_Support t a b c; rfalse; ];

[ LIST_OF_TY_Empty list; rfalse; ];
#ENDIF; ! IFDEF MEMORY_HEAP_SIZE
```

BlockValues Template B/blkvt

Purpose

Routines for copying, comparing, creating and destroying block values, and for reading and writing them as if they were arrays.

---

§**1. Head.** As with Flex.i6t, none of this material is worth compiling unless there is a heap on which the block values can be stored.

```
#IFDEF MEMORY_HEAP_SIZE;
```

§**2. Data Section.** In this segment, we provide a layer which comes between "Flex.i6t" and its eventual users. These are routines which handle the data section for the allocated blocks, and which isolate the end user from having to know how the blocks are divided. As far as the user is concerned, each block value has an "extent" E, and consists of an array of values indexed from 0 to $E-1$. These are bytes unless `BLK_FLAG_WORD` is set in the header, in which case they are words; unless `BLK_FLAG_16_BIT` is set, in which case they are two-byte quantities. (For instance, indexed text is stored using bytes on the Z-machine but 16-bit quantities on Glulx, since the ZSCII character set can fit into the range 0 to 255 but Unicode cannot.)

`BlkValueExtent(B)` returns the value E for the block `B`.

`BlkValueSetExtent(B, N)` resizes the block `B` so that value E is at least `N`. If this is a reduction, entries are lost from the end, i.e., from the highest-indexed entries. If it is an expansion, entries are added at the end and the existing entries are preserved.

`BlkValueRead(B, I)` returns the value of array entry `I` in `B`.

`BlkValueWrite(B, I, V)` puts the value `V` into array entry `I` in `B`.

```
[ BlkValueExtent block  tsize flags;
    if (block == 0) return 0;
    flags = block->BLK_HEADER_FLAGS;
    if (flags & BLK_FLAG_MULTIPLE == 0)
        tsize = BlkSize(block) - BLK_DATA_OFFSET;
    else
        for (:block~=NULL:block=block-->BLK_NEXT)
            tsize = tsize + BlkSize(block) - BLK_DATA_MULTI_OFFSET;
    if (flags & BLK_FLAG_16_BIT) return tsize/2;
    if (flags & BLK_FLAG_WORD) return tsize/WORDSIZE;
    return tsize;
];
[ BlkValueSetExtent block tsize flags wsize;
    if (block == 0) return 0;
    flags = block->BLK_HEADER_FLAGS; wsize = 1;
    if (flags & BLK_FLAG_WORD) wsize = WORDSIZE;
    if (flags & BLK_FLAG_16_BIT) wsize = 2;
    return BlkResize(block, (tsize)*wsize);
];
[ BlkValueRead block pos dsize hsize flags wsize ot op;
    if (block==0) rfalse;
```

```
    flags = block->BLK_HEADER_FLAGS; wsize = 1;
    if (flags & BLK_FLAG_WORD) wsize = WORDSIZE;
    if (flags & BLK_FLAG_16_BIT) wsize = 2;
    ot = block; op = pos;
    pos = pos*wsize;
    if (flags & BLK_FLAG_MULTIPLE) hsize = BLK_DATA_MULTI_OFFSET;
    else hsize = BLK_DATA_OFFSET;
    for (:block~=NULL:block=block-->BLK_NEXT) {
        dsize = BlkSize(block) - hsize;
        if ((pos >= 0) && (pos<dsize)) {
            block = block + hsize + pos;
            switch(wsize) {
                1: return block->0;
                2: #Iftrue (WORDSIZE == 2); return block-->0;
                    #ifnot; return (block->0)*256 + (block->1);
                    #endif;
                4: return block-->0;
            }
        }
        pos = pos - dsize;
    }
    "*** BlkValueRead: reading from index out of range: ", op, " in ", ot, " ***";
];
[ BlkValueWrite block pos val dsize hsize flags wsize ot op;
    if (block==0) rfalse;
    flags = block->BLK_HEADER_FLAGS; wsize = 1;
    if (flags & BLK_FLAG_WORD) wsize = WORDSIZE;
    if (flags & BLK_FLAG_16_BIT) wsize = 2;
    ot = block; op = pos;
    pos = pos*wsize;
    if (flags & BLK_FLAG_MULTIPLE) hsize = BLK_DATA_MULTI_OFFSET;
    else hsize = BLK_DATA_OFFSET;
    for (:block~=NULL:block=block-->BLK_NEXT) {
        dsize = BlkSize(block) - hsize;
        if ((pos >= 0) && (pos<dsize)) {
            block = block + hsize + pos;
            switch(wsize) {
                1: block->0 = val;
                2: #Iftrue (WORDSIZE == 2); block-->0 = val;
                    #ifnot; block->0 = (val/256)%256; block->1 = val%256;
                    #endif;
                4: block-->0 = val;
            }
            return;
        }
        pos = pos - dsize;
    }
    "*** BlkValueWrite: writing to index out of range: ", op, " in ", ot, " ***";
];
```

§**3. KOV Support.** To carry out the four fundamental operations on block values – creating, destroying, copying and comparing – we need to take account of what data they hold. Letting an indexed text go matters little: it contains only character codes. But letting a list of lists of numbers disappear is risky, because we might leave allocated blocks all over the heap for those individual lists of numbers which are now no longer in their parent list. Every KOV has different needs, because every KOV uses its data differently.

Each block KOV, then, provides a single "KOV support" function. These are named systematically by suffixing `_Support`: that is, the support function for `INDEXED_TEXT_TY` is called `INDEXED_TEXT_TY_Support` and so on. NI compiles a function called `KOVSupportFunction` which takes a KOV number as its argument and returns the relevant function.

The support function can be called with any of the following task constants as its first argument: it then has a further one to three arguments depending on the task in hand.

```
Constant CREATE_KOVS     = 1;
Constant CAST_KOVS       = 2;
Constant DESTROY_KOVS    = 3;
Constant PRECOPY_KOVS    = 4;
Constant COPY_KOVS       = 5;
Constant COMPARE_KOVS    = 6;
Constant READ_FILE_KOVS  = 7;
Constant WRITE_FILE_KOVS = 8;
```

§**4. Creation.** To create a new value, we can't simply allocate a block and then fill it in some way appropriate to the kind of value needed: because we don't know what size of block would be a good idea, and even that much depends on the KOV. So the following routine delegates the whole process to the relevant KOV's support routines.

Depending on the KOV, we can also create it with a value cast from some existing value: for instance, an indexed text can be created with a value cast from the ordinary text "Marshmellow".

`K_Support(CREATE_KOVS, cast_from, skov)` – where `cast_from` and `skov` are optional arguments – is called to allocate a block on the heap and, if `cast_from` is non-zero, cast that data into the new block value. Of course `cast_from` itself is a value, and we don't specify its KOV: the support function is expected to know what it will get (if anything). `skov` stands for "secondary kind of value" and is only applicable if `K` is a KOV constructor rather than a base KOV: for instance, if `K` is "list of...", then to create a "list of numbers" we would have `skov` equal to `NUMBER_TY`, whereas to create a "list of lists of texts" `skov` would be `LIST_OF_TY`.

```
Global block_value_tally;
[ BlkValueCreate kov cast_from skov  block sf;
    sf = KOVSupportFunction(kov);
    if (sf) block = sf(CREATE_KOVS, cast_from, skov);
    else { print "*** Impossible runtime creation ***^"; rfalse; }
#ifdef SHOW_ALLOCATIONS;
    print "[created ", kov, " at ", block, ": ", block_value_tally++, "]^";
#endif;
    return block;
];
```

§**5. Casting.** Just as we can create a value with a cast, we can also perform an assignment to an already-created block value in the form of a cast: well, for some kinds of value we can.

`K_Support(CAST_KOVS, fromval, fromkov, block)` casts from a value `fromval` with a specified KOV `fromkov` into the existing block value `block`.

```
[ BlkValueCast block tokov fromkov fromval  sf;
    sf = KOVSupportFunction(tokov);
    if (sf) return sf(CAST_KOVS, fromval, fromkov, block);
    else { print "*** Impossible runtime cast ***^"; rfalse; }
];
```

§**6. Destruction.** This must be called whenever the current contents of a block value is about to be lost, either because of overwriting or because the block value is in a variable which is going out of scope. What must be done depends on the kind of value: for instance, for indexed text nothing need be done, because the array entries only contains character values. But for a list of lists of numbers, for instance, array entries are pointers to lists of numbers. Simply overwriting or forgetting them means that the lists to which they point will be stuck on the heap forever, and will never be deallocated. So value destruction for a list involves destroying each individual entry and then deallocating it: and this may of course recurse.

`K_Support(DESTROY_KOVS, block)` takes whatever action is necessary to ensure that the values remaining in `block` can be discarded without leaving unreferenced data left on the heap.

```
[ BlkValueDestroy block  k rv sf;
    if (block == 0) return;
    k = block-->BLK_HEADER_KOV;
    sf = KOVSupportFunction(k);
    if (sf) return sf(DESTROY_KOVS, block);
    else { print "*** Impossible runtime deallocation ***^"; rfalse; }
];
```

§**7. Deep Copy.** A deep copy transfers the data contents – that is, the arrays described above – from one block to another; the old contents must be destroyed first. Note that we first perform a simplistic copy of the bits over, but that for some block values that won't be good enough. If the two blocks contain lists of lists, then each entry is itself a list, and a deep copy of each entry must also be performed.

`K_Support(COPY_KOVS, blockto, blockfrom)` takes whatever additional action might be necessary to ensure that pointers to heap data are not duplicated; it runs after the raw data has been copied bitwise and may only have to correct a few entries, or even none at all.

```
[ BlkValueCopy blockto blockfrom dsize i sf;
    if (blockto == 0) { print "*** Deep copy failed: destination empty ***^"; rfalse; }
    if (blockfrom == 0) { print "*** Deep copy failed: source empty ***^"; rfalse; }
    if (blockfrom->BLK_HEADER_N == 0) {
        ! A hack to handle precompiled array constants: N=0 blocks otherwise don't exist
        LIST_OF_TY_CopyRawArray(blockto, blockfrom, 1);
        return blockto;
    }
    if (blockfrom-->BLK_HEADER_KOV ~= blockto-->BLK_HEADER_KOV) {
        print "*** Deep copy failed: types mismatch ***^"; rfalse;
    }
    BlkValueDestroy(blockto);
    dsize = BlkValueExtent(blockfrom);
```

```
    if (((blockfrom->BLK_HEADER_FLAGS) & BLK_FLAG_MULTIPLE) &&
        (BlkValueSetExtent(blockto, dsize, -1) == false)) {
        print "*** Deep copy failed: resizing failed ***^"; rfalse;
    }
    sf = KOVSupportFunction(blockfrom-->BLK_HEADER_KOV);
    if (sf) sf(PRECOPY_KOVS, blockto, blockfrom);
    for (i=0:i<dsize:i++) BlkValueWrite(blockto, i, BlkValueRead(blockfrom, i));
    if (sf) sf(COPY_KOVS, blockto, blockfrom);
    else { print "*** Impossible runtime copy ***^"; rfalse; }
    return blockto;
];
```

§**8. Comparison.** And it's a similar story with comparison.

`K_Support(COMPARE_KOVS, blockleft, blockright)` looks at the data in the two blocks and returns 0 if they are equal, a positive number if `blockright` is "greater than" `blockleft`, and a negative number if not. The interpretation of "greater than" depends on the KOV: it should be something which the user would find natural.

```
[ BlkValueCompare blockleft blockright  kov sf;
    if ((blockleft == 0) && (blockright == 0)) return 0;
    if (blockleft == 0) return 1;
    if (blockright == 0) return -1;
    if (blockleft-->BLK_HEADER_KOV ~= blockright-->BLK_HEADER_KOV)
        return blockleft-->BLK_HEADER_KOV - blockright-->BLK_HEADER_KOV;
    kov = blockleft-->BLK_HEADER_KOV;
    sf = KOVSupportFunction(kov);
    if (sf) return sf(COMPARE_KOVS, blockleft, blockright);
    else { print "*** Impossible runtime comparison ***^"; rfalse; }
];
```

§**9. Creating Constants.** If the NI compiler reads, say, the string literal "Sea Devils" in the source text, and it is expecting to find indexed text – for instance if it's in a column of a table marked as containing indexed text – then how is this to find its way into memory as a block value? The heaps starts entirely empty, and NI cannot precompile parts of it: nor would we really want that, since it would hardwire assumptions about the heap's format into NI itself.

The answer is that at start-up time we perform creations of all of the constants we will need. Because they are constants, they will never be deallocated and never change in their contents – so they need not live on the heap at all, and in fact we store them elsewhere in memory. NI simply creates a blank array of the right 2^n size. Suppose that `X` is the address of this array. Then during the start-up rules, we at some point do this:

```
    BlkValueInitialCopy(X, BlkValueCreate(INDEXED_TEXT_TY, "Sea Devils"))
```

The effect is to create a suitable structure on the heap to hold this as indexed text, and then to copy it bitwise into `X`. A bitwise copy is ordinarily against the rules because it duplicates pointers, but of course the created block has been created for this purpose only: nothing points to it, and it is about to vanish – indeed the address of the block in question exists only briefly on the VM stack. (It is because of this that we don't perform a deep copy using the routine above.)

```
[ BlkValueInitialCopy blockto blockfrom dsize i;
    if (blockto == 0) { print "*** Initial copy failed: destination empty ***^"; rfalse; }
    if (blockfrom == 0) { print "*** Initial copy failed: source empty ***^"; rfalse; }
```

```
    dsize = 1; for (i=1: i<=blockfrom->BLK_HEADER_N: i++) dsize=dsize*2;
    for (i=0:i<dsize:i++) blockto->i = blockfrom->i;
    return blockto;
];
```

§**10. Serialisation.** Some block values can be written to external files (on Glulx): others cannot. The following routines abstract that.

If `ch` is −1, then `K_Support(READ_FILE_KOVS, block, auxf, ch)` returns `true` or `false` according to whether it is possible to read data from an auxiliary file `auxf` into the block value `block`. If `ch` is any other value, then the routine should do exactly that, taking `ch` to be the first character of the text read from the file which makes up the serialised form of the data.

`K_Support(WRITE_FILE_KOVS, block)` is simpler because, strictly speaking, it doesn't write to a file at all: it simply prints a serialised form of the data in `block` to the output stream. Since it is called only when that output stream has been redirected to an auxiliary file, and since the serialised form would often be illegible on screen, it seems reasonable to call it a file input-output function just the same.

