§**58.** Inform allows vague general statements to be made about everything of a given KOV, as here:

A scene is usually recurring.

("Recurring" is an either/or property of scenes.) Knowledge derived from sentences like this needs to be stored somewhere, and this is where:

```
inference **kov_get_knowledge(kind_of_value *kov) {
    if (kov == NULL) return NULL;
    return data_type_get_knowledge(kov->atomic_kov);
}
```

The function kov_get_knowledge is called from 9/inf.

§**59.** When a KOV has the same name as a property, the two are closely identified in Inform, and special handling is needed. This is how we find out:

```
int kov_name_can_coincide_with_property(kind_of_value *kov) {
    if (kov == NULL) return FALSE;
    return data_type_name_can_coincide_with_property(kov->atomic_kov);
}
```

The function kov_name_can_coincide_with_property is called from 6/equal, 8/mass, 9/prop and 9/cmpbp.

§**60.** And here we read, or write, the correspondence between K and P:

```
property_name *kov_get_coinciding_property(kind_of_value *kov) {
    if (kov == NULL) return NULL;
    return data_type_get_coinciding_property(kov->atomic_kov);
}
void kov_set_coinciding_property(kind_of_value *kov, property_name *prn) {
    if (kov == NULL) return;
    data_type_set_coinciding_property(kov->atomic_kov, prn);
}
```

The function kov_get_coinciding_property is called from 2/lexi, 5/mlc, 6/term, 6/pform, 6/equal, 7/tc, 8/refpt, 8/mass, 9/qty, 9/cmpbp and 12/cinv.
The function kov_set_coinciding_property is called from 9/qty.

§**61. Questions about printing.** Each KOV can provide its own I6 routine to print out a value onto screen, in some human-readable format.

```
char *kov_get_name_of_printing_rule(kind_of_value *kov) {
    if (kov == NULL) return "DecimalNumber";
    return data_type_get_name_of_printing_rule(kov->atomic_kov);
}
```

The function kov_get_name_of_printing_rule is called from 5/rel, 5/litp, 9/rsdt, 9/inpw, 12/phsf and 13/test.

§**62.** And it can also provide a variant used when printing out text about an action, where K is the KOV of either the noun or second noun for that action. (This is used in practice to tweak the use of articles slightly when describing objects, and for a few other variations.)

```
char *kov_get_name_of_printing_rule_ACTIONS(kind_of_value *kov) {
    if (kov == NULL) return "DA_Name";
    return data_type_get_name_of_printing_rule_ACTIONS(kov->atomic_kov);
}
```

The function kov_get_name_of_printing_rule_ACTIONS is called from 11/act.

§**63. Questions about understanding.** Some KOVs can be used as tokens in Understand sentences, others can't: thus "[time]" is a valid Understand token, but "[stored action]" is not.

Some KOVs provide have a GPR ("general parsing routine", an I6 piece of jargon) defined somewhere in the template: if so, this returns its name; if not, it returns `NULL`.

```
char *kov_get_explicit_I6_GPR(kind_of_value *kov) {
    if (kov == NULL) internal_error("kov_get_explicit_I6_GPR on null KOV");
    if (is_kova(kov, OBJECT_TY)) internal_error("wrong way to handle object grammar");
    return data_type_get_explicit_I6_GPR(kov->atomic_kov);
}
```

The function kov_get_explicit_I6_GPR is called from 13/gtok and 13/gpr.

§**64.** Can the KOV have a GPR of any kind in the final code?

```
int kov_offers_I6_GPR(kind_of_value *kov) {
    if (kov == NULL) return FALSE;
    return data_type_offers_I6_GPR(kov->atomic_kov);
}
```

The function kov_offers_I6_GPR is called from 7/kix, 13/gtok and 13/gpr.

§**65.** Request that a GPR be compiled for this KOV; the return value tell us whether this will be allowed or not.

```
int kov_request_I6_GPR(kind_of_value *kov) {
    if (kov == NULL) return FALSE;
    if (is_kova(kov, OBJECT_TY)) internal_error("wrong way to handle object grammar");
    return data_type_request_I6_GPR(kov->atomic_kov);
}
```

The function kov_request_I6_GPR is called from 13/tfg and 13/gtok.

§**66.** Do we need to compile a GPR of our own for this KOV?

```
int kov_needs_I6_GPR(kind_of_value *kov) {
    if (kov == NULL) return FALSE;
    return data_type_needs_I6_GPR(kov->atomic_kov);
}
```

The function kov_needs_I6_GPR is called from 13/gprv.

§**67.** If the user writes lines in the source text such as

Understand "eleventy-one" as 111.

then grammar lines will have to be attached to a KOV; in fact, a KOV can have its own `grammar_verb` structure attached, which holds a sequence of such grammar lines. (These are possibilities in addition to those provided by any GPR existing because of the above routines.)

```
void kov_set_parsing_grammar(kind_of_value *kov, grammar_verb *gv) {
    if (kov == NULL) return;
    if (is_kova(kov, OBJECT_TY)) internal_error("wrong way to handle object grammar");
    data_type_set_parsing_grammar(kov->atomic_kov, gv);
}
grammar_verb *kov_get_parsing_grammar(kind_of_value *kov) {
    if (kov == NULL) return NULL;
    if (is_kova(kov, OBJECT_TY)) internal_error("wrong way to handle object grammar");
    return data_type_get_parsing_grammar(kov->atomic_kov);
}
```

The function kov_set_parsing_grammar is called from 13/gv.

The function kov_get_parsing_grammar is called from 13/gv and 13/gprv.

§**68.** For the following, see the explanation in "Indexed Texts.i6t" in the template: a recognition-only GPR is used for matching specific data in the course of parsing names of objects, but not as a grammar token in its own right.

```
char *kov_get_recognition_only_GPR(kind_of_value *kov) {
    if (kov == NULL) return NULL;
    return data_type_get_recognition_only_GPR(kov->atomic_kov);
}
```

The function kov_get_recognition_only_GPR is called from 13/tfg and 13/gpr.

§69. Questions about naming. The source name is that of the data type ID: for instance, `LIST_OF_TY` or `NUMBER_TY`.

```
char *kov_get_NI_source_name(kind_of_value *kov) {
    if (kov == NULL) return "UNKNOWN";
    return type_ID_get_source_name(kov->atomic_kov);
}
void kov_write_source_name_to_file(OUTPUT_STREAM, kind_of_value *kov) {
    if (kov == NULL) WRITE("UNKNOWN");
    else type_ID_write_source_name_to_file(OUT, kov->atomic_kov);
}
```

The function kov_get_NI_source_name is called from 10/tab and 11/act.
The function kov_write_source_name_to_file is called from 12/phsf.

§**70.** The name as used in the source text is the one which users are more familiar with: "table", "scene", "indexed text" and so on.

For efficiency reasons (and to help disambiguate matters since words like "table" are also often used in other contexts) each KOV can have either a single-word name (the "parsing name") or a multi-word name (the "long name"), and these are stored in different forms.

```
vocabulary_entry *kov_get_parsing_name(kind_of_value *kov) {
    if (kov == NULL) return NULL;
    return type_ID_get_singular_parsing_name(kov->atomic_kov);
}
kind_of_value *kov_parse_long_name(int w1, int w2) {
    int t = data_type_parse_long_name(w1, w2);
    if (t != UNKNOWN) return kova(t);
    return NULL;
}
```

The function kov_get_parsing_name is called from 9/qty and 11/act.
The function kov_parse_long_name is called from 5/candd.

§**71.** That means we need an easy way to read the name without having to know which version is used, and it's convenient to combine that with the option to read a pluralised form:

```
void kov_get_name(kind_of_value *kov, int *w1, int *w2, int plural_form) {
    world_object *k;
    if (kov == NULL) { *w1 = -1; *w2 = -1; return; }
    k = kovko_get_kind(kov);
    if ((k) && (k->word_ref1 >= 0)) {
        *w1 = k->word_ref1; *w2 = k->word_ref2;
        if (plural_form) { make_plural_of(*w1, *w2, NULL); *w1 = plw1; *w2 = plw2; }
        return;
    }
    type_ID_copy_name(kov->atomic_kov, w1, w2);
    if (plural_form) { make_plural_of(*w1, *w2, NULL); *w1 = plw1; *w2 = plw2; }
}
```

The function kov_get_name is called from 2/index, 2/lexi, 5/litp, 9/rsdt, 9/qty, 9/pp and 11/act.

§**72.** These human-readable names are also the ones used in the index and in problem messages.

```
void copy_kov_to_string(kind_of_value *kov, char *to, int plural_form) {
    TEMPORARY_STREAM;
    copy_kov_to_string_inner(kov, TEMP, plural_form);
    truncated_strcpy(to, STREAM_TEXT(TEMP), 200);
    CLOSE_TEMPORARY_STREAM;
}
void copy_kov_to_string_inner(kind_of_value *kov, OUTPUT_STREAM, int plural_form) {
    int w1, w2;
    if (kov == NULL) { WRITE("something"); return; }
    if (is_kova(kov, ANY_VALUE_TY)) {
        if (plural_form) WRITE("values"); else WRITE("a value");
        return;
    }
    if ((is_kova(kov, OBJECT_TY)) && (kovko_get_kind(kov) == NULL)) {
        if (plural_form) { WRITE("objects"); return; }
    }
    kov_get_name(kov, &w1, &w2, plural_form);
    if (w1 >= 0) {
        int i, f = FALSE;
        if (plural_form == FALSE) {
            char c = *(lw_array[w1].lw_text);
            if ((c=='a')||(c=='e')||(c=='i')||(c=='o')||(c=='u')) WRITE("an ");
            else WRITE("a ");
        }
        for (i=w1; i<=w2; i++) {
            if (f) WRITE(" "); f = TRUE;
            WRITE("%s", lw_array[i].lw_text);
        }
    } else WRITE("%s", kov_get_description(kov));
    if (data_type_is_constructor(kov->atomic_kov)) {
        WRITE(" ");
        copy_kov_to_string_inner(kov->kc_args[0], OUT, TRUE);
    }
}
```

The function copy_kov_to_string is called from 5/bp, 5/aph, 7/vasp and 7/stsp.

§**73. Questions about indexing.** Every KOV can provide a more human-readable description of what it is: for instance, “a number”.

```
char *kov_get_description(kind_of_value *kov) {
    if (kov == NULL) return "something";
    return type_ID_get_description(kov->atomic_kov);
}
```

The function kov_get_description is called from 2/index.

§**74.** And every KOV is allowed to have the specification pseudo-property – a little text used only on the index pages, and not existing at run-time. This is set explicitly in the source text, but initialised for built-in KOVs from the template file “Types.i6t”.

```
void kov_set_specification_text(kind_of_value *kov, char *desc) {
    data_type_set_specification_text(kov->atomic_kov, desc);
}
char *kov_get_specification_text(kind_of_value *kov) {
    if (kov == NULL) internal_error("can't get specification of null KOV");
    return data_type_get_specification_text(kov->atomic_kov);
}
```

The function kov_set_specification_text is called from 8/mass.
The function kov_get_specification_text is called from 7/kix.

Data Types 7/data

Purpose

To manage the built-in set of data types, which are used as the atomic kinds of value and therefore characterise fundamental kinds of data – numbers, times, texts, and so on – and to create new ones as required.

Definitions

¶1. Data types are ID numbers used to provide a meaning for a `kind_of_value` structure – see "Table of ID Numbers". In this section, we maintain a database of the characteristics associated with each data type. This provides a back-end service for the section managing kinds of value, which is what the rest of Inform communicates with when it wants to know about the nature of values.

When we talk about a SP below as a constant `NUMBER_TY`, say, what we mean is that it is an actual not generic specification, that it has family `VALUE_FMY` and species `CONSTANT_SPC`, and that its associated kind of value is `kova(NUMBER_TY)`, that is, the atomic kind of value corresponding to `NUMBER_TY`.

¶2. Coincidence of data types and properties occurs where a data type has the same name exactly as a property, allowing the same name to be used grammatically in two different contexts. We say that the data type and the property "coincide".

None of the built-in data types coincides with any of the built-in properties, but designed ones often do. This arises from source text such as

> Brightness is a kind of value. The brightnesses are guttering, weak, radiant and blazing. The lantern has a brightness. The lantern is blazing.

Here "brightness" becomes the name of a new type ID; there are only four possible values for this type, with names as given; but "brightness" also becomes the name of a property held by the lantern, whose value is, of course, always a brightness. Inform 7 therefore understands "The lantern is blazing" as a statement about the brightness *property* of the lantern, not as an attempt to equate two incomparable values.

¶3. There are four basic constant compilation methods used:

define `NONE_CCM 1` *constant values of this kind cannot exist*
define `LITERAL_CCM 2` *the literal-parser is used to resolve text of SP to a number*
define `QUANTITATIVE_CCM 3` *a quantity structure is pointed to*
define `SPECIAL_CCM 4` *special code specific to the kind of value is needed*

¶4. Different data types have different abilities: some can be stored in local variables, some cannot, and so forth. This is a great big bag of properties, almost all set by commands to the type interpreter.

```
define MAX_MODIFYING_ADJECTIVES 10
define MAX_WORDS_IN_TYPE_NAME 10
define LOWEST_INDEX_PRIORITY 100

typedef struct data_type_id_rules {
    int data_type_these_apply_to;                                   standard I7 type number
    int defined_in_source_text;                                     rather than by the Types.i6t file
    int named_values_created_with_assertions;                       such as "Train Arrival is a scene."
    int is_incompletely_defined;                                    newly defined type ambiguous as yet
    int is_constructor;                                             is a constructor like "list of..." rather than a base type
    int is_template_variable;                                       is a variable type used in a phrase specification
    int template_variable_number;                                   1, 2, 3, ... for variables; −1, −2, −3, ... references
    int is_a_unit;                                                  a seminumerical data type with literal constant patterns
    int is_an_enumeration;                                          a data type with only named enumerated values
    int quasinumerical;                                             can be used in arithmetic
    int used_in_let_without_casts;                                  can a let variable always have this as its kind?
    int can_be_type_of_global_variable;                             similarly
    int unassignable;                                               can the typechecker allow this to be assigned to storage?
    int constant_compilation_method;                                one of the values below
    int uses_signed_comparisons;                                    when sorting table entries
    int can_exchange;                                               with external files and therefore other story files
    char *default_value;                                            if so, then an I6 value, for built-in types
    char *index_default_value;                                      and its description in the Kinds index
    int index_priority;                                             from 1 (highest) to LOWEST_INDEX_PRIORITY (lowest)
    int indexed_grey_if_empty;                                      shaded grey in the Kinds index
    int block_data;                                                 TRUE for large values stored on the heap
    int multiple_block;                                             TRUE for flexible-size values stored on the heap
    int native_constants;                                           TRUE if uncast constants can be parsed of this type
    int heap_size_estimate;                                         typical number of bytes used
    int next_free_value;                                            to make distinguishable constants belonging to the type
    int has_i6_GPR;                                                 a general parsing routine exists in the I6 code for this
    int I6_GPR_needed;                                              and is actually required
    char *explicit_i6_GPR;                                          routine name, when not compiled automatically
    char *recognition_only_GPR;                                     for recognising an explicit value as preposition
    char *distinguisher;                                            I6 routine to see if values distinguishable in parsing
    struct grammar_verb *understand_as_values;                      used when parsing such values
    struct literal_pattern *ways_to_write_literals;                 list of ways to write this
    int can_coincide_with_property;                                 allowed to coincide in name with a property
    struct property_name *coinciding_property;                      property of the same name, if any
    char dt_I6_identifier[32];                                      an I6 identifier used for compiling printing rules
    char name_of_printing_rule_ACTIONS[32];                         ditto but for ACTIONS testing command
    struct dimensional_rules dim_rules;                             how arithmetic operations work here
    char *specification_text;                                       text for specification
    int no_words_in_exotic_name;                                    where by exotic we mean multi-word but built in
    struct vocabulary_entry *words_in_exotic_name[MAX_WORDS_IN_TYPE_NAME];   ditto
    int no_words_in_exotic_plural;                                  where by exotic we mean multi-word but built in
    struct vocabulary_entry *words_in_exotic_plural[MAX_WORDS_IN_TYPE_NAME];  ditto
    struct data_type_casting_rule *first_casting_rule;              list of these
    struct unit_sequence dimensional_form;                          dimensions of this KOV
    int dimensional_form_fixed;                                     whether they are derived
    struct data_type_comparison_schema *first_comparison_schema;    list of these
```

```
    int no_modifying_adjectives;                                    which can be used in creation
    struct vocabulary_entry *modifying_adjectives[MAX_MODIFYING_ADJECTIVES];   ditto
    struct inference *dt_knowledge;                                 inferences about properties
    char *loop_domain_schema;                                       how to compile an I6 loop over the instances
    char *documentation_reference;                                  documentation symbol, if any
    MEMORY_MANAGEMENT
} data_type_id_rules;
```

The structure data_type_id_rules is shared with 7/dti.

---

§**1.** Take a deep breath and...

```

```
    dtid->unassignable = FALSE;
    dtid->understand_as_values = NULL;
    dtid->used_in_let_without_casts = FALSE;
    dtid->uses_signed_comparisons = FALSE;
    dtid->ways_to_write_literals = NULL;

    dtid->dimensional_form = data_spec_to_unit_sequence(t);
    dtid->dimensional_form_fixed = FALSE;

    strcpy(dtid->dt_I6_identifier, "DecimalNumber");
    strcpy(dtid->name_of_printing_rule_ACTIONS, "DecimalNumber");
    dim_initialise(&(dtid->dim_rules));
    play_back_type_macro(parse_type_macro_name("#DEFAULTS"), dtid);
    return dtid;
}
```

The function dtid_new is called from 7/dti.

§2. Two special sorts of data type.

```
int data_type_is_constructor(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return FALSE;
    if (dtid->is_constructor) return TRUE;
    return FALSE;
}
```

The function data_type_is_constructor is called from 7/kov and 7/kix.

§3. See the discussion of KOV casting in "Kinds of Value".