```
[ BlkValueReadFromFile block auxf ch kov  sf;
    sf = KOVSupportFunction(kov);
    if (sf) return sf(READ_FILE_KOVS, block, auxf, ch);
    rfalse;
];
[ BlkValueWriteToFile block kov  sf;
    sf = KOVSupportFunction(kov);
    if (sf) return sf(WRITE_FILE_KOVS, block);
    rfalse;
];
```

§**11. Stubs.** To ensure that the template code will still compile if `MEMORY_HEAP_SIZE` is undefined and there's no heap: none of these routines do anything in such a situation, but nor are they ever called – it's just that I6 source code may refer to them anyway, so they need to exist as routine names.

```
#IFNOT; ! IFDEF MEMORY_HEAP_SIZE
[ BlkValueReadFromFile; rfalse; ];
[ BlkValueWriteToFile; rfalse; ];
[ BlkValueCreate; ];
[ BlkValueCompare x y; ];
#ENDIF; ! IFDEF MEMORY_HEAP_SIZE
```

Flex Template B/flext

Purpose

To allocate flexible-sized blocks of memory as needed to hold arbitrary-length strings of text, stored actions or other block values.

---

§**1. Overview.** Each I7 value is represented at run-time by an I6 word: on the Z-machine, a 16-bit number, and on Glulx, a 32-bit number. The correspondence between these numbers and the original values depends on the kind of value: "number" comes out as a signed twos-complement number, but "time" as an integer number of minutes since midnight, "rulebook" as the index of the rulebook in order of creation, and so on.

Even if a 32-bit number is available, this is not enough to represent the full range of values we might want: consider all the possible hundred-word essays of text, for instance. In some cases, then, the value is (either directly or indirectly) a pointer, telling the run-time code that the data is not in the value itself but can be found at a given location in memory. For instance, a "text" value is a (packed) address of either some encoded text or a routine to print text. When NI compiles references to a text value, it also creates the data to which this address belongs.

This works well if the data need not change in size, and if we never need to create or throw away values. But if we want a variable which can hold an arbitrary string of text which we will compose for ourselves, say, then we need at run-time to find space somewhere in memory to hold that data, and we need to be able to cope if that space runs out, and lastly we need a way to reclaim the memory again when the text's usefulness has finished. For instance, if a rule uses a temporary "let" variable which will hold indexed text then the block of indexed text data must be allocated; the variable must then be set to a pointer to this data; the rule must then run, and lastly the block of data deallocated again.

Values of this kind are called "block values" since they are pointers to blocks of memory. We have to be careful when making assignments to variables having these kinds of value. In I7, text like "change the motto text to the player's command" must not be compiled to I6 code such as `MT = PC;`, because that simply sets `MT` to have the same address as `PC`. There are now two independent pointers to the same piece of text, so that changing either one would change both, while the previous contents of `MT` are un-pointed to. The latter problem is almost as bad as the former, because it means that memory has been wasted forever – it would never be reclaimed. Repeat the process often enough and all the memory will be lost in this way: this is called a "leak".

I7 treats block values exactly like other values, as far as the writer is concerned. There is no concept of "a pointer to..." in I7 source text. Instead:

(1) For every allocated block of data, there is exactly one I7 value – stored in an I6 local or global variable, in a property, in a table entry, or even as part of another allocated block of data – which points to it.
(2) When assigning `Y` to `X`, we always perform a "deep copy" of the contents of the block pointed to by `Y` into that pointed to by `X`: we never copy pointers, which would be a "shallow copy".
(3) If `X` is the I6 representation of a block kind of value, then `X` is either 0 – meaning "not allocated yet" – or a valid pointer to a block of data. This is purely for efficiency's sake, making table columns of indexed text (for instance) a sparse representation when, as often happens, not many are filled in. When assigning to 0, we must first allocate a block, then change the pointer from 0 to point to it, and assign to the newly-allocated block. The user is oblivious to all of this.
(4) Any value which will be lost – for instance, a value in a variable which goes out of scope – must have its block deallocated first.
(5) Any value which is passed as an argument to a function must be copied first, as otherwise there are two pointers to the same block of data, one in the calling stack frame and the other in the one called;

in other words, we call by value, never by reference. (As we shall see, I7 phrases can indeed by defined which work by reference rather than by value, but those are defined using inline I6, not as function calls.)

As simple as this scheme looks – there is no need for garbage collection or reference counting – it is not entirely easy to get right. There are many complications, but the basic slogan is one pointer, one block.

§**2. Head.** On the Z-machine, though not always on Glulx, the entire heap has to be allocated at compile-time, and we tend to want to make it reasonably large to cover most eventualities (though the heap size is controllable with use options, so the user does have control over this).

Many small works of IF never have need of the heap at all, and at the same time can't spare the memory for it. NI only creates the constant `MEMORY_HEAP_SIZE`, the number of bytes initially given over to the heap, if need arises. So the code and arrays in this segment will never be compiled unless needed (but see also the "Stubs" paragraph below).

```
#IFDEF MEMORY_HEAP_SIZE;
! Constant SHOW_ALLOCATIONS = 1; ! Uncomment this for debugging purposes
```

§**3. Blocks.** A "block" is a continuous range of 2^n bytes of memory, where $n \geq 3$ for a 16-bit VM (i.e., for the Z-machine) and $n \geq 4$ for a 32-bit VM (i.e., on Glulx). Internally, a block is divided into a header followed by a data section.

The header consists of 4, 8 or 16 bytes, depending on the word size and the kind of block (see below). It always begins with a byte specifying n, the binary logarithm of its size: thus the largest block representable is 2^{255} bytes long, but somehow I think we can live with that. The second byte contains a bitmap of (at present) three flags, whose meanings will be explained below. The second *word* of the block, which might be at byte offset 2 or 4 from the start of the block depending on the word-size of the VM, is a number specifying the kind of value (KOV) which the block contains data of.

It might be objected that KOVs are not reducible to simple numbers. For instance, for any KOV K there is another KOV "list of K", so there is an infinite range of possibilities. "List of..." is what, in other languages, would be called a type constructor; whereas a KOV like "indexed text" is what would be called a base type, since it is not the result of any type constructor. In I7, there is a finite range of base types and type constructors, and these have distinct ID numbers: that is what is stored in the `BLK_HEADER_KOV` field. A block which has KOV "list of indexed texts" will have the same value here as a block which has KOV "list of numbers": it will store the I6 constant `LIST_OF_TY`. (To find out whether such a list does indeed contain numbers or texts – and it is essential to be able to do this – one must look at the data section of the block. See "Lists.i6t".)

The data section of a block begins at the byte offset `BLK_DATA_OFFSET` from the address of the block: but see below for how multiple-blocks behave differently.

```
Constant BLK_HEADER_N = 0;
Constant BLK_HEADER_FLAGS = 1;
Constant BLK_FLAG_MULTIPLE = $$00000001;
Constant BLK_FLAG_16_BIT   = $$00000010;
Constant BLK_FLAG_WORD     = $$00000100;
Constant BLK_HEADER_KOV = 1;
Constant BLK_DATA_OFFSET = 2*WORDSIZE;
```

§**4. Multiple Blocks.** There are two kinds of block values: those which can always be stored in a single block (for instance, a floating-point number stored in exactly 8 bytes of data would be suitable for this), and those which can change unpredictably in size and might at any point overflow their current storage, so that they may need to occupy multiple blocks (for instance, an indexed text). In such a multiple-block KOV, the data is stored in a doubly linked list of blocks, and the I6 value for the result is the pointer to the block which heads the linked list. For instance, the indexed text

```
"But now I worship a celestiall Sunne"
```

might be represented by an I6 value `BN` which points to a list of blocks like so:

```
NULL <-- BN: "But now I wor" <--> BN2: "ship a celestiall Sunne" --> NULL
```

Note that the unique pointer to `BN2` is the one in the header of the `BN` block. When we need to grow such a text, we add additional blocks; if the text should shrink, blocks at the end can at our discretion be deallocated. If the entire text should be deallocated, then all of the blocks used for it are deallocated, starting at the back and working towards the front.

A multiple-block is one whose flags byte contains the `BLK_FLAG_MULTIPLE`. This information is redundant since it could in principle be deduced from the kind of value stored in the block, which is recorded in the `-->BLK_HEADER_KOV` word, but that would be too slow. `BLK_FLAG_MULTIPLE` can never change for a currently allocated block, just as it can never change its KOV.

A multiple-block header is longer than that of an ordinary block, because it contains two extra words: `-->BLK_NEXT` is the next block in the doubly-linked list of blocks representing the current value, or `NULL` if this is the end; `-->BLK_PREV` is the previous block, or `NULL` if this is the beginning. The need to fit these two extra words in means that the data section is deferred, and so for a multiple-block data begins at the byte offset `BLK_DATA_MULTI_OFFSET` rather than `BLK_DATA_OFFSET`.

```
Constant BLK_DATA_MULTI_OFFSET = 4*WORDSIZE;
Constant BLK_NEXT 2;
Constant BLK_PREV 3;
```

§**5. Block Routines.**

```
[ BlkType txb;
    return txb-->BLK_HEADER_KOV;
];
[ BlkSize txb bsize n; ! Size of an individual block, including header
    if (txb == 0) return 0;
    for (bsize=1: n<txb->BLK_HEADER_N: bsize=bsize*2) n++;
    return bsize;
];
[ BlkTotalSize txb tsize; ! Combined size of multiple-blocks for a value
    if (txb == 0) return 0;
    if ((txb->BLK_HEADER_FLAGS) & BLK_FLAG_MULTIPLE == 0)
        return BlkSize(txb);
    for (:txb~=NULL:txb=txb-->BLK_NEXT) {
        tsize = tsize + BlkSize(txb);
    }
    return tsize;
];
```

§**6. Debugging Routines.** These two routines are purely for testing the code.

```
[ BlkDebug txb n k i bsize tot dtot kov;
    if (txb == 0) "Block never created.";
    kov = txb-->BLK_HEADER_KOV;
    print "Block ", txb, " (kov ", kov, "): ";
    for (:txb~=NULL:txb = txb-->BLK_NEXT) {
        if (k++ == 100) " ... and so on.";
        if (txb-->BLK_HEADER_KOV ~= kov)
            print "*Wrong kov=", txb-->BLK_HEADER_KOV, "* ";
        n = txb->BLK_HEADER_N;
        for (bsize=1:n>0:n--) bsize=bsize*2;
        i = bsize - BLK_DATA_OFFSET;
        dtot = dtot+i;
        tot = tot+bsize;
        print txb, "(", bsize, ") > ";
    }
    print dtot, " data in ", tot, " bytes^";
];
[ BlkDebugDecomposition from to txb pf;
    if (to==0) to = NULL;
    for (txb=from:(txb~=to) && (txb~=NULL):txb=txb-->BLK_NEXT) {
        if (pf) print "+";
        print BlkSize(txb);
        pf = true;
    }
    print "^";
];
```

§**7. The Heap.** Properly speaking, a "heap" is a specific kind of structure often used for managing uneven-sized or unpredictably changing data. We use "heap" here in the looser sense of being an amorphous-sized collection of blocks of memory, some free, others allocated; our actual representation of free space on the heap is not a heap structure in computer science terms. (Though this segment could easily be rewritten to make it so, or to adopt any other scheme which might be faster, without modifying the rest of the template or NI itself.) The heap begins as a contiguous region of memory, but it need not remain so: on Glulx we use dynamic memory allocation to extend it.

For I7 purposes we don't need a way to represent allocated memory, only the free memory. A block is free if and only if it has `-->BLK_HEADER_KOV` equal to 0, which is never a valid kind of value, and also has the multiple flag set. We do that because we construct the whole collection of free blocks, at any given time, as a single, multiple-block "value": a doubly linked list joined by the `-->BLK_NEXT` and `<--BLK_PREV`.

A single block, at the bottom of memory and never moving, never allocated to anyone, is preserved in order to be the head of this linked list of free blocks. This is a 16-byte (i.e., $n = 4$) block, which we format when the heap is initialised in `HeapInitialise()`. Thus the heap is full if and only if the `-->BLK_NEXT` of the head-free-block is `NULL`.

So far we have described a somewhat lax regime. After many allocations and deallocations one could imagine the list of free blocks becoming a very long list of individually small blocks, which would both make it difficult to allocate large blocks, and also slow to look through the list. To ameliorate matters, we maintain the following invariants:

(a) In the free blocks list, `B-->BLK_NEXT` is always an address after `B`;
(b) For any contiguous run of free space blocks in memory (excluding the head-free-block), taking up a total of T bytes, the last block in the run has size 2^n where n is the largest integer such that $2^n \leq T$.

For instance, there can never be two consecutive free blocks of size 128: they would form a "run" in the sense of rule (b) of size $T = 256$, and when T is a power of two the run must contain a single block. In general, it's easy to prove that the number of blocks in the run is exactly the number of 1s when T is written out as a binary number, and that the blocks are ordered in memory from small to large (the reverse of the direction of reading, i.e., rightmost 1 digit first). Maintaining (b) is a matter of being careful to fragment blocks only from the front when smaller blocks are needed, and to rejoin from the back when blocks are freed and added to the free space object.

```
Array Blk_Heap -> MEMORY_HEAP_SIZE + 16; ! Plus 16 to allow room for head-free-block
```

§**8. Initialisation.** To recap: the constant `MEMORY_HEAP_SIZE` has been predefined by the NI compiler, and is always itself a power of 2, say 2^n. We therefore have $2^n + 2^4$ bytes available to us, and we format these as a free space list of two blocks: the 2^4-sized "head-free-block" described above followed by a 2^n-sized block exactly containing the whole of the rest of the heap.