```
int data_type_template_variable_number(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return 0;
    return dtid->template_variable_number;
}
```

The function data_type_template_variable_number is called from 7/kov.

§**4. Initial creation of new data types.** The following routine performs the initial, incomplete creation of a new data type: it is what happens when an assertion like "Weight is a kind of value." is read. The `#NEW` type macro defined in "Types.i6t" sets all of the properties of the kind except those pertaining to its name. (That includes the question of whether it coincides with a property, since this is specified by giving a common name to both.)

```
int new_data_type(int w1, int w2) {
    if (is_word_intermediate(of_V, w1, w2) >= 0)
        ⟨Weasel out at the thought of "of" in a KOV 5⟩;
    int new_id = type_ID_claim_new_ID();
    data_type_id_rules *dtid = dtid_new(new_id);
    type_ID_set_name(new_id, w1, w2);
    isn_compose_identifier(dtid->dt_I6_identifier, 'T', (dtid->allocation_id)+1, w1, w2);
    strcpy(dtid->name_of_printing_rule_ACTIONS, dtid->dt_I6_identifier);
    play_back_type_macro(parse_type_macro_name("#NEW"), dtid);
    property_name *prn = parse_property_name(w1, w2);
    if (prn) {
        kind_of_value *kov = kova(new_id);
        prn_set_kind_of_value(prn, kov);
        make_type_coincident(kov, prn);
    }
    LOGIF(TYPE_CREATIONS, "Created designed type %d: $W\n", new_id, w1, w2);
    return new_id;
}
```

The function new_data_type is called from 7/kov.

§**5.** This is just a tiny bit pusillanimous. It avoids ambiguities arising if we create a property called, say, "point of view" and then make that coincide with a KOV. But in an ideal world, we ought to allow such things.

⟨Weasel out at the thought of "of" in a KOV 5⟩ ≡

```
    quote_source(1, current_sentence);
    quote_words(2, w1, w2);
    handmade_problem(_P_(C7KindOfValueWithOf));
    issue_problem_segment(
        "You wrote %1, but that would mean creating a kind of value "
        "'%2' which contains the word 'of' - this is disallowed because "
        "it creates just too many grammatical ambiguities down the road. "
        "Apologies for the inconvenience.");
    issue_problem_end();
    return -1;
```

This code is used in §4.

§**6. Questions about origin.** Some data types are built in (in that the template file "Types.i6t" creates them, using the type interpreter), while others arise from "X is a kind of value" sentences in the source text:

```
int data_type_is_built_in(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    if (dtid->defined_in_source_text) return FALSE;
    return TRUE;
}
```

The function data_type_is_built_in is called from 7/kov.

§**7.** A few types support modifying adjectives when created. These adjectives are created in the "Types.i6t" file, and parsed here.

```
int data_type_parse_modifying_adjectives(int t, int w1, int w2) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    int i;
    if (dtid == NULL) return -1;
    if (w1 != w2) return -1;
    for (i=0; i<dtid->no_modifying_adjectives; i++)
        if (compare_word(w1, dtid->modifying_adjectives[i]))
            return i;
    return -1;
}
```

The function data_type_parse_modifying_adjectives is called from 7/kov.

§**8. Questions about constants of this kind.** Some KOVs have named constants, others use a quasi-numerical notation: for instance "maroon" might be a named constant for KOV "colour", while "234 kilopascals" might be a notation for a KOV where constants are not named.

```
int data_type_has_named_constant_values(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    if (dtid->named_values_created_with_assertions) return TRUE;
    return FALSE;
}
```

The function data_type_has_named_constant_values is called from 7/kov.

§**9.** The following returns the compilation method: a constant in the form `*_CCM`, defined above.

```
int data_type_get_constant_compilation_method(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->constant_compilation_method;
}
```

The function data_type_get_constant_compilation_method is called from 7/kov.

§**10.** Declares that the given notation can be used to write constants of this data type.

```
void data_type_add_literal_form(int t, literal_pattern *lp) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    dtid->ways_to_write_literals =
        lp_list_add(dtid->ways_to_write_literals, lp);
}
```

The function data_type_add_literal_form is called from 7/kov.

§**11.** Returns the list of LPs attached.

```
literal_pattern *data_type_list_of_literal_forms(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->ways_to_write_literals;
}
```

The function data_type_list_of_literal_forms is called from 5/litp, 7/kov, 7/dim and 7/kix.

§**12. Questions about range and behaviour.** For explanation, see the corresponding paragraphs of "Kinds of Value".

```
int data_type_uses_signed_comparisons(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->uses_signed_comparisons;
}
int data_type_requires_blanks_bitmap(int t) {
    if (t == OBJECT_TY) return FALSE;
    if (data_type_is_an_enumeration(t)) return FALSE;
    return TRUE;
}
int data_type_get_highest_valid_value_as_integer(int t) {
    switch (t) {
        case ACTION_NAME_TY: return NUMBER_CREATED(action_name);
        case ACTIVITY_TY: return NUMBER_CREATED(activity);
        case EXTERNALFILE_TY: return NUMBER_CREATED(external_file);
        case FIGURENAME_TY: return NUMBER_CREATED(blorb_figure);
        case RULE_TY: return NUMBER_CREATED(booked_rule);
        case RULEBOOK_TY: return NUMBER_CREATED(rulebook);
        case SOUNDNAME_TY: return NUMBER_CREATED(blorb_sound);
        case TABLE_TY: return NUMBER_CREATED(table) + 1;
        case TRUTH_STATE_TY: return 2;
    }
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->next_free_value - 1;
}
```

The function data_type_uses_signed_comparisons is called from 7/kov and 9/rsdt.
The function data_type_requires_blanks_bitmap is called from 7/kov.
The function data_type_get_highest_valid_value_as_integer is called from 7/kov and 7/kix.

§**13.** The dimensional rules for t are the conventions on whether arithmetic operations can be applied, and if so, what KOV the result has.

```
dimensional_rules *dtid_get_dim_rules(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return NULL;
    return &(dtid->dim_rules);
}
int data_type_is_quasinumerical(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return FALSE;
    return dtid->quasinumerical;
}
unit_sequence *data_type_get_unit_sequence(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return NULL;
    return &(dtid->dimensional_form);
}
int data_type_test_if_derived(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return TRUE;
```

```
    return dtid->dimensional_form_fixed;
}

void data_type_now_derived(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) internal_error("can't fix dim form for null data type");
    dtid->dimensional_form_fixed = TRUE;
}
```

The function dtid_get_dim_rules is called from 7/dim.
The function data_type_is_quasinumerical is called from 7/kov and 7/dim.
The function data_type_get_unit_sequence is called from 7/kov and 7/dim.
The function data_type_test_if_derived is called from 7/dim.
The function data_type_now_derived is called from 7/dim.

§**14.** Some data types can be stored in global variables (and properties), others not: this is a straightforward matter, with the specification of each type explicitly giving a yes/no response. The issue is simple here because global variables and properties have their types declared exactly by name, so that Inform is never unsure what type they have. The routine below is used to decided whether creation of a global variable of kind t should be permitted. (Once it exists, casting means that it may well contain values of other kinds – for instance, a `TEXT` variable may well contain a `TEXT_ROUTINE` value, but a `TEXT_ROUTINE` variable is not permitted to exist.)

```
int data_type_can_be_stored_in_variables(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->can_be_type_of_global_variable;
}
```

The function data_type_can_be_stored_in_variables is called from 7/kov and 9/rsdt.

§**15.** Similarly, some data can be stored in local ("let") variables. But because of the way let variables are ambiguously defined – by initial value rather than by an explicit type description – we need to know which are the more likely possibilities, and that likelihood order is provided by the global array defined below. (There will typically only be seven such options, so the array below is plenty.)

Suppose we read "let X be V", where X is an unknown name: Inform creates X as a variable and takes the type from V. Or does it? If the KOV K of V has "used-in-let-without-casts" set, X is immediately set to K. Otherwise Inform attempts to cast V to one of the types with a "used-in-let-with-cast-priority" set, starting with the lowest priority and working up, until the first match. For instance:

```
let X be "look, it's [time of day]";
```

has K equal to `kova(TEXT_ROUTINE_TY)`, but this is not permitted as the type of a let variable, so Inform tries various possibilities, and the lowest-priority-number match is `kova(TEXT_TY)`.

It follows that, as with `kova(TEXT_ROUTINE)`, any KOV for a data type with neither property specified is never the type of any let variable.

define `MAX_LET_CAST_OPTIONS 64`

```
int no_let_cast_options = 0;
int data_types_in_let_variables[MAX_LET_CAST_OPTIONS];
int let_cast_priority_levels[MAX_LET_CAST_OPTIONS];

void initialise_let_casting_options(void) {
    register_let_cast_option(-1, 10000);
}

void register_let_cast_option(int t, int priority) {
    int i, j;
```

```
    if (no_let_cast_options == MAX_LET_CAST_OPTIONS)
        internal_error("too many let cast options");
    for (i=0; i<no_let_cast_options; i++)
        if (priority < let_cast_priority_levels[i]) {
            for (j=no_let_cast_options; j>i; j--) {
                data_types_in_let_variables[j] =
                    data_types_in_let_variables[j-1];
                let_cast_priority_levels[j] =
                    let_cast_priority_levels[j-1];
            }
            data_types_in_let_variables[i] = t;
            let_cast_priority_levels[i] = priority;
            no_let_cast_options++;
            return;
        }
    data_types_in_let_variables[no_let_cast_options] = t;
    let_cast_priority_levels[no_let_cast_options++] = priority;
}
int data_type_for_storage_to_hold(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    int j;
    if (dtid->used_in_let_without_casts) return t;
    for (j=0; data_types_in_let_variables[j] >= 0; j++) {
        if (data_type_allow_cast(data_types_in_let_variables[j], t)
            == ALWAYS_MATCH)
            return data_types_in_let_variables[j];
    }
    return UNKNOWN;
}
```

The function initialise_let_casting_options is called from 7/dti.
The function register_let_cast_option is called from 7/dti.
The function data_type_for_storage_to_hold is called from 7/kov.

§**16.** Most values are such that the typechecker will allow at least an attempt to assign them to variables, even if that later leads to a problem message; but in a few cases we forbid this even as an interpretation of the source text's wishes. (This enables us to avoid ambiguities.)

```
int data_type_unassignable(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->unassignable;
}
```

§**17. Questions about the default value.** For explanation, see the corresponding paragraphs of "Kinds of Value".

```
char *data_type_get_default_value_of_type(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->default_value;
}
char *data_type_get_index_default_value(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->index_default_value;
}
```

The function data_type_get_default_value_of_type is called from 7/kov.
The function data_type_get_index_default_value is called from 7/kov.

§18. Questions about quantification. For explanation, see the corresponding paragraphs of "Kinds of Value".

```
int data_type_compile_domain_possible(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    if (data_type_is_an_enumeration(t)) return TRUE;
    if (dtid->loop_domain_schema) return TRUE;
    return FALSE;
}
```

The function data_type_compile_domain_possible is called from 7/kov.

§19. At some stage these should probably move into the "Types.i6t" template file.

```
define MAX_LOOP_DOMAIN_SCHEMA_LENGTH 1000

int data_type_write_loop_schema(i6_schema *sch, int t, int use_ix) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    char *p = dtid->loop_domain_schema;
    char q[MAX_LOOP_DOMAIN_SCHEMA_LENGTH+4];
    if (data_type_is_an_enumeration(t)) {
        sch_write_to_existing_1d(sch,
            "for (*1=1: *1<=%d: *1++)", data_type_get_highest_valid_value_as_integer(t));
        return TRUE;
    }
    if (p == NULL) return FALSE;
    if (use_ix) ⟨Convert all references to term 2 to term 1 plus "ix" 20⟩
    else strcpy(q, p);
    sch_write_to_existing(sch, q);
    return TRUE;
}
```

The function data_type_write_loop_schema is called from 7/kov.

§20. Oh, but this is a vulgar little trick. The domain schemas set in "Types.i6t" refer to two variables, `*1` and `*2`. `*1` is the current instance in the loop body, and `*2` is free for the loop header to use – typically it is a counter iterating through some table of values from which `*1` is drawn. But sometimes we need to expand to `*1` and `*1` with `_ix` suffixed, instead of general terms `*1` and `*2`. (For instance, to `x` and `x_ix`: the suffix is supposed to mean "indexer".) Rather than fix this in any elegant way, we just hack the schema as we write it.

⟨Convert all references to term 2 to term 1 plus "ix" 20⟩ ≡

```
    int i, j;
    for (i=0, j=0; (p[i]) && (i<MAX_LOOP_DOMAIN_SCHEMA_LENGTH); i++)
        if ((use_ix) && (i>0) && (p[i-1] == '*') && (p[i] == '2')) {
            q[j++] = '1'; q[j++] = '_'; q[j++] = 'i'; q[j++] = 'x';
        } else q[j++] = p[i];
    q[j] = 0;
```

This code is used in §19.

§**21. Questions about run-time storage.** For explanation, see the corresponding paragraphs of "Kinds of Value".

```
int data_type_has_pointer_value_constants(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return FALSE;
    if (dtid->native_constants) return TRUE;
    return FALSE;
}

int data_type_uses_pointer_values(int t) {
    data_type_id_rules *dtid;
    if (t == UNKNOWN) return FALSE;
    dtid = type_ID_get_dtid(t);
    return dtid->block_data;
}

int data_type_get_heap_size_estimate(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->heap_size_estimate;
}

int data_type_allow_word_as_pointer(int left, int right) {
    if (data_type_uses_pointer_values(left) == FALSE) return FALSE;
    if (data_type_uses_pointer_values(right) == TRUE) return FALSE;
    if (data_type_allow_cast(left, right) == ALWAYS_MATCH) return TRUE;
    return FALSE;
}
```

The function data_type_has_pointer_value_constants is called from 7/kov.

The function data_type_uses_pointer_values is called from 7/kov and 9/rsdt.

The function data_type_get_heap_size_estimate is called from 7/kov.

The function data_type_allow_word_as_pointer is called from 7/kov.

§**22. Questions about copying and comparing.** What happens at run-time when we test to see if value V equals value W, or change storage object S so that it now contains value T, depends on the kind of values we are discussing. If there were only word-based values in Inform (as was the case until September 2007), there would be little to do here, as the comparison would simply compile to `V == W`, while the storage would be a matter of either `S = W;` or some more exotic case along the lines of `StorageRoutineWrite(S, W);`.

But once pointers to blocks are allowed, this becomes more interesting. Now the comparison needs to be a deep one, that is, we want to test whether two indexed texts (say) have the same textual content – not whether we are holding two pointers to the same blocks in memory, which is what a simple comparison would achieve. Such a test is called "deep comparison", and similarly, we must assign by transferring the contents of the blocks of data, not merely the pointer to them, which is a "deep copy". This turns out to be one of the convenient places to perform any explicit casts between mere word values and block data, too: see above. (The other place explicit casting is needed is during transfer of arguments to functions and other phrases, and this happens during invocation compilation.)

```
char *data_type_interpret_test_equality(int left, int right) {
    LOGIF(TYPE_CASTS, "Finding ST == with kovs $s, $s\n", left, right);
    char *special_rule = data_type_find_comparison_schema(left, right);
    if (special_rule) return special_rule;
    if (data_type_uses_pointer_values(left)) {
        if (data_type_allow_word_as_pointer(left, right)) {
            pointer_allocation *pall =
                phsf_add_allocation(kova(left),
                    "*=-BlkValueCompare(*1, BlkValueCast(*##, *#1, *#2, *!2))==0");
            return pall_get_expanded_schema(pall);
        }
        return "*=-BlkValueCompare(*1, *2)==0";
    }
    return "*=-*1 == *2";
}
char *data_type_interpret_store(int storage_class, int L, int R) {
    if (data_type_uses_pointer_values(L)) {
        if (data_type_allow_word_as_pointer(L, R))
            return storage_class_schema(storage_class, STORE_WORD_TO_POINTER);
        return storage_class_schema(storage_class, STORE_POINTER_TO_POINTER);
    }
    return storage_class_schema(storage_class, STORE_WORD_TO_WORD);
}
```

The function data_type_interpret_test_equality is called from 7/kov.
The function data_type_interpret_store is called from 7/kov.

§**23.** And the following returns an I6 routine to determine if two values differ:

```
char *data_type_get_distinguisher(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->distinguisher;
}
```

The function data_type_get_distinguisher is called from 7/kov.

§**24.** Can values be written out to an external file and retrieved by some other Inform story file, or by this one running on a different day?

```
int data_type_can_exchange(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->can_exchange;
}
```

The function data_type_can_exchange is called from 7/kov.

§25. Questions about implicit casting. For explanation, see the corresponding paragraphs of "Kinds of Value".

Inform uses the term "casting" in a slightly more specific way than its usual definition in compiler theory. We say that X casts to Y if a value of kind X can be used as if it were of kind Y. The cast is said to be implicit if no change is required to the run-time value of X to make it into a Y; explicit if some conversion code must be run. Clearly any type X casts implicitly to itself.

Given Y (the left-hand type) and X (the right-hand – thinking of this as being a way to check an assignment to a variable), the following decides whether a cast can be made always, never or sometimes. Sometimes means that the compiler will allow an implicit cast, but will generate run-time code to check the validity then. (For instance, rulebook always casts to rule because all rulebook values at run-time are valid as rule values: but rule only sometimes casts to rulebook, because only some rule values are rulebook values.)

Inform's convention is that all casts between word values must be implicit, while all casts from word values to block values are explicit. The routine below does not concern itself with this.

Finally, note that this implementation does not automatically make the casting relation transitive: if X casts to Y, and Y casts to Z, then it ought to be true that X casts to Z, but such a deduction is not made. So we need to set up the casting definitions in the `Types.i6t` file carefully to ensure this by hand.