```
[ HeapInitialise n bsize blk2;
    blk2 = Blk_Heap + 16;
    Blk_Heap->BLK_HEADER_N = 4;
    Blk_Heap-->BLK_HEADER_KOV = 0;
    Blk_Heap->BLK_HEADER_FLAGS = BLK_FLAG_MULTIPLE;
    Blk_Heap-->BLK_NEXT = blk2;
    Blk_Heap-->BLK_PREV = NULL;
    for (bsize=1: bsize < MEMORY_HEAP_SIZE: bsize=bsize*2) n++;
    blk2->BLK_HEADER_N = n;
    blk2-->BLK_HEADER_KOV = 0;
    blk2->BLK_HEADER_FLAGS = BLK_FLAG_MULTIPLE;
    blk2-->BLK_NEXT = NULL;
    blk2-->BLK_PREV = Blk_Heap;
];
```

§**9. Net Free Space.** "Net" in the sense of "after deductions for the headers": this is the actual number of free bytes left on the heap which could be used for data. Note that it is used to predict whether it is possible to fit something further in: so there are two answers, depending on whether the something is multiple-block data (with a larger header and therefore less room for data) or single-block data (smaller header, more room).

```
[ HeapNetFreeSpace multiple txb asize;
    for (txb=Blk_Heap-->BLK_NEXT: txb~=NULL: txb=txb-->BLK_NEXT) {
        asize = asize + BlkSize(txb);
        if (multiple) asize = asize - BLK_DATA_MULTI_OFFSET;
        else asize = asize - BLK_DATA_OFFSET;
    }
    return asize;
];
```

§**10. Make Space.** The following routine determines if there is enough free space to accommodate another `size` bytes of data, given that it has to be multiple-block data if the `multiple` flag is set. If the answer turns out to be "no", we see if the host virtual machine is able to allocate more for us: if it is, then we ask for 2^m further bytes, where 2^m is at least `size` plus the worst-case header storage requirement (16 bytes), and in addition is large enough to make it worth while allocating. We don't want to bother the VM by asking for trivial amounts of memory.

This looks to be more memory than is needed, since after all we've asked for enough that the new data can fit entirely into the new block allocated, and we might have been able to squeeze some of it into the existing free space. But it ensures that heap invariant (b) above is preserved, and besides, running out of memory tends to be something you don't do only once.

(The code below is a refinement on the original, suggested by Jesse McGrew, which handles non-multiple blocks better.)

```
Constant SMALLEST_BLK_WORTH_ALLOCATING = 12; ! i.e. 2^12 = 4096 bytes

[ HeapMakeSpace size multiple  newblocksize newblock B n;
    for (::) {
        if (multiple) {
            if (HeapNetFreeSpace(multiple) >= size) rtrue;
        } else {
            if (HeapLargestFreeBlock(0) >= size) rtrue;
        }
        newblocksize = 1;
        for (n=0: (n<SMALLEST_BLK_WORTH_ALLOCATING) || (newblocksize<size): n++)
            newblocksize = newblocksize*2;
        while (newblocksize < size+16) newblocksize = newblocksize*2;
        newblock = VM_AllocateMemory(newblocksize);
        if (newblock == 0) rfalse;
        newblock->BLK_HEADER_N = n;
        newblock-->BLK_HEADER_KOV = 0;
        newblock->BLK_HEADER_FLAGS = BLK_FLAG_MULTIPLE;
        newblock-->BLK_NEXT = NULL;
        newblock-->BLK_PREV = NULL;
        for (B = Blk_Heap-->BLK_NEXT:B ~= NULL:B = B-->BLK_NEXT)
            if (B-->BLK_NEXT == NULL) {
                B-->BLK_NEXT = newblock;
                newblock-->BLK_PREV = B;
                jump Linked;
            }
        Blk_Heap-->BLK_NEXT = newblock;
        newblock-->BLK_PREV = Blk_Heap;
        .Linked; ;
        #ifdef SHOW_ALLOCATIONS;
        print "Increasing heap to free space map: "; BlkDebugDecomposition(Blk_Heap, 0);
        #endif;
    }
    rtrue;
];

[ HeapLargestFreeBlock multiple txb asize best;
    best = 0;
    for (txb=Blk_Heap-->BLK_NEXT: txb~=NULL: txb=txb-->BLK_NEXT) {
        asize = BlkSize(txb);
        if (multiple) asize = asize - BLK_DATA_MULTI_OFFSET;
```

```
        else asize = asize - BLK_DATA_OFFSET;
        if (asize > best) best = asize;
    }
    return best;
];
```

§**11. Block Allocation.** The routine `BlkAllocate(N, K, F)` allocates a block with room for `size` net bytes of data, which will have kind of value `K` and with flags `F`. If the flags include `BLK_FLAG_MULTIPLE`, this may be either a list of blocks or a single block. It returns either the address of the block or else throws run-time problem message and returns 0.

In allocation, we try to find a block which is as close as possible to the right size, and we may have to subdivide blocks: see case II below. For instance, if a block of size 2^n is available and we only need a block of size 2^k where $k < n$ then we break it up in memory as a sequence of blocks of size $2^k, 2^k, 2^{k+1}, 2^{k+2}, ..., 2^{n-1}$: note that the sum of these sizes is the 2^n we started with. We then use the first block of size 2^k. To continue the comparison with binary arithmetic, this is like a subtraction with repeated carries:

$$10000000_2 - 00001000_2 = 01111000_2$$

```
[ BlkAllocate size kov flags
    dsize n m free_block min_m max_m smallest_oversized_block secondhalf i hsize head tail;
    if (HeapMakeSpace(size, flags & BLK_FLAG_MULTIPLE) == false)
        return BlkAllocationError("ran out");
    ! Calculate the header size for a block of this KOV
    if (flags & BLK_FLAG_MULTIPLE) hsize = BLK_DATA_MULTI_OFFSET;
    else hsize = BLK_DATA_OFFSET;
    ! Calculate the data size
    n=0; for (dsize=1: dsize < hsize+size: dsize=dsize*2) n++;
    ! Seek a free block closest to the correct size, but starting from the
    ! block after the fixed head-free-block, which we can't touch
    min_m = 10000; max_m = 0;
    for (free_block = Blk_Heap-->BLK_NEXT:
        free_block ~= NULL:
        free_block = free_block-->BLK_NEXT) {
        m = free_block->BLK_HEADER_N;
        ! Current block the ideal size
        if (m == n) jump CorrectSizeFound;
        ! Current block too large: find the smallest which is larger than needed
        if (m > n) {
            if (min_m > m) {
                min_m = m;
                smallest_oversized_block = free_block;
            }
        }
        ! Current block too small: find the largest which is smaller than needed
        if (m < n) {
            if (max_m < m) {
                max_m = m;
            }
        }
    }
    if (min_m == 10000) {
```

```
    ! Case I: No block is large enough to hold the entire size
    if (flags & BLK_FLAG_MULTIPLE == 0) return BlkAllocationError("too fragmented");
    ! Set dsize to the size in bytes if the largest block available
    for (dsize=1: max_m > 0: dsize=dsize*2) max_m--;
    ! Split as a head (dsize-hsize), which we can be sure fits into one block,
    ! plus a tail (size-(dsize-hsize), which might be a list of blocks
    head = BlkAllocate(dsize-hsize, kov, flags);
    if (head == 0) return BlkAllocationError("head block not available");
    tail = BlkAllocate(size-(dsize-hsize), kov, flags);
    if (tail == 0) return BlkAllocationError("tail block not available");
    head-->BLK_NEXT = tail;
    tail-->BLK_PREV = head;
    return head;
}
! Case II: No block is the right size, but some exist which are too big
! Set dsize to the size in bytes of the smallest oversized block
for (dsize=1,m=1: m<=min_m: dsize=dsize*2) m++;
free_block = smallest_oversized_block;
while (min_m > n) {
    ! Repeatedly halve free_block at the front until the two smallest
    ! fragments left are the correct size: then take the frontmost
    dsize = dsize/2;
    secondhalf = free_block + dsize;
    secondhalf-->BLK_NEXT = free_block-->BLK_NEXT;
    if (secondhalf-->BLK_NEXT ~= NULL)
        (secondhalf-->BLK_NEXT)-->BLK_PREV = secondhalf;
    secondhalf-->BLK_PREV = free_block;
    free_block-->BLK_NEXT = secondhalf;
    free_block->BLK_HEADER_N = (free_block->BLK_HEADER_N) - 1;
    secondhalf->BLK_HEADER_N = free_block->BLK_HEADER_N;
    secondhalf-->BLK_HEADER_KOV = free_block-->BLK_HEADER_KOV;
    secondhalf->BLK_HEADER_FLAGS = free_block->BLK_HEADER_FLAGS;
    min_m--;
}
! Once that is done, free_block points to a block which is exactly the
! right size, so we can fall into...
! Case III: There is a free block which has the correct size.
.CorrectSizeFound;
! Delete the free block from the double linked list of free blocks: note
! that it cannot be the head of this list, which is fixed
if (free_block-->BLK_NEXT == NULL) {
    ! We remove final block, so previous is now final
    (free_block-->BLK_PREV)-->BLK_NEXT = NULL;
} else {
    ! We remove a middle block, so join previous to next
    (free_block-->BLK_PREV)-->BLK_NEXT = free_block-->BLK_NEXT;
    (free_block-->BLK_NEXT)-->BLK_PREV = free_block-->BLK_PREV;
}
free_block-->BLK_HEADER_KOV = kov;
free_block->BLK_HEADER_FLAGS = flags;
if (flags & BLK_FLAG_MULTIPLE) {
    free_block-->BLK_NEXT = NULL;
    free_block-->BLK_PREV = NULL;
```

```
    }
    ! Zero out the data bytes in the memory allocated
    for (i=hsize:i<dsize:i++) free_block->i=0;
    return free_block;
];
[ BlkAllocationError reason;
    print "*** Memory ", (string) reason, " ***^";
    RunTimeProblem(RTP_HEAPERROR);
    rfalse;
];
```

§**12. Merging.** Given a free block `block`, find the maximal contiguous run of free blocks which contains it, and then call `BlkRecut` to recut it to conform to invariant (b) above.

```
[ BlkMerge block first last pv nx;
    first = block; last = block;
    while (last-->BLK_NEXT == last+BlkSize(last))
        last = last-->BLK_NEXT;
    while ((first-->BLK_PREV + BlkSize(first-->BLK_PREV) == first) &&
        (first-->BLK_PREV ~= Blk_Heap))
        first = first-->BLK_PREV;
    pv = first-->BLK_PREV;
    nx = last-->BLK_NEXT;
    #ifdef SHOW_ALLOCATIONS;
    print "Merging: "; BlkDebugDecomposition(pv-->BLK_NEXT, nx); print "^";
    #endif;
    if (BlkRecut(first, last)) {
        #ifdef SHOW_ALLOCATIONS;
        print " --> "; BlkDebugDecomposition(pv-->BLK_NEXT, nx); print "^";
        #endif;
    }
];
```

§**13. Recutting.** Given a segment of the free block list, containing blocks known to be contiguous in memory, we recut into a sequence of blocks satisfying invariant (b): we repeatedly cut the largest 2^m-sized chunk off the back end until it is all used up.

```
[ BlkRecut first last tsize backsize mfrom mto bnext backend n dsize fine_so_far;
    if (first == last) rfalse;
    mfrom = first; mto = last + BlkSize(last);
    bnext = last-->BLK_NEXT;
    fine_so_far = true;
    for (:mto>mfrom: mto = mto - backsize) {
        for (n=0, backsize=1: backsize*2 <= mto-mfrom: n++) backsize=backsize*2;
        if ((fine_so_far) && (backsize == BlkSize(last))) {
            bnext = last; last = last-->BLK_PREV;
            bnext-->BLK_PREV = last;
            last-->BLK_NEXT = bnext;
            continue;
        }
        fine_so_far = false; ! From this point, "last" is meaningless
        backend = mto - backsize;
```

```
        backend->BLK_HEADER_N = n;
        backend-->BLK_HEADER_KOV = 0;
        backend->BLK_HEADER_FLAGS = BLK_FLAG_MULTIPLE;
        backend-->BLK_NEXT = bnext;
        if (bnext ~= NULL) {
            bnext-->BLK_PREV = backend;
            bnext = backend;
        }
    }
    if (fine_so_far) rfalse;
    rtrue;
];
```

§**14. Deallocation.** There are two complications: first, when we free a multiple block we need to free all of the blocks in the list, starting from the back end and working forwards to the front – this is the job of `BlkFree`. Second, when any given block is freed it has to be put into the free block list at the correct position to preserve invariant (a): it might either come after all of the currently free blocks in memory, and have to be added to the end of the list, or in between two, and have to be inserted mid-list, but it can't be before all of them because the head-free-block is kept lowest in memory of all possible blocks. (Note that Glulx can't allocate memory dynamically which undercuts the ordinary array space created by I6: I6 arrays fill up memory from the bottom.)

```
[ BlkFree block fromtxb ptxb;
    if (block == 0) return;
    BlkValueDestroy(block);
    if ((block->BLK_HEADER_FLAGS) & BLK_FLAG_MULTIPLE) {
        if (block-->BLK_PREV ~= NULL) (block-->BLK_PREV)-->BLK_NEXT = NULL;
        fromtxb = block;
        for (:(block-->BLK_NEXT)~=NULL:block = block-->BLK_NEXT) ;
        while (block ~= fromtxb) {
            ptxb = block-->BLK_PREV; BlkFreeSingleBlock(block); block = ptxb;
        }
    }
    BlkFreeSingleBlock(block);
];
[ BlkFreeSingleBlock block free nx;
    block-->BLK_HEADER_KOV = 0;
    block->BLK_HEADER_FLAGS = BLK_FLAG_MULTIPLE;
    for (free = Blk_Heap:free ~= NULL:free = free-->BLK_NEXT) {
        nx = free-->BLK_NEXT;
        if (nx == NULL) {
            free-->BLK_NEXT = block;
            block-->BLK_PREV = free;
            block-->BLK_NEXT = NULL;
            BlkMerge(block);
            return;
        }
        if (UnsignedCompare(nx, block) == 1) {
            free-->BLK_NEXT = block;
            block-->BLK_PREV = free;
            block-->BLK_NEXT = nx;
            nx-->BLK_PREV = block;
```

```
            BlkMerge(block);
            return;
        }
    }
];
```

§**15. Resizing.** When the content of a value stretches or shrinks, we will sometimes need to change the size of the block(s) containing the data – though not always: we might sometimes need to resize a 1052-byte text to a 1204-byte text and find that we are sitting in a 2048-byte block in any case. We either shed blocks from the end of the chain, or add new blocks at the end, that being the simplest thing to do. Sometimes it might mean preserving a not very efficient block division, but it minimises the churn of blocks being allocated and freed, which is probably good.