```
int data_type_allow_cast(int left, int right) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(left);
    data_type_casting_rule *dtcr;
    if (left == right) return ALWAYS_MATCH;
    if (dtid == NULL) return NEVER_MATCH;
    dtcr = dtid->first_casting_rule;
    while (dtcr) {
        switch(dtcr->cast_domain) {
            case CAST_SPECIFIC:
                if (right == dtcr->single_value_casts) return dtcr->casting_certainty;
                break;
            case CAST_UNIVERSAL:
                return ALWAYS_MATCH;
            case CAST_ASSIGNABLE:
                if (data_type_unassignable(right)) return NEVER_MATCH;
                return ALWAYS_MATCH;
            case CAST_ANY_WORD:
                if (data_type_uses_pointer_values(right) == FALSE) return ALWAYS_MATCH;
                break;
            case CAST_ANY_POINTER:
                if (data_type_uses_pointer_values(right) == TRUE) return ALWAYS_MATCH;
                break;
        }
        dtcr = dtcr->next_casting_rule;
    }
    return NEVER_MATCH;
}
```

The function data_type_allow_cast is called from 7/kov.

§**26.** And similarly for extracting any special schema needed to test whether a value of K_L "is" a value of K_R:

```
char *data_type_find_comparison_schema(int left, int right) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(left);
    data_type_comparison_schema *dtcs;
    if (dtid == NULL) return NULL;
    dtcs = dtid->first_comparison_schema;
    while (dtcs) {
        if (right == dtcs->comparator) return dtcs->comparison_schema;
        dtcs = dtcs->next_comparison_schema;
    }
    return NULL;
}
```

§**27. Questions about units and enumerations.** On creation, a new data type has not yet decided what it is going to be like: perhaps an enumeration, perhaps a unit, and in future perhaps other possibilities too. Initially, then, it has an incompletely defined flag set: once one of the conversion routines has been used, the matter is settled and there is no going back.

```
int data_type_is_uncertainly_defined(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->is_incompletely_defined;
}
```

The function data_type_is_uncertainly_defined is called from 7/kov.

§**28.** Here we test for being a unit or an enumeration:

```
int data_type_is_a_unit(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->is_a_unit;
}
int data_type_is_an_enumeration(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return FALSE;                    to facilitate a problem message elsewhere
    return dtid->is_an_enumeration;
}
```

The function data_type_is_a_unit is called from 7/kov.
The function data_type_is_an_enumeration is called from 7/kov.

§**29.** Conversions to a unit or enumeration require running macros in the type interpreter:

```
int data_type_convert_to_unit(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    if (dtid->is_incompletely_defined == TRUE) {
        play_back_type_macro(parse_type_macro_name("#UNIT"), dtid);
        return TRUE;
    }
    if (dtid->is_a_unit) return TRUE;
    return FALSE;
}
int data_type_convert_to_enumeration(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    if (dtid->is_incompletely_defined == TRUE) {
        play_back_type_macro(parse_type_macro_name("#ENUMERATION"), dtid);
        return TRUE;
    }
    if (dtid->is_an_enumeration) return TRUE;
    return FALSE;
}
```

The function data_type_convert_to_unit is called from 7/kov.
The function data_type_convert_to_enumeration is called from 7/kov.

§**30.** Allocating a new instance number:

```
int data_type_new_enumerated_value(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->next_free_value++;
}
```

The function data_type_new_enumerated_value is called from 7/kov.

§**31. Questions about properties.** For explanation, see the corresponding paragraphs of "Kinds of Value".

```
inference **data_type_get_knowledge(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid_or_null(t);
    if (dtid == NULL) return NULL;
    return &(dtid->dt_knowledge);
}
```

The function data_type_get_knowledge is called from 7/kov.

§**32.** When a KOV coincides with a property:

```
int data_type_name_can_coincide_with_property(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->can_coincide_with_property;
}
void data_type_set_coinciding_property(int t, property_name *pn) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    dtid->coinciding_property = pn;
}
property_name *data_type_get_coinciding_property(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->coinciding_property;
}
```

The function data_type_name_can_coincide_with_property is called from 7/kov.
The function data_type_set_coinciding_property is called from 7/kov.
The function data_type_get_coinciding_property is called from 7/kov.

§**33. Questions about printing.** An I6 routine to print out a value onto screen:

```
char *data_type_get_name_of_printing_rule(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->dt_I6_identifier;
}
```

The function data_type_get_name_of_printing_rule is called from 7/kov and 9/rsdt.

§**34.** And one to describe a value in an action:

```
char *data_type_get_name_of_printing_rule_ACTIONS(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->name_of_printing_rule_ACTIONS;
}
```

The function data_type_get_name_of_printing_rule_ACTIONS is called from 7/kov.

§35. Questions about understanding. For explanation, see the corresponding paragraphs of "Kinds of Value".

```
char *data_type_get_explicit_I6_GPR(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->explicit_i6_GPR;
}
```

The function data_type_get_explicit_I6_GPR is called from 7/kov.

§36. Can this have a GPR of any kind in the final code?

```
int data_type_offers_I6_GPR(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->has_i6_GPR;
}
```

The function data_type_offers_I6_GPR is called from 7/kov.

§37. Request that a GPR be compiled; the return value tell us whether this will be allowed or not.

```
int data_type_request_I6_GPR(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    if (dtid->has_i6_GPR == FALSE) return FALSE;                    can't oblige
    dtid->I6_GPR_needed = TRUE;                                     make note to oblige later
    return TRUE;
}
```

The function data_type_request_I6_GPR is called from 7/kov.

§38. Do we need to compile a GPR of our own?

```
int data_type_needs_I6_GPR(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->I6_GPR_needed;
}
```

The function data_type_needs_I6_GPR is called from 7/kov.

§39. The GV attached to a data type, and from which its GPR will be compiled.

```
void data_type_set_parsing_grammar(int t, grammar_verb *gv) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    dtid->understand_as_values = gv;
}
grammar_verb *data_type_get_parsing_grammar(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->understand_as_values;
}
```

The function data_type_set_parsing_grammar is called from 7/kov.
The function data_type_get_parsing_grammar is called from 7/kov.

§**40.** A recognition-only GPR.

```
char *data_type_get_recognition_only_GPR(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->recognition_only_GPR;
}
```

The function data_type_get_recognition_only_GPR is called from 7/kov.

§41. Questions about naming. For explanation, see the corresponding paragraphs of "Kinds of Value". For the most part, a kind of value has a singular and a plural form of its name. This is stored either as a single word (where we can use a vocabulary flag to spot it quickly in parsing), or, exceptionally, in an array of single words, or, for source-defined kinds of value, in a standard Inform word range. The following routine parses an exceptional case. This all looks like a lot of fuss for not much gain, but is done so that the `Types.i6t` file can specify a multiple-word name for a type: note that the contents of said file are not in the source text, so can't have source text word numbers, which is why we can't specify the name in the usual way.

```
int recognise_type_template_variables = FALSE;
int data_type_parse_long_name(int w1, int w2) {
    data_type_id_rules *dtid;
    int i;
    LOOP_OVER(dtid, data_type_id_rules) {
        if (dtid->no_words_in_exotic_name == 0) continue;
        if (dtid->is_constructor) continue;
        if ((dtid->is_template_variable) &&
            (recognise_type_template_variables == FALSE)) continue;
        if ((w2-w1+1) != dtid->no_words_in_exotic_name) continue;
        for (i=0; i<dtid->no_words_in_exotic_name; i++) {
            if (lw_array[w1+i].lw_identity == dtid->words_in_exotic_name[i])
                continue;
            goto ContinueOuter;
        }
        return type_ID_with_this_dtid(dtid);
        ContinueOuter: ;
    }
    LOOP_OVER(dtid, data_type_id_rules) {
        if (dtid->no_words_in_exotic_plural == 0) continue;
        if (dtid->is_constructor) continue;
        if ((dtid->is_template_variable) &&
            (recognise_type_template_variables == FALSE)) continue;
        if ((w2-w1+1) != dtid->no_words_in_exotic_plural) continue;
        for (i=0; i<dtid->no_words_in_exotic_plural; i++) {
            if (lw_array[w1+i].lw_identity == dtid->words_in_exotic_plural[i])
                continue;
            goto ContinueOuterP;
        }
        return type_ID_with_this_dtid(dtid);
        ContinueOuterP: ;
    }
    return UNKNOWN;
}
```

The function data_type_parse_long_name is called from 7/kov.

§**42.** The S-parser needs the following, which looks at a word range and tries to find text making a kind construction: if it does, it returns the ID code for the constructor, and adjusts the word range to the kind being constructed on; if it fails, it returns `UNKNOWN`. For instance, given "list of marbles", it adjusts the word range to "marbles" and returns `LIST_OF_TY`.

```
int parse_constructor_name(int *w1, int *w2) {
    data_type_id_rules *dtid;
    int i;
    LOOP_OVER(dtid, data_type_id_rules) {
        if (dtid->is_constructor == FALSE) continue;
        if ((*w2-*w1+1) < dtid->no_words_in_exotic_name) continue;
        for (i=0; i<dtid->no_words_in_exotic_name; i++)
            if (lw_array[*w1+i].lw_identity != dtid->words_in_exotic_name[i])
                goto ContinueOuter;
        *w1 = *w1 + (dtid->no_words_in_exotic_name);
        return type_ID_with_this_dtid(dtid);
        ContinueOuter: ;
    }
    LOOP_OVER(dtid, data_type_id_rules) {
        if (dtid->is_constructor == FALSE) continue;
        if ((*w2-*w1+1) < dtid->no_words_in_exotic_plural) continue;
        for (i=0; i<dtid->no_words_in_exotic_plural; i++)
            if (lw_array[*w1+i].lw_identity != dtid->words_in_exotic_plural[i])
                goto ContinueOuterP;
        *w1 = *w1 + (dtid->no_words_in_exotic_plural);
        return type_ID_with_this_dtid(dtid);
        ContinueOuterP: ;
    }
    return UNKNOWN;
}
```

The function parse_constructor_name is called from 5/candd.

§**43.** And for the benefit of the index:

```
void data_type_print_long_name(OUTPUT_STREAM, int t) {
    int i;
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    for (i=0; i<dtid->no_words_in_exotic_name; i++) {
        if (i>0) WRITE(" ");
        WRITE("%s", vocab_get_exemplar(dtid->words_in_exotic_name[i], FALSE));
    }
}
void data_type_print_long_plural(OUTPUT_STREAM, int t) {
    int i;
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    for (i=0; i<dtid->no_words_in_exotic_plural; i++) {
        if (i>0) WRITE(" ");
        WRITE("%s", vocab_get_exemplar(dtid->words_in_exotic_plural[i], FALSE));
    }
}
```

The function data_type_print_long_name is called from 7/tids and 7/kix.

The function data_type_print_long_plural is called from 7/kix.

§**44.** And for the benefit of the data type interpreter:

```
void data_type_transcribe_name(char *buffer, data_type_id_rules *dtid, int lower_case) {
    buffer[0] = 0;
    int w1, w2;
    type_ID_copy_name(dtid->data_type_these_apply_to, &w1, &w2);
    if (w1 >= 0) {
        if (lower_case) print_raw_text_to_string(w1, w2, buffer);
        else print_text_to_string(w1, w2, buffer);
    } else {
        int l;
        if (type_ID_get_singular_parsing_name(dtid->data_type_these_apply_to)) {
            sprintf(buffer, "%s",
                vocab_get_exemplar(type_ID_get_singular_parsing_name(
                    dtid->data_type_these_apply_to), TRUE));
        } else
        for (l=0; l<dtid->no_words_in_exotic_name; l++) {
            sprintf(buffer+strlen(buffer), "%s ",
                vocab_get_exemplar(dtid->words_in_exotic_name[l], TRUE));
        }
    }
    if (dtid->is_constructor) sprintf(buffer+strlen(buffer), " value");
}
```

The function data_type_transcribe_name is called from 7/dti.

§**45. Questions about indexing.** For explanation, see the corresponding paragraphs of "Kinds of Value".

```
void data_type_set_specification_text(int t, char *desc) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    dtid->specification_text = desc;
}
char *data_type_get_specification_text(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->specification_text;
}
int data_type_get_index_priority(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->index_priority;
}
char *data_type_get_documentation_reference(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->documentation_reference;
}
int data_type_indexed_grey_if_empty(int t) {
    data_type_id_rules *dtid = type_ID_get_dtid(t);
    return dtid->indexed_grey_if_empty;
}
```

The function data_type_set_specification_text is called from 7/kov.
The function data_type_get_specification_text is called from 7/kov.
The function data_type_get_index_priority is called from 7/kix.
The function data_type_get_documentation_reference is called from 7/kix.
The function data_type_indexed_grey_if_empty is called from 7/kix.

Data Type Interpreter 7/dti

Purpose

To read in details of the built-in data types from the template file "Types.i6t", setting them up ready for use.

Template interpreter commands

```
22  {-callv:include_templates_for_types}
```

Definitions

¶1. Everyone loves a mini-language, so here is one. At the top level:

(a) Lines consisting of white space or whose first non-white space character is `!` are ignored as comments.

(b) A line ending with a colon `:` opens a new block. The text before the colon is the title of the block, except that the first character indicates its type:

(1) An asterisk means that the block is a template definition: for instance, `*PRINTING-ROUTINE:` says the block defines a template called `PRINTING-ROUTINE`. A template consists of Inform 7 source text which extends as far as the next `*END` line.

(2) A sharp sign `#` means that the block is a macro definition. For instance, `#UNIT:` says the block defines a template called `UNIT`. A macro is just a sequence of lines holding data type commands which continues to the beginning of the next block, or the end of the file.

(3) And otherwise the block is a type definition, but the optional opening character `+` marks the type as one which Inform requires the existence of. Thus `+NUMBER_TY:`, since Inform will crash if "Types.i6t" doesn't set this data type up, but `BOOJUMS_TY:` would validly declare a new data type called `BOOJUMS_TY` which isn't special to any of Inform's internals. The `+` signs are there as a help for hackers looking at "Types.i6t" and wondering what they can safely monkey with.

¶2. The body of a type definition is a sequence of one-line commands setting what properties the type has. These commands take the form of a name, a colon, and an operand; for instance,

```
i6-printing-routine-actions:DA_Number
used-in-let-with-cast-priority:10
can-be-type-of-global-variable:yes
```

As can be seen, the operands have different data types, and the possibilities are given here:

define `NO_TCA -1` *there's no operand*

define `BOOLEAN_TCA 1` *must be* `yes` *or* `no`

define `CCM_TCA 2` *a constant compilation method*

define `TEXT_TCA 3` *any text (no quotation marks or other delimiters are used)*

define `VOCABULARY_TCA 4` *any single word*

define `NUMERIC_TCA 5` *any decimal number*

define `TYPENAME_TCA 6` *any valid type number, such as* `NUMBER_TY`

define `TEMPLATE_TCA 7` *the name of a template whose definition is given in the file*

define `MACRO_TCA 8` *the name of a macro whose definition is given in the file*

¶3. When processing a command, we parse it into one of the following structures:

```
typedef struct single_type_command {
    struct type_command_definition *which_type_command;
    int boolean_argument;                                          where appropriate
    int numeric_argument;                                          where appropriate
    char *textual_argument;                                        where appropriate
    int ccm_argument;                                              where appropriate
    int no_vocabulary_arguments;                                   where appropriate
    struct vocabulary_entry *vocabulary_arguments[10];
    int domain_argument;                                           where appropriate
    int typename_argument;                                         where appropriate
    struct type_template_definition *template_argument;            where appropriate
    struct type_macro_definition *macro_argument;                  where appropriate
} single_type_command;
```

The structure single_type_command is private to this section.

¶4. A few of the commands connect pairs of data types together: for instance, when we write

```
cast:TEXT_ROUTINE_TY
```

in the definition block for TEXT_TY, we're saying that every text routine can always be cast implicitly to a text. There can be any number of these in the definition block, so we need somewhere to store details, and the following structure provides an entry in a linked list.

```
define CAST_SPECIFIC 1
define CAST_UNIVERSAL 2
define CAST_ASSIGNABLE 3
define CAST_ANY_WORD 4
define CAST_ANY_POINTER 5
```

```
typedef struct data_type_casting_rule {
    int cast_domain;                                          one of the above forms
    int single_value_casts;                                   when the form is CAST_SPECIFIC
    int casting_certainty;                                    ALWAYS_MATCH or only SOMETIMES_MATCH
    struct data_type_casting_rule *next_casting_rule;
} data_type_casting_rule;
```

The structure data_type_casting_rule is shared with 7/data.

¶5. And this is the analogous structure for giving I6 schemas to compare data of two different types:

```
typedef struct data_type_comparison_schema {
    int comparator;
    char *comparison_schema;
    struct data_type_comparison_schema *next_comparison_schema;
} data_type_comparison_schema;
```

The structure data_type_comparison_schema is shared with 7/data.

¶6. And, to cut to the chase, here is the complete table of commands:

```
type_command_definition table_of_type_commands[] = {
    { "block-data", block_data_TCC, BOOLEAN_TCA },
    { "can-be-type-of-global-variable", can_be_type_of_global_variable_TCC, BOOLEAN_TCA },
    { "can-coincide-with-property", can_coincide_with_property_TCC, BOOLEAN_TCA },
    { "can-exchange", can_exchange_TCC, BOOLEAN_TCA },
    { "defined-in-source-text", defined_in_source_text_TCC, BOOLEAN_TCA },
    { "has-i6-GPR", has_i6_GPR_TCC, BOOLEAN_TCA },
    { "has-native-constants", native_constants_TCC, BOOLEAN_TCA },
    { "indexed-grey-if-empty", indexed_grey_if_empty_TCC, BOOLEAN_TCA },
    { "is-a-unit", is_a_unit_TCC, BOOLEAN_TCA },
    { "is-an-enumeration", is_an_enumeration_TCC, BOOLEAN_TCA },
    { "is-constructor", is_constructor_TCC, BOOLEAN_TCA },
    { "is-incompletely-defined", is_incompletely_defined_TCC, BOOLEAN_TCA },
    { "is-template-variable", is_template_variable_TCC, BOOLEAN_TCA },
    { "multiple-block", multiple_block_TCC, BOOLEAN_TCA },
    { "named-values-created-with-assertions",
        named_values_created_with_assertions_TCC, BOOLEAN_TCA },
    { "quasinumerical", quasinumerical_TCC, BOOLEAN_TCA },
    { "unassignable", unassignable_TCC, BOOLEAN_TCA },
    { "used-in-let-without-casts", used_in_let_without_casts_TCC, BOOLEAN_TCA },
    { "uses-signed-comparisons", uses_signed_comparisons_TCC, BOOLEAN_TCA },

    { "apply-macro", apply_macro_TCC, MACRO_TCA },
    { NULL, -1, NO_TCA }
};
```

¶7. Where each legal command is defined with a block like so:

```
typedef struct type_command_definition {
    char *text_of_command;
    int opcode_number;
    int operand_type;
} type_command_definition;
```

The structure type_command_definition is private to this section.

¶8. Macros and templates have their definitions stored in structures thus:

```
typedef struct type_template_definition {
    char *template_name;                                  including the asterisk, e.g., "*PRINTING-ROUTINE"
    char *template_text;
    MEMORY_MANAGEMENT
} type_template_definition;

typedef struct type_macro_definition {
    char *type_macro_name;                                including the sharp, e.g., "#UNIT"
    int type_macro_line_count;
    struct single_type_command type_macro_line[MAX_TYPE_MACRO_LENGTH];
    MEMORY_MANAGEMENT
} type_macro_definition;
```

The structure type_template_definition is private to this section.
The structure type_macro_definition is private to this section.

¶9. And this makes a note to insert the relevant chunk of I7 source text later on. (We do this because type definitions are read very early on in Inform's run, whereas I7 source text can only be lexed later.)