```
[ BlkResize block req newsize dsize newblk kov n i otxb flags;
    if (block == 0) "*** Cannot resize null block ***";
    kov = block-->BLK_HEADER_KOV;
    flags = block->BLK_HEADER_FLAGS;
    if (flags & BLK_FLAG_MULTIPLE == 0) "*** Cannot resize inextensible block ***";
    otxb = block;
    newsize = req;
    for (:: block = block-->BLK_NEXT) {
        n = block->BLK_HEADER_N;
        for (dsize=1: n>0: n--) dsize = dsize*2;
        i = dsize - BLK_DATA_MULTI_OFFSET;
        newsize = newsize - i;
        if (newsize > 0) {
            if (block-->BLK_NEXT ~= NULL) continue;
            newblk = BlkAllocate(newsize, kov, flags);
            if (newblk == 0) rfalse;
            block-->BLK_NEXT = newblk;
            newblk-->BLK_PREV = block;
            rtrue;
        }
        if (block-->BLK_NEXT ~= NULL) {
            BlkFree(block-->BLK_NEXT);
            block-->BLK_NEXT = NULL;
        }
        rtrue;
    }
];
[ DebugHeap;
    print "Managing a heap of initially ", MEMORY_HEAP_SIZE+16, " bytes.^";
    print HeapNetFreeSpace(false), " bytes currently free.^";
    print "Free space decomposition: "; BlkDebugDecomposition(Blk_Heap);
    print "Free space map: "; BlkDebug(Blk_Heap);
];
```

§**16. Stubs.** To ensure that the template code will still compile if `MEMORY_HEAP_SIZE` is undefined and there's no heap: none of these routines do anything in such a situation, but nor are they ever called – it's just that I6 source code may refer to them anyway, so they need to exist as routine names.

```
#IFNOT; ! IFDEF MEMORY_HEAP_SIZE
[ HeapInitialise; ];
[ BlkFree; ];
[ DebugHeap;
    "This story file does not use a heap of managed memory.";
];
#ENDIF; ! IFDEF MEMORY_HEAP_SIZE
```

ZMachine Template B/zmt

Purpose

To provide routines handling low-level Z-machine facilities.

---

§**1. Summary.** This segment closely parallels "Glulx.i6t", which provides exactly equivalent functionality (indeed, usually the same-named functions and in the same order) for the Glulx VM. This is intended to make the rest of the template code independent of the choice of VM, although that is more of an ideal than a reality, because there are so many fiddly differences in some of the grammar and dictionary tables that it is not really practical for the parser (for instance) to call VM-neutral routines to get the data it wants out of these arrays.

§2. Variables and Arrays.

```
Global top_object; ! largest valid number of any tree object
Global xcommsdir; ! true if command recording is on
Global transcript_mode; ! true if game scripting is on

Constant INPUT_BUFFER_LEN = 120; ! Length of buffer array

Array  buffer    -> 123;            ! Buffer for parsing main line of input
Array  buffer2   -> 123;            ! Buffers for supplementary questions
Array  buffer3   -> 123;            ! Buffer retaining input for "again"
Array  parse     buffer 63;         ! Parse table mirroring it
Array  parse2    buffer 63;         !

Global dict_start;
Global dict_entry_size;
Global dict_end;
```

§**3. Starting Up.** `VM_Initialise()` is almost the first routine called, except that the "starting the virtual machine" activity is allowed to go first.

```
[ VM_Initialise;
    standard_interpreter = HDR_TERPSTANDARD-->0;
    transcript_mode = ((HDR_GAMEFLAGS-->0) & 1);

    dict_start = HDR_DICTIONARY-->0;
    dict_entry_size = dict_start->(dict_start->0 + 1);
    dict_start = dict_start + dict_start->0 + 4;
    dict_end = dict_start + ((dict_start - 2)-->0) * dict_entry_size;

    buffer->0  = INPUT_BUFFER_LEN;
    buffer2->0 = INPUT_BUFFER_LEN;
    buffer3->0 = INPUT_BUFFER_LEN;
    parse->0   = 15;
    parse2->0  = 15;

    top_object = #largest_object-255;

    #ifdef FIX_RNG;
    @random 10000 -> i;
    i = -i-2000;
    print "[Random number generator seed is ", i, "]^";
    @random i -> i;
    #endif; ! FIX_RNG
];
```

§**4. Enable Acceleration.** This rule enables use of March 2009 extension to Glulx which optimises the speed of Inform-compiled story files, so for the Z-machine it has no effect.

```
[ ENABLE_GLULX_ACCEL_R;
    rfalse;
];
```

§**5. Release Number.** Like all software, IF story files have release numbers to mark revised versions being circulated: unlike most software, and partly for traditional reasons, the version number is recorded not in some print statement or variable but is branded on, so to speak, in a specific memory location of the story file header.

`VM_Describe_Release()` describes the release and is used as part of the "banner", IF's equivalent to a title page.

```
[ VM_Describe_Release i;
    print "Release ", (HDR_GAMERELEASE-->0) & $03ff, " / Serial number ";
    for (i=0 : i<6 : i++) print (char) HDR_GAMESERIAL->i;
];
```

§**6. Keyboard Input.** The VM must provide three routines for keyboard input:

(a) `VM_KeyChar()` waits for a key to be pressed and then returns the character chosen as a ZSCII character.
(b) `VM_KeyDelay(N)` waits up to $N/10$ seconds for a key to be pressed, returning the ZSCII character if so, or 0 if not.
(c) `VM_ReadKeyboard(b, t)` reads a whole newline-terminated command into the buffer `b`, then parses it into a word stream in the table `t`.

There are elaborations to due with mouse clicks, but this isn't the place to document all of that.

```
[ VM_KeyChar win  key;
    if (win) @set_window win;
    @read_char 1 -> key;
    return key;
];
[ VM_KeyDelay tenths  key;
    @read_char 1 tenths VM_KeyDelay_Interrupt -> key;
    return key;
];
[ VM_KeyDelay_Interrupt; rtrue; ];
[ VM_ReadKeyboard  a_buffer a_table i;
    read a_buffer a_table;
    #ifdef ECHO_COMMANDS;
    print "** ";
    for (i=2: i<=(a_buffer->1)+1: i++) print (char) a_buffer->i;
    print "^";
    #ifnot;
    i=0;  ! suppress compiler warning
    #endif;
    #Iftrue (#version_number == 6);
    @output_stream -1;
    @loadb a_buffer 1 -> sp;
    @add a_buffer 2 -> sp;
    @print_table sp sp;
    new_line;
    @output_stream 1;
    #Endif;
];
```

§**7. Buffer Functions.** A "buffer", in this sense, is an array containing a stream of characters typed from the keyboard; a "parse buffer" is an array which resolves this into individual words, pointing to the relevant entries in the dictionary structure. Because each VM has its own format for each of these arrays (not to mention the dictionary), we have to provide some standard operations needed by the rest of the template as routines for each VM.

The Z-machine buffer and parse buffer formats are documented in the DM4.

`VM_CopyBuffer(to, from)` copies one buffer into another.

`VM_Tokenise(buff, parse_buff)` takes the text in the buffer `buff` and produces the corresponding data in the parse buffer `parse_buff` – this is called tokenisation since the characters are divided into words: in traditional computing jargon, such clumps of characters treated syntactically as units are called tokens.

`LTI_Insert` is documented in the DM4 and the `LTI` prefix stands for "Language To Informese": it's used only by translations into non-English languages of play, and is not called in the template.

```
[ VM_CopyBuffer bto bfrom i;
    for (i=0: i<INPUT_BUFFER_LEN: i++) bto->i = bfrom->i;
];
[ VM_PrintToBuffer buf len a b c;
    @output_stream 3 buf;
    switch (metaclass(a)) {
        String: print (string) a;
        Routine: a(b, c);
        Object, Class: if (b) PrintOrRun(a, b, true); else print (name) a;
    }
    @output_stream -3;
    if (buf-->0 > len) print "Error: Overflow in VM_PrintToBuffer.^";
    return buf-->0;
];
[ VM_Tokenise b p; b->(2 + b->1) = 0; @tokenise b p; ];
[ LTI_Insert i ch  b y;
    ! Protect us from strict mode, as this isn't an array in quite the
    ! sense it expects
    b = buffer;
    ! Insert character ch into buffer at point i.
    ! Being careful not to let the buffer possibly overflow:
    y = b->1;
    if (y > b->0) y = b->0;
    ! Move the subsequent text along one character:
    for (y=y+2 : y>i : y--) b->y = b->(y-1);
    b->i = ch;
    ! And the text is now one character longer:
    if (b->1 < b->0) (b->1)++;
];
```

§**8. Dictionary Functions.** Again, the dictionary structure is differently arranged on the different VMs. This is a data structure containing, in compressed form, the text of all the words to be recognised by tokenisation (above). In I6 for Z, a dictionary word value is represented at run-time by its record number in the dictionary, 0, 1, 2, ..., in alphabetical order.

`VM_InvalidDictionaryAddress(A)` tests whether `A` is a valid record address in the dictionary data structure.

`VM_DictionaryAddressToNumber(A)` and `VM_NumberToDictionaryAddress(N)` convert between record numbers and dictionary addresses.

```
[ VM_InvalidDictionaryAddress addr;
    if ((UnsignedCompare(addr, dict_start) < 0) ||
        (UnsignedCompare(addr, dict_end) >= 0) ||
        ((addr - dict_start) % dict_entry_size ~= 0)) rtrue;
    rfalse;
];
[ VM_DictionaryAddressToNumber w; return (w-(HDR_DICTIONARY-->0 + 7))/9; ];
[ VM_NumberToDictionaryAddress n; return HDR_DICTIONARY-->0 + 7 + 9*n; ];
```

§**9. Command Tables.** The VM is also generated containing a data structure for the grammar produced by I6's `Verb` and `Extend` directives: this is essentially a list of command verbs such as DROP or PUSH, together with a list of synonyms, and then the grammar for the subsequent commands to be recognised by the parser.

```
[ VM_CommandTableAddress i;
    return (HDR_STATICMEMORY-->0)-->i;
];
[ VM_PrintCommandWords i da j;
    da = HDR_DICTIONARY-->0;
    for (j=0 : j<(da+5)-->0 : j++)
        if (da->(j*9 + 14) == $ff-i)
            print "'", (address) VM_NumberToDictionaryAddress(j), "' ";
];
```

§**10. SHOWVERB support.** Further VM-specific tables cover actions and attributes, and these are used by the SHOWVERB testing command.

```
#Ifdef DEBUG;
[ DebugAction a anames;
    if (a >= 4096) { print "<fake action ", a-4096, ">"; return; }
    anames = #identifiers_table;
    anames = anames + 2*(anames-->0) + 2*48;
    print (string) anames-->a;
];
[ DebugAttribute a anames;
    if (a < 0 || a >= 48) print "<invalid attribute ", a, ">";
    else {
        anames = #identifiers_table; anames = anames + 2*(anames-->0);
        print (string) anames-->a;
    }
];
#Endif;
```

§**11. RNG.** No routine is needed for extracting a random number, since I6's built-in `random` function does that, but it's useful to abstract the process of seeding the RNG so that it produces a repeatable sequence of "random" numbers from here on: the necessary opcodes are different for the two VMs.

```
[ VM_Seed_RNG n;
    if (n > 0) n = -n;
    @random n -> n;
];
```

§**12. Memory Allocation.** This is dynamic memory allocation: something which is never practicable in the Z-machine, because the whole address range is already claimed, but which is viable on recent revisions of Glulx.

```
[ VM_AllocateMemory amount;
    return 0;
];
[ VM_FreeMemory address;
];
```

§**13. Audiovisual Resources.** The Z-machine only barely supports figures and sound effects. I7 only allows us to use them for Version 6 of the Z-machine, even though sound effects have a longer pedigree and Infocom used them on some version 5 and even some version 3 works: really, though, from an I7 point of view we would prefer that anyone needing figures and sounds use Glulx instead.

```
[ VM_Picture resource_ID;
    #IFTRUE #version_number == 6; ! Z-machine version 6
    @draw_picture resource_ID;
    #ENDIF;
];
[ VM_SoundEffect resource_ID;
    #IFTRUE #version_number == 6; ! Z-machine version 6
    @sound_effect resource_ID;
    #ENDIF;
];
```

§**14. Typography.** Relatively few typographic effects are available on the Z-machine, so that many of the semantic markups for text which would be distinguishable on Glulx are indistinguishable here.

```
[ VM_Style sty;
    switch (sty) {
        NORMAL_VMSTY, NOTE_VMSTY: style roman;
        HEADER_VMSTY, SUBHEADER_VMSTY, ALERT_VMSTY: style bold;
    }
];
```

§**15. Character Casing.** The following are the equivalent of `tolower` and `toupper`, the traditional C library functions for forcing letters into lower and upper case form, for the ZSCII character set.

```
[ VM_UpperToLowerCase c;
switch (c) {
    'A' to 'Z': c = c + 32;
    202, 204, 212, 214, 221: c--;
    217, 218: c = c - 2;
    158 to 160, 167 to 169, 208 to 210: c = c - 3;
    186 to 190, 196 to 200: c = c - 5 ;
    175 to 180: c = c - 6;
}
return c;
];
[ VM_LowerToUpperCase c;
switch (c) {
    'a' to 'z': c = c - 32;
    201, 203, 211, 213, 220: c++;
    215, 216: c = c + 2;
    155 to 157, 164 to 166, 205 to 207: c = c + 3;
    181 to 185, 191 to 195: c = c + 5 ;
    169 to 174: c = c + 6;
}
return c;
];
```

§**16. The Screen.** Our generic screen model is that the screen is made up of windows: we tend to refer only to two of these, the main window and the status line, but others may also exist from time to time. Windows have unique ID numbers: the special window ID -1 means "all windows" or "the entire screen", which usually amounts to the same thing.

Screen height and width are measured in characters, with respect to the fixed-pitch font used for the status line. The main window normally contains variable-pitch text which may even have been kerned, and character dimensions make little sense there.

Clearing all windows (`WIN_ALL` here) has the side-effect of collapsing the status line, so we need to ensure that `statuswin_cursize` is reduced to 0, in order to keep it accurate.