```
typedef struct type_template_obligation {
    struct type_template_definition *remembered_template;        I7 source to insert...
    struct data_type_id_rules *remembered_dtid;                  ...concerning this data type
    MEMORY_MANAGEMENT
} type_template_obligation;
```

The structure type_template_obligation is private to this section.

¶10. Errors and limitations. In implementing the interpreter, we have to ask: who is it for? It occupies a strange position in being not quite for end users – the average Inform user will never know what the template is, let only how "Types.i6t" works – and yet not quite for internal use only, either. The main motivation for moving properties of data types out of Inform's program logic and into an external text file was to make it easier to verify that they were correctly described; but it was certainly also meant to give future Inform hackers – users who like to burrow into internals – scope for play.

The copy of "Types.i6t" supplied with Inform's standard distribution is, of course, correct. So how forgiving should we be, if errors are found in it? (These must result from mistakes by hackers.) To what extent should we allow arbitrarily complex constructions in "Types.i6t", as we would if it were a feature intended for end users?

We strike a sort of middle position. Inform will probably not crash if an incorrect "Types.i6t" is supplied, but it is free to throw internal errors or generate I6 code which fails to compile through I6. Inform will allow "Types.i6t" to be larger and more complex than the one supplied, but it is free to impose limits on this:

(a) The file can only be 32K long. (The standard distribution is about 20K.) Each line can be up to 1K long.
(b) The file must define 36 data types with fixed names (see below) which have relevance to the Inform internals, and is allowed to define up to 14 additional ones for use in the template layer. (In the standard distribution, it defines 8 of these extras.)
(c) The file can define any number of macros of up to 20 type commands each, but it must define at least the macros `#DEFAULTS`, `#NEW`, `#UNIT` and `#ENUMERATION`.
(d) The file can define any number of templates of I7 source text, with no restrictions (beyond that they have to fit into the file).

```
define MAX_TYPE_COMMAND_FILE_LENGTH 32768          the total length of "Types.i6t"
define MAX_DATA_TYPE_COMMAND_LENGTH 1024           length of any single line
define MAX_TYPE_MACRO_LENGTH 20                    maximum number of commands in any one macro
```

§1. Setting up the interpreter.

```
void data_type_initialise_type_interpreter(void) {
    initialise_type_text_archiver();
    initialise_let_casting_options();
    ⟨Assign source names to data types which are required to exist 2⟩;
}
```

The function data_type_initialise_type_interpreter is called from 7/tids.

§2. Here we assign textual names to correspond to internal NI source code constants, but it does not in itself create any types: all of that is done via type commands from the `Types.i6t` file, as fed into the type interpreter below. These are the ones marked with a `+` in the `Types.i6t` file.

```
define INFORM_KNOWS(name) type_ID_set_source_name(name, #name);
```

⟨Assign source names to data types which are required to exist 2⟩ ≡

```
    INFORM_KNOWS(ACTION_NAME_TY); INFORM_KNOWS(ACTIVITY_TY); INFORM_KNOWS(ANY_VALUE_TY);
    INFORM_KNOWS(ASSIGNABLE_VALUE_TY); INFORM_KNOWS(DESCRIPTION_OF_ACTION_TY);
    INFORM_KNOWS(EQUATION_TY); INFORM_KNOWS(EXTERNALFILE_TY); INFORM_KNOWS(FIGURENAME_TY);
    INFORM_KNOWS(OBJECT_DESCRIPTION_TY); INFORM_KNOWS(INDEXED_TEXT_TY);
    INFORM_KNOWS(INTERMEDIATE_TY);
    INFORM_KNOWS(KIND_OF_POINTER_VALUE_TY); INFORM_KNOWS(KIND_OF_WORD_VALUE_TY);
    INFORM_KNOWS(LIST_OF_TY); INFORM_KNOWS(NO_ENTRIES_TY); INFORM_KNOWS(NUMBER_TY);
    INFORM_KNOWS(OBJECT_TY); INFORM_KNOWS(PROPERTY_TY); INFORM_KNOWS(QUOT_TY);
    INFORM_KNOWS(RELATION_TY); INFORM_KNOWS(RULE_TY); INFORM_KNOWS(RULEBOOK_OUTCOME_TY);
    INFORM_KNOWS(RULEBOOK_TY); INFORM_KNOWS(SCENE_TY); INFORM_KNOWS(SNIPPET_TY);
    INFORM_KNOWS(SOUNDNAME_TY); INFORM_KNOWS(STORED_ACTION_TY);
    INFORM_KNOWS(TABLE_COLUMN_TY); INFORM_KNOWS(TABLE_TY); INFORM_KNOWS(TEST_ACTION_SPC);
    INFORM_KNOWS(TEXT_ROUTINE_TY); INFORM_KNOWS(TEXT_TY); INFORM_KNOWS(TIME_TY);
    INFORM_KNOWS(TRUTH_STATE_TY); INFORM_KNOWS(UNDERSTANDING_TY);
    INFORM_KNOWS(UNICODECHAR_TY); INFORM_KNOWS(USEOPTION_TY);
    INFORM_KNOWS(VALUE_DESCRIPTION_TY);
```

This code is used in §1.

§3. **The type command despatcher.** And this is where textual commands are received. (They come in from the template interpreter in Chapter 14; while they will almost always just be lines from "Types.i6t", they can in theory come from other template files as well.) Comments and blank lines have already been stripped out.

A template absorbs the raw text of its definition, and ends with `*END`; whereas a macro absorbs the parsed form of its commands, and continues to the next new heading. (Templates can't use the same end syntax because they often need to contain I7 phrase definitions, where lines end with colons.)

```
data_type_id_rules *current_dtid_described = NULL;
int total_type_command_lengths = 0;
void despatch_type_command(char *command) {
    ⟨Police the limits on type file and command length 4⟩;
    if (recording_a_type_template()) {
        if (strcmp(command, "*END") == 0) end_type_template();
        else record_into_type_template(command);
        return;
    }
    if (command[strlen(command)-1] == ':') {
```

```
        if (recording_a_type_macro()) end_type_macro();
        command[strlen(command)-1] = 0;                    remove the terminal colon
        ⟨Deal with the heading at the top of a type command block 5⟩;
        return;
    }
    single_type_command stc = parse_type_command(command);
    if (recording_a_type_macro()) record_into_type_macro(stc);
    else if (current_dtid_described) apply_type_command(stc, current_dtid_described);
    else internal_error("type command describes unspecified type");
}
```

The function despatch_type_command is called from 14/i6t.

§**4.**

⟨Police the limits on type file and command length 4⟩ ≡

```
    total_type_command_lengths += strlen(command) + 1;
    if (total_type_command_lengths >= MAX_TYPE_COMMAND_FILE_LENGTH)
        type_command_error(command, "too great an extent of type commands");
    if (strlen(command) >= MAX_DATA_TYPE_COMMAND_LENGTH)
        type_command_error(command, "type command too long");
```

This code is used in §3.

§**5.** The limit on the number of data types is reached when we collide with `BASE_OF_DATA_TYPE_IDS`. In practice we start at 50 and that's set to 100, which is why the limit comes out at 50.

⟨Deal with the heading at the top of a type command block 5⟩ ≡

```
    if (command[0] == '#') begin_type_macro(command);
    else if (command[0] == '*') begin_type_template(command);
    else if (command[0] == '+') {
        int x = type_ID_get_ID_for_source_name(command+1);
        if (x == UNKNOWN) internal_error("type command describes type with no known name");
        current_dtid_described = dtid_new(x);
    } else {
        int x = type_ID_get_ID_for_source_name(command);
        if (x != UNKNOWN) internal_error("type command describes already-known type");
        x = next_Types_dot_i6_number++;
        if (x >= BASE_OF_DATA_TYPE_IDS)
            internal_error("too many data types created by template commands");
        type_ID_set_source_name(x, archive_type_text(command));
        current_dtid_described = dtid_new(x);
    }
```

This code is used in §3.

§**6. Parsing single type commands.** Each command is read in as text, parsed and stored into a modest structure.