```
[ VM_ClearScreen window;
    switch (window) {
        WIN_ALL:    @erase_window -1; statuswin_cursize = 0;
        WIN_STATUS: @erase_window 1;
        WIN_MAIN:   @erase_window 0;
    }
];
#Iftrue (#version_number == 6);
[ VM_ScreenWidth  width charw;
    @get_wind_prop 1 3 -> width;
    @get_wind_prop 1 13 -> charw;
    charw = charw & $FF;
    return (width+charw-1) / charw;
];
#Ifnot;
[ VM_ScreenWidth; return (HDR_SCREENWCHARS->0); ];
```

```
#Endif;
[ VM_ScreenHeight; return (HDR_SCREENHLINES->0); ];
```

§**17. Window Colours.** Each window can have its own foreground and background colours.

The colour of individual letters or words of type is not controllable in Glulx, to the frustration of many, and so the template layer of I7 has no framework for handling this (even though it is controllable on the Z-machine, which is greatly superior in this respect).

```
[ VM_SetWindowColours f b window;
    if (clr_on && f && b) {
        if (window == 0) {  ! if setting both together, set reverse
            clr_fgstatus = b;
            clr_bgstatus = f;
            }
        if (window == 1) {
            clr_fgstatus = f;
            clr_bgstatus = b;
        }
        if (window == 0 or 2) {
            clr_fg = f;
            clr_bg = b;
        }
        if (statuswin_current)
            @set_colour clr_fgstatus clr_bgstatus;
        else
            @set_colour clr_fg clr_bg;
    }
];
[ VM_RestoreWindowColours; ! compare I6 library patch L61007
    if (clr_on) { ! check colour has been used
        VM_SetWindowColours(clr_fg, clr_bg, 2); ! make sure both sets of variables are restored
        VM_SetWindowColours(clr_fgstatus, clr_bgstatus, 1, true);
        VM_ClearScreen();
    }
    #Iftrue (#version_number == 6); ! request screen update
    (0-->8) = (0-->8) | $$00000100;
    #Endif;
];
```

§**18. Main Window.** The part of the screen on which commands and responses are printed, which ordinarily occupies almost all of the screen area.

`VM_MainWindow()` switches printing back from another window, usually the status line, to the main window. Note that the Z-machine implementation emulates the Glulx model of window rather than text colours.

```
[ VM_MainWindow;
    if (statuswin_current) {
        if (clr_on && clr_bgstatus > 1) @set_colour clr_fg clr_bg;
        else style roman;
        @set_window 0;
    }
    statuswin_current = false;
];
```

§**19. Status Line.** Despite the name, the status line need not be a single line at the top of the screen: that's only the conventional default arrangement. It can expand to become the equivalent of an old-fashioned VT220 terminal, with menus and grids and mazes displayed lovingly in character graphics, or it can close up to invisibility.

`VM_StatusLineHeight(n)` sets the status line to have a height of `n` lines of type. (The width of the status line is always the width of the whole screen, and the position is always at the top, so the height is the only controllable aspect.) The $n = 0$ case makes the status line disappear.

`VM_MoveCursorInStatusLine(x, y)` switches printing to the status line, positioning the "cursor" – the position at which printing will begin – at the given character grid position (x, y). Line 1 represents the top line; line 2 is underneath, and so on; columns are similarly numbered from 1 at the left.

```
[ VM_MoveCursorInStatusLine line column; ! 1-based position on text grid
    if (~~statuswin_current) {
        @set_window 1;
        if (clr_on && clr_bgstatus > 1) @set_colour clr_fgstatus clr_bgstatus;
        else                            style reverse;
    }
    if (line == 0) {
        line = 1;
        column = 1;
    }
    #Iftrue (#version_number == 6);
    Z6_MoveCursor(line, column);
    #Ifnot;
    @set_cursor line column;
    #Endif;
    statuswin_current = true;
];
#Iftrue (#version_number == 6);
[ Z6_MoveCursor line column  charw charh; ! 1-based position on text grid
    @get_wind_prop 1 13 -> charw; ! font size
    @log_shift charw $FFF8 -> charh;
    charw = charw / $100;
    line = 1 + charh*(line-1);
    column = 1 + charw*(column-1);
    @set_cursor line column;
];
#Endif;
```

```
#Iftrue (#version_number == 6);
[ VM_StatusLineHeight height  wx wy x y charh;
    ! Split the window. Standard 1.0 interpreters should keep the window 0
    ! cursor in the same absolute position, but older interpreters,
    ! including Infocom's don't - they keep the window 0 cursor in the
    ! same position relative to its origin. We therefore compensate
    ! manually.
    @get_wind_prop 0 0 -> wy; @get_wind_prop 0 1 -> wx;

];
#Endif;
```

§**20. Quotation Boxes.** No routine is needed to produce quotation boxes: the I6 `box` statement generates the necessary Z-machine opcodes all by itself.

§**21. Undo.** These simply wrap the relevant opcodes.

```
[ VM_Undo result_code;
    @restore_undo result_code;
    return result_code;
];
[ VM_Save_Undo result_code;
    @save_undo result_code;
    return result_code;
];
```

§**22. Quit The Game Rule.**

```
[ QUIT_THE_GAME_R; if (actor ~= player) rfalse;
    GL__M(##Quit,2); if (YesOrNo()~=0) quit; ];
```

§**23. Restart The Game Rule.**

```
[ RESTART_THE_GAME_R;
    if (actor ~= player) rfalse;
    GL__M(##Restart,1);
    if (YesOrNo()~=0) { @restart; GL__M(##Restart,2); }
];
```

§**24. Restore The Game Rule.**

```
[ RESTORE_THE_GAME_R;
    if (actor ~= player) rfalse;
    restore Rmaybe;
    return GL__M(##Restore,1);
    .RMaybe; GL__M(##Restore,2);
];
```

§25. Save The Game Rule.

```
[ SAVE_THE_GAME_R flag;
    if (actor ~= player) rfalse;
    #IFV5;
    @save -> flag;
    switch (flag) {
        0: GL__M(##Save,1);
        1: GL__M(##Save,2);
        2: GL__M(##Restore,2);
    }
    #IFNOT;
    save Smaybe;
    return GL__M(##Save,1);
    .SMaybe; GL__M(##Save,2);
    #ENDIF;
];
```

§26. Verify The Story File Rule. This is a fossil now, really, but in the days of Infocom, the 110K story file occupying an entire disc was a huge data set: floppy discs were by no means a reliable medium, and cheap hardware often used hit-and-miss components, as on the notorious Commodore 64 disc controller. If somebody experienced an apparent bug in play, it could easily be that he had a corrupt disc or was unable to read data of that density. So the VERIFY command, which took up to ten minutes on some early computers, would chug through the entire story file and compute a checksum, compare it against a known result in the header, and determine that the story file could or could not properly be read. The Z-machine provided this service as an opcode, and so Glulx followed suit.

```
[ VERIFY_THE_STORY_FILE_R;
    if (actor ~= player) rfalse;
    @verify ?Vmaybe;
    jump Vwrong;
    .Vmaybe; return GL__M(##Verify,1);
    .Vwrong;
    GL__M(##Verify,2);
];
```

§27. Switch Transcript On Rule.

```
[ SWITCH_TRANSCRIPT_ON_R;
    if (actor ~= player) rfalse;
    transcript_mode = ((0-->8) & 1);
    if (transcript_mode) return GL__M(##ScriptOn,1);
    @output_stream 2;
    if (((0-->8) & 1) == 0) return GL__M(##ScriptOn,3);
    GL__M(##ScriptOn,2); VersionSub();
    transcript_mode = true;
];
```

§28. Switch Transcript Off Rule.

```
[ SWITCH_TRANSCRIPT_OFF_R;
    if (actor ~= player) rfalse;
    transcript_mode = ((0-->8) & 1);
    if (transcript_mode == false) return GL__M(##ScriptOff,1);
    GL__M(##ScriptOff,2);
    @output_stream -2;
    if ((0-->8) & 1) return GL__M(##ScriptOff,3);
    transcript_mode = false;
];
```

§29. Announce Story File Version Rule.

```
[ ANNOUNCE_STORY_FILE_VERSION_R ix;
    if (actor ~= player) rfalse;
    Banner();
    print "Identification number: ";
    for (ix=6: ix <= UUID_ARRAY->0: ix++) print (char) UUID_ARRAY->ix;
    print "^";
    ix = 0; ! shut up compiler warning
    if (standard_interpreter > 0) {
        print "Standard interpreter ",
            standard_interpreter/256, ".", standard_interpreter%256,
            " (", HDR_TERPNUMBER->0;
        #Iftrue (#version_number == 6);
        print (char) '.', HDR_TERPVERSION->0;
        #Ifnot;
        print (char) HDR_TERPVERSION->0;
        #Endif;
        print ") / ";
    } else {
        print "Interpreter ", HDR_TERPNUMBER->0, " Version ";
        #Iftrue (#version_number == 6);
        print HDR_TERPVERSION->0;
        #Ifnot;
        print (char) HDR_TERPVERSION->0;
        #Endif;
        print " / ";
    }
    print "Library serial number ", (string) LibSerial, "^";
    #Ifdef LanguageVersion;
    print (string) LanguageVersion, "^";
    #Endif; ! LanguageVersion
    #ifdef ShowExtensionVersions;
    ShowExtensionVersions();
    #endif;
    say__p = 1;
];
```

§**30. Descend To Specific Action Rule.** There are 100 or so actions, typically, and this rule is for efficiency's sake: rather than perform 100 or so comparisons to see which routine to call, we indirect through a jump table. The routines called are the `-Sub` routines: thus, for instance, if `action` is `##Wait` then `WaitSub` is called. It is essential that this routine not be called for fake actions: in I7 use this is guaranteed, since fake actions are not allowed into the action machinery at all.

Strangely, Glulx's action routines table is numbered in an off-by-one way compared to the Z-machine's: hence the `+1`.

```
[ DESCEND_TO_SPECIFIC_ACTION_R;
    indirect(#actions_table-->action);
    rtrue;
];
```

§**31. Veneer.**

```

```

Purpose

To start up the Glk interface for the Glulx virtual machine, and provide Glulx-specific printing functions.

§**1. Summary.** This segment closely parallels "ZMachine.i6t", which provides exactly equivalent functionality (indeed, usually the same-named functions and in the same order) for the Z-machine VM. This is intended to make the rest of the template code independent of the choice of VM, although that is more of an ideal than a reality, because there are so many fiddly differences in some of the grammar and dictionary tables that it is not really practical for the parser (for instance) to call VM-neutral routines to get the data it wants out of these arrays.

§2. Variables and Arrays.

```
Array gg_event --> 4;
Array gg_arguments buffer 28;
Global gg_mainwin = 0;
Global gg_statuswin = 0;
Global gg_quotewin = 0;
Global gg_scriptfref = 0;
Global gg_scriptstr = 0;
Global gg_savestr = 0;
Global gg_commandstr = 0;
Global gg_command_reading = 0;      ! true if gg_commandstr is being replayed
Global gg_foregroundchan = 0;
Global gg_backgroundchan = 0;

Constant INPUT_BUFFER_LEN = 260;    ! No extra byte necessary
Constant MAX_BUFFER_WORDS = 20;
Constant PARSE_BUFFER_LEN = 61;

Array  buffer    buffer INPUT_BUFFER_LEN;
Array  buffer2   buffer INPUT_BUFFER_LEN;
Array  buffer3   buffer INPUT_BUFFER_LEN;
Array  parse     --> PARSE_BUFFER_LEN;
Array  parse2    --> PARSE_BUFFER_LEN;
```

§**3. Infglk.** This section is a verbatim copy of John Cater's invaluable I6 header file `infglk.h`, kindly donated by the author. The routines are convenient to have on hand, and also provide a canonical set of I6 names for the many gestalt and other codes.

§**4. Rocks.** These are unique ID codes used to mark resources; think of them as inedible cookies.

```
Constant GG_MAINWIN_ROCK        201;
Constant GG_STATUSWIN_ROCK      202;
Constant GG_QUOTEWIN_ROCK       203;
Constant GG_SAVESTR_ROCK        301;
Constant GG_SCRIPTSTR_ROCK      302;
Constant GG_COMMANDWSTR_ROCK    303;
Constant GG_COMMANDRSTR_ROCK    304;
Constant GG_SCRIPTFREF_ROCK     401;
Constant GG_FOREGROUNDCHAN_ROCK 410;
Constant GG_BACKGROUNDCHAN_ROCK 411;
```

§**5. Stubs.** These are I6 library-style entry point routines, not used by I7, but retained in case I7 extensions want to do interesting things with Glulx.

```
#Stub HandleGlkEvent    2;
#Stub IdentifyGlkObject 4;
#Stub InitGlkWindow     1;
```

§**6. Starting Up.** `VM_Initialise()` is almost the first routine called, except that the "starting the virtual machine" activity is allowed to go first.

Arrangements are a little different here from on the Z-machine, because some data is retained in the case of a restart.

(Many thanks are due to Eliuk Blau, who found several tricky timing errors here and elsewhere in the Glulx-specific code. Frankly, I feel like hanging a sign on the following routines which reads "Congratulations on bringing light to the Dark Room.")

```
[ VM_Initialise res sty;
    @gestalt 4 2 res; ! Test if this interpreter has Glk...
    if (res == 0) quit; ! ...without which there would be nothing we could do

    unicode_gestalt_ok = false;
    if (glk_gestalt(gestalt_Unicode, 0))
        unicode_gestalt_ok = true;

    ! Set the VM's I/O system to be Glk.
    @setiosys 2 0;

    ! First, we must go through all the Glk objects that exist, and see
    ! if we created any of them. One might think this strange, since the
    ! program has just started running, but remember that the player might
    ! have just typed "restart".

    GGRecoverObjects();

    ! Sound channel initialisation, and RNG fixing, must be done now rather
    ! than later in case InitGlkWindow() returns a non-zero value.

    if (glk_gestalt(gestalt_Sound, 0)) {
        if (gg_foregroundchan == 0)
            gg_foregroundchan = glk_schannel_create(GG_FOREGROUNDCHAN_ROCK);
        if (gg_backgroundchan == 0)
            gg_backgroundchan = glk_schannel_create(GG_BACKGROUNDCHAN_ROCK);
    }

    #ifdef FIX_RNG;
    @random 10000 i;
    i = -i-2000;
    print "[Random number generator seed is ", i, "]^";
    @setrandom i;
    #endif; ! FIX_RNG

    res = InitGlkWindow(0);
    if (res ~= 0) return;

    ! Now, gg_mainwin and gg_storywin might already be set. If not, set them.

    if (gg_mainwin == 0) {
        ! Open the story window.
        res = InitGlkWindow(GG_MAINWIN_ROCK);
        if (res == 0) {

```

§**8. Release Number.** Like all software, IF story files have release numbers to mark revised versions being circulated: unlike most software, and partly for traditional reasons, the version number is recorded not in some print statement or variable but is branded on, so to speak, in a specific memory location of the story file header.

`VM_Describe_Release()` describes the release and is used as part of the "banner", IF's equivalent to a title page.

```
[ VM_Describe_Release i;
    print "Release ";
    @aloads ROM_GAMERELEASE 0 i;
    print i;
    print " / Serial number ";
    for (i=0 : i<6 : i++) print (char) ROM_GAMESERIAL->i;
];
```

§**9. Keyboard Input.** The VM must provide three routines for keyboard input:

(a) `VM_KeyChar()` waits for a key to be pressed and then returns the character chosen as a ZSCII character.
(b) `VM_KeyDelay(N)` waits up to $N/10$ seconds for a key to be pressed, returning the ZSCII character if so, or 0 if not.
(c) `VM_ReadKeyboard(b, t)` reads a whole newline-terminated command into the buffer `b`, then parses it into a word stream in the table `t`.

There are elaborations to due with mouse clicks, but this isn't the place to document all of that.

```

§**10. Buffer Functions.** A "buffer", in this sense, is an array containing a stream of characters typed from the keyboard; a "parse buffer" is an array which resolves this into individual words, pointing to the relevant entries in the dictionary structure. Because each VM has its own format for each of these arrays (not to mention the dictionary), we have to provide some standard operations needed by the rest of the template as routines for each VM.

`VM_CopyBuffer(to, from)` copies one buffer into another.

`VM_Tokenise(buff, parse_buff)` takes the text in the buffer `buff` and produces the corresponding data in the parse buffer `parse_buff` – this is called tokenisation since the characters are divided into words: in traditional computing jargon, such clumps of characters treated syntactically as units are called tokens.

`LTI_Insert` is documented in the DM4 and the `LTI` prefix stands for "Language To Informese": it's used only by translations into non-English languages of play, and is not called in the template.

```
[ VM_CopyBuffer bto bfrom i;
    for (i=0: i<INPUT_BUFFER_LEN: i++) bto->i = bfrom->i;
];
[ VM_PrintToBuffer buf len a b c;
    if (b) {
        if (metaclass(a) == Object && a.#b == WORDSIZE
            && metaclass(a.b) == String)
            buf-->0 = Glulx_PrintAnyToArray(buf+WORDSIZE, len, a.b);
        else if (metaclass(a) == Routine)
            buf-->0 = Glulx_PrintAnyToArray(buf+WORDSIZE, len, a, b, c);
        else
            buf-->0 = Glulx_PrintAnyToArray(buf+WORDSIZE, len, a, b);
    }
    else if (metaclass(a) == Routine)
        buf-->0 = Glulx_PrintAnyToArray(buf+WORDSIZE, len, a, b, c);
    else
        buf-->0 = Glulx_PrintAnyToArray(buf+WORDSIZE, len, a);
    if (buf-->0 > len) buf-->0 = len;
    return buf-->0;
];
[ VM_Tokenise buf tab
    cx numwords len bx ix wx wpos wlen val res dictlen entrylen;
    len = buf-->0;
    buf = buf+WORDSIZE;
    ! First, split the buffer up into words. We use the standard Infocom
    ! list of word separators (comma, period, double-quote).
    cx = 0;
    numwords = 0;
    while (cx < len) {
        while (cx < len && buf->cx == ' ') cx++;
        if (cx >= len) break;
        bx = cx;
```

```
        if (buf->cx == '.' or ',' or '"') cx++;
        else {
            while (cx < len && buf->cx ~= ' ' or '.' or ',' or '"') cx++;
        }
        tab-->(numwords*3+2) = (cx-bx);
        tab-->(numwords*3+3) = WORDSIZE+bx;
        numwords++;
        if (numwords >= MAX_BUFFER_WORDS) break;
    }
    tab-->0 = numwords;

    ! Now we look each word up in the dictionary.

    dictlen = #dictionary_table-->0;
    entrylen = DICT_WORD_SIZE + 7;

    for (wx=0 : wx<numwords : wx++) {
        wlen = tab-->(wx*3+2);
        wpos = tab-->(wx*3+3);

        ! Copy the word into the gg_tokenbuf array, clipping to DICT_WORD_SIZE
        ! characters and lower case.
        if (wlen > DICT_WORD_SIZE) wlen = DICT_WORD_SIZE;
        cx = wpos - WORDSIZE;
        for (ix=0 : ix<wlen : ix++) gg_tokenbuf->ix = VM_UpperToLowerCase(buf->(cx+ix));
        for (: ix<DICT_WORD_SIZE : ix++) gg_tokenbuf->ix = 0;

        val = #dictionary_table + WORDSIZE;
        @binarysearch gg_tokenbuf DICT_WORD_SIZE val entrylen dictlen 1 1 res;
        tab-->(wx*3+1) = res;
    }
];

[ LTI_Insert i ch  b y;

    ! Protect us from strict mode, as this isn't an array in quite the
    ! sense it expects
    b = buffer;

    ! Insert character ch into buffer at point i.
    ! Being careful not to let the buffer possibly overflow:
    y = b-->0;
    if (y > INPUT_BUFFER_LEN) y = INPUT_BUFFER_LEN;

    ! Move the subsequent text along one character:
    for (y=y+WORDSIZE : y>i : y--) b->y = b->(y-1);
    b->i = ch;

    ! And the text is now one character longer:
    if (b-->0 < INPUT_BUFFER_LEN) (b-->0)++;
];
```

§**11. Dictionary Functions.** Again, the dictionary structure is differently arranged on the different VMs. This is a data structure containing, in compressed form, the text of all the words to be recognised by tokenisation (above). In I6 for Glulx, a dictionary word is represented at run-time by its record's address in the dictionary.

`VM_InvalidDictionaryAddress(A)` tests whether `A` is a valid record address in the dictionary data structure. In Glulx, dictionary records might in theory be anywhere in the 2 GB or so of possible memory, but we can rule out negative addresses. (This allows −1, say, to be used as a value meaning "not a valid dictionary word".)

`VM_DictionaryAddressToNumber(A)` and `VM_NumberToDictionaryAddress(N)` convert between word addresses and their run-time representations: since, on Glulx, they are the same, these are each the identity function.

```
[ VM_InvalidDictionaryAddress addr;
    if (addr < 0) rtrue;
    rfalse;
];
[ VM_DictionaryAddressToNumber w; return w; ];
[ VM_NumberToDictionaryAddress n; return n; ];
Array gg_tokenbuf -> DICT_WORD_SIZE;
[ GGWordCompare str1 str2 ix jx;
    for (ix=0 : ix<DICT_WORD_SIZE : ix++) {
        jx = (str1->ix) - (str2->ix);
        if (jx ~= 0) return jx;
    }
    return 0;
];
```

§**12. SHOWVERB support.** Further VM-specific tables cover actions and attributes, and these are used by the SHOWVERB testing command.

```
#Ifdef DEBUG;
[ DebugAction a str;
    if (a >= 4096) { print "<fake action ", a-4096, ">"; return; }
    if (a < 0 || a >= #identifiers_table-->7) print "<invalid action ", a, ">";
    else {
        str = #identifiers_table-->6;
        str = str-->a;
        if (str) print (string) str; else print "<unnamed action ", a, ">";
    }
];
[ DebugAttribute a str;
    if (a < 0 || a >= NUM_ATTR_BYTES*8) print "<invalid attribute ", a, ">";
    else {
        str = #identifiers_table-->4;
        str = str-->a;
        if (str) print (string) str; else print "<unnamed attribute ", a, ">";
    }
];
#Endif;
```

§**13. Command Tables.** The VM is also generated containing a data structure for the grammar produced by I6's `Verb` and `Extend` directives: this is essentially a list of command verbs such as DROP or PUSH, together with a list of synonyms, and then the grammar for the subsequent commands to be recognised by the parser.

```
[ VM_CommandTableAddress i;
    return (#grammar_table)-->(i+1);
];
[ VM_PrintCommandWords i wd j dictlen entrylen;
    dictlen = #dictionary_table-->0;
    entrylen = DICT_WORD_SIZE + 7;
    for (j=0 : j<dictlen : j++) {
        wd = #dictionary_table + WORDSIZE + entrylen*j;
        if (DictionaryWordToVerbNum(wd) == i)
            print "'", (address) wd, "' ";
    }
];
```

§**14. Random Number Generator.** No routine is needed for extracting a random number, since I6's built-in `random` function does that, but it's useful to abstract the process of seeding the RNG so that it produces a repeatable sequence of "random" numbers from here on: the necessary opcodes are different for the two VMs.

```
[ VM_Seed_RNG n;
    @setrandom n;
];
```

§**15. Memory Allocation.** This is dynamic memory allocation: something which is never practicable in the Z-machine, because the whole address range is already claimed, but which is viable on recent revisions of Glulx.

```
[ VM_AllocateMemory amount i;
    @gestalt 7 0 i;
    if (i == 0) return i;
    @malloc amount i;
    return i;
];
[ VM_FreeMemory address i;
    @gestalt 7 0 i;
    if (i == 0) return;
    @mfree address;
];
```

§**16. Audiovisual Resources.** The Z-machine only barely supports figures and sound effects, so Glulx is the preferred VM to choose if they are wanted. Properly speaking, it's not Glulx which supports these, but its I/O layer Glk, and implementations of Glk are free to support them or not as they please: "cheapglk", a dumb terminal version, does not, for instance. We therefore have to investigate the "gestalt" to find out.

```
[ VM_Picture resource_ID;
    if (glk_gestalt(gestalt_Graphics, 0)) {
        glk_image_draw(gg_mainwin, resource_ID, imagealign_InlineCenter, 0);
    } else {
        print "[Picture number ", resource_ID, " here.]^";
    }
];
[ VM_SoundEffect resource_ID;
    if (glk_gestalt(gestalt_Sound, 0)) {
        glk_schannel_play(gg_foregroundchan, resource_ID);
    } else {
        print "[Sound effect number ", resource_ID, " here.]^";
    }
];
```

§**17. Typography.** Glk makes an attempt to present typographic styles as being a matter of semantic markup rather than controlling the actual appearance of text: the idea is that the story file should want to print something in a heading kind of way, and then the interpreter – guided by the player's reading preferences – might set that in bold, or larger type, or red ink, or any combination of the three, or with other effects entirely. This is not the place to discuss whether that was a wise decision for Glk to take (it really, really, *really* wasn't): we can only play along.

```
[ VM_Style sty;
    switch (sty) {
        NORMAL_VMSTY:     glk_set_style(style_Normal);
        HEADER_VMSTY:     glk_set_style(style_Header);
        SUBHEADER_VMSTY:  glk_set_style(style_Subheader);
        NOTE_VMSTY:       glk_set_style(style_Note);
        ALERT_VMSTY:      glk_set_style(style_Alert);
        BLOCKQUOTE_VMSTY: glk_set_style(style_BlockQuote);
        INPUT_VMSTY:      glk_set_style(style_Input);
    }
];
```

§**18. Character Casing.** The following are the equivalent of `tolower` and `toupper`, the traditional C library functions for forcing letters into lower and upper case form, for the ZSCII character set. Note that Glulx can also use Unicode characters for some purposes (Unicode was a relatively late addition to the Glulx standard), and we make good use of this when storing indexed text.

```
[ VM_UpperToLowerCase c; return glk_char_to_lower(c); ];
[ VM_LowerToUpperCase c; return glk_char_to_upper(c); ];
```

§**19. Glulx-Only Printing Routines.** Partly because of the smallness of the range of representable values in the Z-machine, there is little run-time type-checking that can be done: for instance a dictionary address cannot be distinguished from a function address because they are encoded differently, so that a function address (which is packed) could well coincide with that of a dictionary word (which is not). On Glulx these restrictions are somewhat lifted, so that it's possible to write a routine which can look at a value, work out what it must mean, and print it suitably. This is only possible up to a point – for instance, it can't distinguish an integer from a function address – and in I7 the use of this sort of trick is much less important because type-checking in the NI compiler handles the problem much better. Still, we retain some Glulx-only features because they are convenient for writing external files to disc, for instance, something which the Z-machine can't do in any case.

`Glulx_PrintAnything` handles strings, functions (with optional arguments), objects, object properties (with optional arguments), and dictionary words.

`Glulx_PrintAnyToArray` does the same, but the output is sent to a byte array in memory. The first two arguments must be the array address and length; subsequent arguments are as for `Glulx_PrintAnything`. The return value is the number of characters output. If the output is longer than the array length given, the extra characters are discarded, so the array does not overflow. (However, the return value is the total length of the output, including discarded characters.) The character set stored here is ZSCII, not Unicode.

`Glulx_ChangeAnyToCString` calls `Glulx_PrintAnyToArray` on a particular array, then amends the result to make it a C-style string – that is, a sequence of byte-sized characters which are null terminated. The character set stored here is once again ZSCII, not Unicode.

```
! Glulx_PrintAnything()                    <nothing printed>
! Glulx_PrintAnything(0)                   <nothing printed>
! Glulx_PrintAnything("string");           print (string) "string";
! Glulx_PrintAnything('word')              print (address) 'word';
! Glulx_PrintAnything(obj)                 print (name) obj;
! Glulx_PrintAnything(obj, prop)           obj.prop();
! Glulx_PrintAnything(obj, prop, args...)  obj.prop(args...);
! Glulx_PrintAnything(func)                func();
! Glulx_PrintAnything(func, args...)       func(args...);
[ Glulx_PrintAnything _vararg_count obj mclass;
    if (_vararg_count == 0) return;
    @copy sp obj;
    _vararg_count--;
    if (obj == 0) return;
    if (obj->0 == $60) {
        ! Dictionary word. Metaclass() can't catch this case, so we do it manually
        print (address) obj;
        return;
    }
    mclass = metaclass(obj);
    switch (mclass) {
    nothing:
        return;
    String:
        print (string) obj;
        return;
    Routine:

§**20. The Screen.** Our generic screen model is that the screen is made up of windows: we tend to refer only to two of these, the main window and the status line, but others may also exist from time to time. Windows have unique ID numbers: the special window ID −1 means "all windows" or "the entire screen", which usually amounts to the same thing.

Screen height and width are measured in characters, with respect to the fixed-pitch font used for the status line. The main window normally contains variable-pitch text which may even have been kerned, and character dimensions make little sense there.

```
[ VM_ClearScreen window;
    if (window == WIN_ALL or WIN_MAIN) {
        glk_window_clear(gg_mainwin);
        if (gg_quotewin) {
            glk_window_close(gg_quotewin, 0);
            gg_quotewin = 0;
        }
    }
    if (gg_statuswin && window == WIN_ALL or WIN_STATUS) glk_window_clear(gg_statuswin);
];
[ VM_ScreenWidth  id;
    id=gg_mainwin;
    if (gg_statuswin && statuswin_current) id = gg_statuswin;
    glk_window_get_size(id, gg_arguments, 0);
    return gg_arguments-->0;
];
[ VM_ScreenHeight;
    glk_window_get_size(gg_mainwin, 0, gg_arguments);
    return gg_arguments-->0;
];
```

§**21. Window Colours.** Our generic screen model is that the screen is made up of windows, each of which can have its own foreground and background colours.

The colour of individual letters or words of type is not controllable in Glulx, to the frustration of many, and so the template layer of I7 has no framework for handling this (even though it is controllable on the Z-machine, which is greatly superior in this respect).

```
[ VM_SetWindowColours f b window doclear  i fwd bwd swin;
    if (clr_on && f && b) {
        if (window) swin = 5-window; ! 4 for TextGrid, 3 for TextBuffer
        fwd = MakeColourWord(f);
        bwd = MakeColourWord(b);
        for (i=0 : i<style_NUMSTYLES: i++) {
            if (f == CLR_DEFAULT || b == CLR_DEFAULT) {  ! remove style hints
                glk_stylehint_clear(swin, i, stylehint_TextColor);
                glk_stylehint_clear(swin, i, stylehint_BackColor);
            } else {
                glk_stylehint_set(swin, i, stylehint_TextColor, fwd);
                glk_stylehint_set(swin, i, stylehint_BackColor, bwd);
            }
        }
        ! Now re-open the windows to apply the hints
        if (gg_statuswin) glk_window_close(gg_statuswin, 0);
```

```
        gg_statuswin = 0;
        if (doclear || ( window ~= 1 && (clr_fg ~= f || clr_bg ~= b) ) ) {
            glk_window_close(gg_mainwin, 0);
            gg_mainwin = glk_window_open(0, 0, 0, wintype_TextBuffer, GG_MAINWIN_ROCK);
            if (gg_scriptstr ~= 0)
                glk_window_set_echo_stream(gg_mainwin, gg_scriptstr);
        }
        gg_statuswin =
            glk_window_open(gg_mainwin, winmethod_Fixed + winmethod_Above,
                statuswin_cursize, wintype_TextGrid, GG_STATUSWIN_ROCK);
        if (statuswin_current && gg_statuswin) VM_MoveCursorInStatusLine(); else VM_MainWindow();
        if (window ~= 2) {
            clr_fgstatus = f;
            clr_bgstatus = b;
        }
        if (window ~= 1) {
            clr_fg = f;
            clr_bg = b;
        }
    }
];
[ VM_RestoreWindowColours; ! used after UNDO: compare I6 patch L61007
    if (clr_on) { ! check colour has been used
        VM_SetWindowColours(clr_fg, clr_bg, 2); ! make sure both sets of variables are restored
        VM_SetWindowColours(clr_fgstatus, clr_bgstatus, 1, true);
        VM_ClearScreen();
    }
];
[ MakeColourWord c;
    if (c > 9) return c;
    c = c-2;
    return $ff0000*(c&1) + $ff00*(c&2 ~= 0) + $ff*(c&4 ~= 0);
];
```

§**22. Main Window.** The part of the screen on which commands and responses are printed, which ordinarily occupies almost all of the screen area.

`VM_MainWindow()` switches printing back from another window, usually the status line, to the main window.

```
[ VM_MainWindow;
    glk_set_window(gg_mainwin); ! set_window
    statuswin_current=0;
];
```

§**23. Status Line.** Despite the name, the status line need not be a single line at the top of the screen: that's only the conventional default arrangement. It can expand to become the equivalent of an old-fashioned VT220 terminal, with menus and grids and mazes displayed lovingly in character graphics, or it can close up to invisibility.

`VM_StatusLineHeight(n)` sets the status line to have a height of `n` lines of type. (The width of the status line is always the width of the whole screen, and the position is always at the top, so the height is the only controllable aspect.) The $n = 0$ case makes the status line disappear.

`VM_MoveCursorInStatusLine(x, y)` switches printing to the status line, positioning the "cursor" – the position at which printing will begin – at the given character grid position (x, y). Line 1 represents the top line; line 2 is underneath, and so on; columns are similarly numbered from 1 at the left.

```
[ VM_StatusLineHeight hgt;
    if (gg_statuswin == 0) return;
    if (hgt == statuswin_cursize) return;
    glk_window_set_arrangement(glk_window_get_parent(gg_statuswin), $12, hgt, 0);
    statuswin_cursize = hgt;
];
[ VM_MoveCursorInStatusLine line column;
    if (gg_statuswin == 0) return;
    glk_set_window(gg_statuswin);
    if (line == 0) { line = 1; column = 1; }
    glk_window_move_cursor(gg_statuswin, column-1, line-1);
    statuswin_current=1;
];
```

§**24. Quotation Boxes.** On the Z-machine, quotation boxes are produced by stretching the status line, but on Glulx they usually occupy windows of their own. If it isn't possible to create such a window, so that `gg_quotewin` is zero below, the quotation text just appears in the main window.

```
[ Box__Routine maxwid arr ix lines lastnl parwin;
    maxwid = 0; ! squash compiler warning
    lines = arr-->0;
    if (gg_quotewin == 0) {
        gg_arguments-->0 = lines;
        ix = InitGlkWindow(GG_QUOTEWIN_ROCK);
        if (ix == 0)
            gg_quotewin =
                glk_window_open(gg_mainwin, winmethod_Fixed + winmethod_Above,
                    lines, wintype_TextBuffer, GG_QUOTEWIN_ROCK);
    } else {
        parwin = glk_window_get_parent(gg_quotewin);
        glk_window_set_arrangement(parwin, $12, lines, 0);
    }
    lastnl = true;
    if (gg_quotewin) {
        glk_window_clear(gg_quotewin);
        glk_set_window(gg_quotewin);
        lastnl = false;
    }
    VM_Style(BLOCKQUOTE_VMSTY);
    for (ix=0 : ix<lines : ix++) {
```

```
        print (string) arr-->(ix+1);
        if (ix < lines-1 || lastnl) new_line;
    }
    VM_Style(NORMAL_VMSTY);
    if (gg_quotewin) glk_set_window(gg_mainwin);
];
```

§**25. GlkList Command.** GLKLIST is a testing command best used by those who understand Glulx and its ways: it isn't documented in the I7 manual, because it is pretty inscrutable for "real" users, but it's probably worth keeping just the same.

```
#Ifdef DEBUG;
[ GlkListSub id val;
    id = glk_window_iterate(0, gg_arguments);
    while (id) {
        print "Window ", id, " (", gg_arguments-->0, "): ";
        val = glk_window_get_type(id);
        switch (val) {
        1: print "pair";
        2: print "blank";
        3: print "textbuffer";
        4: print "textgrid";
        5: print "graphics";
        default: print "unknown";
        }
        val = glk_window_get_parent(id);
        if (val) print ", parent is window ", val;
        else     print ", no parent (root)";
        val = glk_window_get_stream(id);
        print ", stream ", val;
        val = glk_window_get_echo_stream(id);
        if (val) print ", echo stream ", val;
        print "^";
        id = glk_window_iterate(id, gg_arguments);
    }
    id = glk_stream_iterate(0, gg_arguments);
    while (id) {
        print "Stream ", id, " (", gg_arguments-->0, ")^";
        id = glk_stream_iterate(id, gg_arguments);
    }
    id = glk_fileref_iterate(0, gg_arguments);
    while (id) {
        print "Fileref ", id, " (", gg_arguments-->0, ")^";
        id = glk_fileref_iterate(id, gg_arguments);
    }
    if (glk_gestalt(gestalt_Sound, 0)) {
        id = glk_schannel_iterate(0, gg_arguments);
        while (id) {
            print "Soundchannel ", id, " (", gg_arguments-->0, ")^";
            id = glk_schannel_iterate(id, gg_arguments);
        }
    }
```

```
];
{-testing-command:glklist}
    *                                           -> Glklist;
#Endif;
```

§**26. Undo.** These are really emulations of the Z-machine's conventions on UNDO: Glulx's undo opcodes used different result codes while providing essentially the same functionality, for reasons which are opaque, but no trouble is caused thereby.

```
[ VM_Undo result_code;
    @restoreundo result_code;
    return (~~result_code);
];
[ VM_Save_Undo result_code;
    @saveundo result_code;
    if (result_code == -1) { GGRecoverObjects(); return 2; }
    return (~~result_code);
];
```

§27. Quit The Game Rule.

```
[ QUIT_THE_GAME_R;
    if (actor ~= player) rfalse;
    GL__M(##Quit, 2); if (YesOrNo()~=0) quit;
];
```

§28. Restart The Game Rule.

```
[ RESTART_THE_GAME_R;
    if (actor ~= player) rfalse;
    GL__M(##Restart, 1);
    if (YesOrNo() ~= 0) {
        @restart;
        GL__M(##Restart, 2);
    }
];
```

§29. Restore The Game Rule.

```
[ RESTORE_THE_GAME_R res fref;
    if (actor ~= player) rfalse;
    fref = glk_fileref_create_by_prompt($01, $02, 0);
    if (fref == 0) jump RFailed;
    gg_savestr = glk_stream_open_file(fref, $02, GG_SAVESTR_ROCK);
    glk_fileref_destroy(fref);
    if (gg_savestr == 0) jump RFailed;
    @restore gg_savestr res;
    glk_stream_close(gg_savestr, 0);
    gg_savestr = 0;
    .RFailed;
    GL__M(##Restore, 1);
];
```

§30. Save The Game Rule.

```
[ SAVE_THE_GAME_R res fref;
    if (actor ~= player) rfalse;
    fref = glk_fileref_create_by_prompt($01, $01, 0);
    if (fref == 0) jump SFailed;
    gg_savestr = glk_stream_open_file(fref, $01, GG_SAVESTR_ROCK);
    glk_fileref_destroy(fref);
    if (gg_savestr == 0) jump SFailed;
    @save gg_savestr res;
    if (res == -1) {
        ! The player actually just typed "restore". We're going to print
        !  GL__M(##Restore,2); the Z-Code Inform library does this correctly
        ! now. But first, we have to recover all the Glk objects; the values
        ! in our global variables are all wrong.
        GGRecoverObjects();
        glk_stream_close(gg_savestr, 0); ! stream_close
        gg_savestr = 0;
        return GL__M(##Restore, 2);
    }
    glk_stream_close(gg_savestr, 0); ! stream_close
    gg_savestr = 0;
    if (res == 0) return GL__M(##Save, 2);
    .SFailed;
    GL__M(##Save, 1);
];
```

§31. Verify The Story File Rule. This is a fossil now, really, but in the days of Infocom, the 110K story file occupying an entire disc was a huge data set: floppy discs were by no means a reliable medium, and cheap hardware often used hit-and-miss components, as on the notorious Commodore 64 disc controller. If somebody experienced an apparent bug in play, it could easily be that he had a corrupt disc or was unable to read data of that density. So the VERIFY command, which took up to ten minutes on some early computers, would chug through the entire story file and compute a checksum, compare it against a known result in the header, and determine that the story file could or could not properly be read. The Z-machine provided this service as an opcode, and so Glulx followed suit.

```
[ VERIFY_THE_STORY_FILE_R res;
    if (actor ~= player) rfalse;
    @verify res;
    if (res == 0) return GL__M(##Verify, 1);
    GL__M(##Verify, 2);
];
```

§32. Switch Transcript On Rule.

```
[ SWITCH_TRANSCRIPT_ON_R;
    if (actor ~= player) rfalse;
    if (gg_scriptstr ~= 0) return GL__M(##ScriptOn, 1);
    if (gg_scriptfref == 0) {
        gg_scriptfref = glk_fileref_create_by_prompt($102, $05, GG_SCRIPTFREF_ROCK);
        if (gg_scriptfref == 0) jump S1Failed;
    }
    ! stream_open_file
    gg_scriptstr = glk_stream_open_file(gg_scriptfref, $05, GG_SCRIPTSTR_ROCK);
    if (gg_scriptstr == 0) jump S1Failed;
    glk_window_set_echo_stream(gg_mainwin, gg_scriptstr);
    GL__M(##ScriptOn, 2);
    VersionSub();
    return;
    .S1Failed;
    GL__M(##ScriptOn, 3);
];
```

§33. Switch Transcript Off Rule.

```
[ SWITCH_TRANSCRIPT_OFF_R;
    if (actor ~= player) rfalse;
    if (gg_scriptstr == 0) return GL__M(##ScriptOff,1);
    GL__M(##ScriptOff, 2);
    glk_stream_close(gg_scriptstr, 0); ! stream_close
    gg_scriptstr = 0;
];
```

§34. Announce Story File Version Rule.

```
[ ANNOUNCE_STORY_FILE_VERSION_R ix;
    if (actor ~= player) rfalse;
    Banner();
    print "Identification number: ";
    for (ix=6: ix <= UUID_ARRAY->0: ix++) print (char) UUID_ARRAY->ix;
    print "^";
    @gestalt 1 0 ix;
    print "Interpreter version ", ix / $10000, ".", (ix & $FF00) / $100,
    ".", ix & $FF, " / ";
    @gestalt 0 0 ix;
    print "VM ", ix / $10000, ".", (ix & $FF00) / $100, ".", ix & $FF, " / ";
    print "Library serial number ", (string) LibSerial, "^";
    #Ifdef LanguageVersion;
    print (string) LanguageVersion, "^";
    #Endif; ! LanguageVersion
    ShowExtensionVersions();
    say__p = 1;
];
```

§**35. Descend To Specific Action Rule.** There are 100 or so actions, typically, and this rule is for efficiency's sake: rather than perform 100 or so comparisons to see which routine to call, we indirect through a jump table. The routines called are the `-Sub` routines: thus, for instance, if `action` is `##Wait` then `WaitSub` is called. It is essential that this routine not be called for fake actions: in I7 use this is guaranteed, since fake actions are not allowed into the action machinery at all.

Strangely, Glulx's action routines table is numbered in an off-by-one way compared to the Z-machine's: hence the `+1`.

```
[ DESCEND_TO_SPECIFIC_ACTION_R;
    indirect(#actions_table-->(action+1));
    rtrue;
];
```

FileIO Template B/iot

Purpose

Reading and writing external files, in the Glulx virtual machine only.

---

§**1. Structure.** The I7 kind of value "auxiliary-file" is an `-->` array, holding a memory structure containing information about external files. The following constants specify memory offsets and values. Note the safety value stored as the first word of the structure: this helps protect the routines below from accidents. (16339, besides being prime, is a number interesting to the author of Inform since it was the examination board identifying number of his school, and so had to be filled in on all of the many papers he sat during his formative years.)

```
Constant AUXF_MAGIC = 0; ! First word holds a safety constant
Constant AUXF_MAGIC_VALUE = 16339; ! Should be first word of any valid file structure
Constant AUXF_STATUS = 1; ! One of the following:
    Constant AUXF_STATUS_IS_UNUSED = 0; ! Never used
    Constant AUXF_STATUS_IS_CLOSED = 1; ! Currently closed
    Constant AUXF_STATUS_IS_OPEN_FOR_READ = 2;
    Constant AUXF_STATUS_IS_OPEN_FOR_WRITE = 3;
    Constant AUXF_STATUS_IS_OPEN_FOR_APPEND = 4;
Constant AUXF_BINARY = 2; ! False for text files (I7 default), true for binary
Constant AUXF_FREF = 3; ! Glulx file reference number (if file has been used)
Constant AUXF_STREAM = 4; ! Stream for an open file (meaningless otherwise)
Constant AUXF_FILENAME = 5; ! Packed address of constant string
Constant AUXF_IFID_OF_OWNER = 6; ! UUID_ARRAY if owned by this project, or
    ! string array of IFID of owner wrapped in //...//, or NULL to leave open
```

§**2. Instances.** These structures are not dynamically created: they are precompiled by the NI compiler, already filled in with the necessary values. The following command generates them.

```
{-call:external_file_arrays}
```

§**3. Errors.** This is used for I/O errors of all kinds: it isn't within the Glulx-only code because one of the errors is to try to use these routines on the Z-machine.

```
[ FileIO_Error auxf err_text;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE)) {
        print "^*** Error on unknown file: ", (string) err_text, " ***^";
    } else
        print "^*** Error on file '", (string) auxf-->AUXF_FILENAME, "': ",
            (string) err_text, " ***^";
    RunTimeProblem(RTP_FILEIOERROR);
    return 0;
];
```

§**4. Glulx Material.**

```
#IFDEF TARGET_GLULX;
```

§**5. Obtain File Reference.** Obtain the file reference for a file (which need not exist). `auxf` is the memory location of the auxiliary file structure; a file reference is a Glulx concept.

```
[ FileIO_Fref auxf  fref usage;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE)) rfalse;
    if (auxf-->AUXF_STATUS == 0) {
        if (auxf-->AUXF_BINARY) usage = fileusage_BinaryMode;
        else usage = fileusage_TextMode;
        auxf-->AUXF_FREF =
            glk_fileref_create_by_name(fileusage_Data + usage,
                Glulx_ChangeAnyToCString(auxf-->AUXF_FILENAME), 0);
        auxf-->AUXF_STATUS = AUXF_STATUS_IS_CLOSED;
    }
    return auxf-->AUXF_FREF;
];
```

§**6. Existence.** Determine whether a file exists on disc. Note that we have no concept of directories, or the file system structure on the host machine: indeed, it is entirely up to the Glulx VM what it does when asked to look for a file. By convention, though, files for a project are stored in the same folder as the story file when out in the wild; when a project is developed within the Inform user interface, they are either (for preference) stored in a `Files` subfolder of the `Materials` folder for a project, or else stored alongside the Inform project file.

```
[ FileIO_Exists auxf  fref;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE)) rfalse;
    fref = FileIO_Fref(auxf);
    return glk_fileref_does_file_exist(fref);
];
```

§**7. Readiness.** One of our problems is that a file might be being used by another application: perhaps even by another story file running in a second incarnation of Glulx, like a parallel world of which we can know nothing. We actually want to allow for this sort of thing, because one use for external files in I7 is as a sort of communications conduit for assisting applications.

Most operating systems solve this problem by means of locking a file, or by creating a second lock-file, the existence of which indicates ownership of the original. We haven't got much access to the file-system, though: what we do is to set the first character of the file to an asterisk to mark it as complete and ready for reading, or to a hyphen to mark it as a work in progress.

`FileIO_Ready` determines whether or not a file is ready to be read from: it has to exist on disc, and to be openable, and also to be ready in having this marker asterisk.

`FileIO_MarkReady` changes the readiness state of a file, writing the asterisk or hyphen into the initial character as needed.

```
[ FileIO_Ready auxf  fref str ch;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE)) rfalse;
    fref = FileIO_Fref(auxf);
    if (glk_fileref_does_file_exist(fref) == false) rfalse;
    str = glk_stream_open_file(fref, filemode_Read, 0);
```

```
    ch = glk_get_char_stream(str);
    glk_stream_close(str, 0);
    if (ch ~= '*') rfalse;
    rtrue;
];
[ FileIO_MarkReady auxf readiness  fref str ch;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to open a non-file");
    fref = FileIO_Fref(auxf);
    if (auxf-->AUXF_STATUS ~= AUXF_STATUS_IS_CLOSED)
        return FileIO_Error(auxf, "only closed files can be marked");
    str = glk_stream_open_file(fref, filemode_ReadWrite, 0);
    glk_stream_set_position(str, 0, 0); ! seek start
    if (readiness) ch = '*'; else ch = '-';
    glk_put_char_stream(str, ch); ! mark as complete
    glk_stream_close(str, 0);
];
```

§8. Open File.

```
[ FileIO_Open auxf write_flag append_flag
    fref str mode ix ch not_this_ifid owner force_header;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to open a non-file");
    fref = FileIO_Fref(auxf);
    if (auxf-->AUXF_STATUS ~= AUXF_STATUS_IS_CLOSED)
        return FileIO_Error(auxf, "tried to open a file already open");
    if (write_flag) {
        if (append_flag) {
            mode = filemode_WriteAppend;
            if (glk_fileref_does_file_exist(fref) == false)
                force_header = true;
        }
        else mode = filemode_Write;
    } else {
        mode = filemode_Read;
        if (glk_fileref_does_file_exist(fref) == false)
            return FileIO_Error(auxf, "tried to open a file which does not exist");
    }
    str = glk_stream_open_file(fref, mode, 0);
    if (str == 0)
        return FileIO_Error(auxf, "tried to open a file but failed");
    auxf-->AUXF_STREAM = str;
    if (write_flag) {
        if (append_flag)
            auxf-->AUXF_STATUS = AUXF_STATUS_IS_OPEN_FOR_APPEND;
        else
            auxf-->AUXF_STATUS = AUXF_STATUS_IS_OPEN_FOR_WRITE;
        glk_stream_set_current(str);
        if ((append_flag == FALSE) || (force_header)) {
            print "- ";
            for (ix=6: ix <= UUID_ARRAY->0: ix++) print (char) UUID_ARRAY->ix;
```

```
            print " ", (string) auxf-->AUXF_FILENAME, "^";
        }
    } else {
        auxf-->AUXF_STATUS = AUXF_STATUS_IS_OPEN_FOR_READ;
        ch = FileIO_GetC(auxf);

                if (ch == ' ') break;
            }
            if (not_this_ifid == false) {
                ch = FileIO_GetC(auxf);
                if (ch ~= ' ') { jump BadFile; }
            }
        }
        while (ch ~= -1) {
            ch = FileIO_GetC(auxf);
            if (ch == 10 or 13) break;
        }
        if (not_this_ifid) {
            auxf-->AUXF_STATUS = AUXF_STATUS_IS_CLOSED;
            glk_stream_close(str, 0);
            return FileIO_Error(auxf,
                "tried to open a file owned by another project");
        }
    }
    return auxf-->AUXF_STREAM;
    .BadFile;
    auxf-->AUXF_STATUS = AUXF_STATUS_IS_CLOSED;
    glk_stream_close(str, 0);
    return FileIO_Error(auxf, "tried to open a file which seems to be malformed");
];
```

§9. Close File.

```
[ FileIO_Close auxf;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to close a non-file");
    if (auxf-->AUXF_STATUS ~=
        AUXF_STATUS_IS_OPEN_FOR_READ or
        AUXF_STATUS_IS_OPEN_FOR_WRITE or
        AUXF_STATUS_IS_OPEN_FOR_APPEND)
        return FileIO_Error(auxf, "tried to close a file which is not open");
    if ((auxf-->AUXF_BINARY == false) &&
        (auxf-->AUXF_STATUS ==
        AUXF_STATUS_IS_OPEN_FOR_WRITE or
        AUXF_STATUS_IS_OPEN_FOR_APPEND)) {
        glk_set_window(gg_mainwin);
    }
    if (auxf-->AUXF_STATUS ==
        AUXF_STATUS_IS_OPEN_FOR_WRITE or
        AUXF_STATUS_IS_OPEN_FOR_APPEND) {
        glk_stream_set_position(auxf-->AUXF_STREAM, 0, 0); ! seek start
        glk_put_char_stream(auxf-->AUXF_STREAM, '*'); ! mark as complete
    }
    glk_stream_close(auxf-->AUXF_STREAM, 0);
    auxf-->AUXF_STATUS = AUXF_STATUS_IS_CLOSED;
];
```

§10. Get Character.

```
[ FileIO_GetC auxf;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE)) return -1;
    if (auxf-->AUXF_STATUS ~= AUXF_STATUS_IS_OPEN_FOR_READ) return -1;
    return glk_get_char_stream(auxf-->AUXF_STREAM);
];
```

§11. Put Character.

```
[ FileIO_PutC auxf char;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to write to a non-file");
    if (auxf-->AUXF_STATUS ~=
        AUXF_STATUS_IS_OPEN_FOR_WRITE or
        AUXF_STATUS_IS_OPEN_FOR_APPEND)
        return FileIO_Error(auxf,
            "tried to write to a file which is not open for writing");
    return glk_put_char_stream(auxf-->AUXF_STREAM, char);
];
```

§**12. Print Line.** We read characters from the supplied file until the next newline character. (We allow for that to be encoded as either a single `0a` or a single `0d`.) Each character is printed, and at the end we print a newline.

```
[ FileIO_PrintLine auxf ch;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to write to a non-file");
    for (::) {
        ch = FileIO_GetC(auxf);
        if (ch == -1) rfalse;
        if (ch == 10 or 13) { print "^"; rtrue; }
        print (char) ch;
    }
];
```

§**13. Print Contents.** Repeating this until the file runs out is equivalent to the Unix command `cat`, that is, it copies the stream of characters from the file to the output stream. (This might well be another file, just as with `cat`, in which case we have a copy utility.)

```
[ FileIO_PrintContents auxf tab;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to access a non-file");
    if (auxf-->AUXF_BINARY)
        return FileIO_Error(auxf, "printing text will not work with binary files");
    if (FileIO_Open(auxf, false) == 0) rfalse;
    while (FileIO_PrintLine(auxf)) ;
    FileIO_Close(auxf);
    rtrue;
];
```

§**14. Print Text.** The following writes a given piece of text as the new content of the file, either as the whole file (if `append_flag` is false) or adding only to the end (if true).

```
[ FileIO_PutContents auxf text append_flag  str ch;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to access a non-file");
    if (auxf-->AUXF_BINARY)
        return FileIO_Error(auxf, "writing text will not work with binary files");
    str = FileIO_Open(auxf, true, append_flag);
    if (str == 0) rfalse;
    @push say__p; @push say__pc;
    ClearParagraphing();
    PrintText(text);
    FileIO_Close(auxf);
    @pull say__pc; @pull say__p;
    rfalse;
];
```

§**15. Serialising Tables.** The most important data structures to "serialise" – that is, to convert from their binary representations in memory into text representations in an external file – are Tables. Here we only carry out the file-handling; the actual translations are in "Tables.i6t".

```
[ FileIO_PutTable auxf tab rv;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to write table to a non-file");
    if (auxf-->AUXF_BINARY)
        return FileIO_Error(auxf, "writing a table will not work with binary files");
    if (FileIO_Open(auxf, true) == 0) rfalse;
    rv = TablePrint(tab);
    FileIO_Close(auxf);
    if (rv) return RunTimeProblem(RTP_TABLE_CANTSAVE, tab);
    rtrue;
];
[ FileIO_GetTable auxf tab;
    if ((auxf == 0) || (auxf-->AUXF_MAGIC ~= AUXF_MAGIC_VALUE))
        return FileIO_Error(auxf, "tried to read table from a non-file");
    if (auxf-->AUXF_BINARY)
        return FileIO_Error(auxf, "reading a table will not work with binary files");
    if (FileIO_Open(auxf, false) == 0) rfalse;
    TableRead(tab, auxf);
    FileIO_Close(auxf);
    rtrue;
];
```

§**16. Z-Machine Stubs.** These routines do the minimum possible, but equally, they only generate a run-time problem when there is no alternative.

```
#IFNOT; ! TARGET_GLULX
[ FileIO_Exists auxf; rfalse; ];
[ FileIO_Ready auxf; rfalse; ];
[ FileIO_GetC auxf; return -1; ];
[ FileIO_PutTable auxf tab;
    return FileIO_Error(auxf, "external files can only be used under Glulx");
];
[ FileIO_MarkReady auxf status; FileIO_PutTable(auxf); ];
[ FileIO_GetTable auxf tab; FileIO_PutTable(auxf); ];
[ FileIO_PrintContents auxf; FileIO_PutTable(auxf); ];
[ FileIO_PutContents auxf; FileIO_PutTable(auxf); ];
#ENDIF; ! TARGET_GLULX
```