```
single_type_command parse_type_command(char *command) {
    char *argument = NULL;
    single_type_command stc;
    ⟨Parse line into command and argument, divided by a colon 8⟩;
    ⟨Initialise the STC to a blank command 7⟩;
    ⟨Identify the command being used 9⟩;
    switch(stc.which_type_command->operand_type) {
        case BOOLEAN_TCA: ⟨Parse a boolean argument for a type command 10⟩; break;
        case CCM_TCA: ⟨Parse a CCM argument for a type command 11⟩; break;
        case MACRO_TCA: ⟨Parse a macro name argument for a type command 17⟩; break;
        case NUMERIC_TCA: ⟨Parse a numeric argument for a type command 14⟩; break;
        case TEMPLATE_TCA: ⟨Parse a template name argument for a type command 16⟩; break;
        case TEXT_TCA: ⟨Parse a textual argument for a type command 12⟩; break;
        case TYPENAME_TCA: ⟨Parse a typename argument for a type command 15⟩; break;
        case VOCABULARY_TCA: ⟨Parse a vocabulary argument for a type command 13⟩; break;
    }
    return stc;
}
```

§**7.**

⟨Initialise the STC to a blank command 7⟩ ≡

```
stc.which_type_command = NULL;
stc.boolean_argument = NOT_APPLICABLE;
stc.numeric_argument = 0;
stc.textual_argument = NULL;
stc.ccm_argument = -1;
stc.no_vocabulary_arguments = 0;
stc.domain_argument = 0;
stc.typename_argument = UNKNOWN;
stc.macro_argument = NULL;
stc.template_argument = NULL;
```

This code is used in §6.

§**8.** Spaces and tabs after the colon are skipped; so a textual argument cannot begin with those characters, but that doesn't matter for the things we need.

⟨Parse line into command and argument, divided by a colon 8⟩ ≡

```
int i;
for (i=0; command[i]; i++)
    if (command[i] == ':') {
        command[i++]=0;
        while ((command[i] == ' ') || (command[i] == '\t')) i++;
        argument = command + i;
        break;
    }
if (argument == NULL) type_command_error(command, "type command without argument");
```

This code is used in §6.

§**9.** The following is clearly inefficient, but is not worth optimising. It makes about 20 calls to `strcmp` per command, and there are about 600 commands in a typical run of Inform, so the total cost is about 12,000 calls to `strcmp` with quite small strings as arguments – which is negligible for our purposes, so we neglect it.

⟨Identify the command being used 9⟩ ≡
```
int i;
for (i=0; table_of_type_commands[i].text_of_command; i++)
    if (strcmp(command, table_of_type_commands[i].text_of_command) == 0)
        stc.which_type_command = &(table_of_type_commands[i]);
if (stc.which_type_command == NULL) type_command_error(command, "no such type command");
```

This code is used in §6.

§**10.**

⟨Parse a boolean argument for a type command 10⟩ ≡
```
if (strcmp(argument, "yes") == 0) stc.boolean_argument = TRUE;
else if (strcmp(argument, "no") == 0) stc.boolean_argument = FALSE;
else type_command_error(command, "boolean type command takes yes/no argument");
```

This code is used in §6.

§**11.**

⟨Parse a CCM argument for a type command 11⟩ ≡
```
if (strcmp(argument, "none") == 0) stc.ccm_argument = NONE_CCM;
else if (strcmp(argument, "literal") == 0) stc.ccm_argument = LITERAL_CCM;
else if (strcmp(argument, "quantitative") == 0) stc.ccm_argument = QUANTITATIVE_CCM;
else if (strcmp(argument, "special") == 0) stc.ccm_argument = SPECIAL_CCM;
else type_command_error(command, "type command with unknown constant-compilation-method");
```

This code is used in §6.

§**12.**

⟨Parse a textual argument for a type command 12⟩ ≡
```
stc.textual_argument = archive_type_text(argument);
```

This code is used in §6.

§13.

⟨Parse a vocabulary argument for a type command 13⟩ ≡

```
char *latest_word;
int i;
stc.no_vocabulary_arguments = 0;
argument = archive_type_text(argument);
latest_word = argument;
for (i=0; argument[i]; i++)
    if (argument[i] == ' ') {
        argument[i++] = 0;
        stc.vocabulary_arguments[stc.no_vocabulary_arguments++]
            = vocab_entry_for_text(latest_word);
        latest_word = argument+i;
    }
stc.vocabulary_arguments[stc.no_vocabulary_arguments++] =
    vocab_entry_for_text(latest_word);
if (stc.no_vocabulary_arguments > MAX_WORDS_IN_TYPE_NAME) {
    type_command_error(command, "too many words in type command");
    stc.no_vocabulary_arguments = MAX_WORDS_IN_TYPE_NAME;
}
```

This code is used in §6.

§14.

⟨Parse a numeric argument for a type command 14⟩ ≡

```
stc.numeric_argument = atoi(argument);
```

This code is used in §6.

§15.

⟨Parse a typename argument for a type command 15⟩ ≡

```
int i;
for (i=0; argument[i]; i++)
    if ((argument[i] == '>') && (argument[i+1] == '>') && (argument[i+2] == '>')) {
        argument[i] = 0;
        stc.textual_argument = archive_type_text(argument+i+3);
        break;
    }
stc.typename_argument = UNKNOWN;
stc.domain_argument = CAST_SPECIFIC;
if (strcmp(argument, "<all>") == 0) stc.domain_argument = CAST_UNIVERSAL;
if (strcmp(argument, "<assignable>") == 0) stc.domain_argument = CAST_ASSIGNABLE;
if (strcmp(argument, "<word>") == 0) stc.domain_argument = CAST_ANY_WORD;
if (strcmp(argument, "<pointer>") == 0) stc.domain_argument = CAST_ANY_POINTER;
if (stc.domain_argument == CAST_SPECIFIC) {
    stc.typename_argument = type_ID_get_ID_for_source_name(argument);
    if (stc.typename_argument == UNKNOWN)
        type_command_error(command, "unknown type name in type command");
}
```

This code is used in §6.

§**16.**

⟨Parse a template name argument for a type command 16⟩ ≡

```
stc.template_argument = parse_type_template_name(argument);
if (stc.template_argument == NULL)
    type_command_error(command, "unknown template name in type command");
```

This code is used in §6.

§**17.**

⟨Parse a macro name argument for a type command 17⟩ ≡

```
stc.macro_argument = parse_type_macro_name(argument);
if (stc.macro_argument == NULL)
    type_command_error(command, "unknown template name in type command");
```

This code is used in §6.

§**18. Source text templates.** These are passages of I7 source text which can be inserted into the main source text at the request of any data type. An example would be:

```
*UNDERSTOOD-VARIABLE:
<type> understood is a <type> which varies.
*END
```

The template `*UNDERSTOOD-VARIABLE` contains only a single sentence of source text, and the idea is to make a new global variable associated with a given data type. Note that the text is not quite literal, because it can contain wildcards like `<type>`, which expands to the name of the kind of value in question: for instance, we might get

number understood is a number which varies.

There are a few limitations on what template text can include. Firstly, nothing with angle brackets in, except where a wildcard appears. Secondly, each sentence must end at the end of a line, and similarly the colon for any rule or other definition. Thus this template would fail:

```
*UNDERSTOOD-VARIABLE:
<type> understood is a <type> which
varies. To judge <type>: say "I judge [<type> understood]."
*END
```

because the first sentence ends in the middle of the second line, and the colon dividing the phrase header from its definition is also mid-line. The template must be reformatted thus to work:

```
*UNDERSTOOD-VARIABLE:
<type> understood is a <type> which varies.
To judge <type>:
    say "I judge [<type> understood]."
*END
```

§**19.** So, to begin:

```
type_template_definition *new_type_template(char *name) {
    type_template_definition *ttd = CREATE(type_template_definition);
    ttd->template_name = archive_type_text(name);
    return ttd;
}
type_template_definition *parse_type_template_name(char *name) {
    type_template_definition *ttd;
    LOOP_OVER(ttd, type_template_definition)
        if (strcmp(name, ttd->template_name) == 0) return ttd;
    return NULL;
}
```

§**20.** Here is the code which records templates, reading them as one line of plain text at a time. (In the above example, `record_into_type_template` would be called just once, with the single source text line.)

```
type_template_definition *current_type_template = NULL;                    the one now being recorded
int recording_a_type_template(void) {
    if (current_type_template) return TRUE;
    return FALSE;
}
void begin_type_template(char *name) {
    if (current_type_template) internal_error("first stt still recording");
    if (parse_type_template_name(name))
        internal_error("duplicate definition of source text template");
    current_type_template = new_type_template(name);
    current_type_template->template_text = begin_recording_type_text();
}
void record_into_type_template(char *line) {
    record_type_text(line);
}
void end_type_template(void) {
    if (current_type_template == NULL) internal_error("no stt currently recording");
    end_recording_type_text();
    current_type_template = NULL;
}
```

§**21.** So much for recording a template. To "play back", we need to take its text and squeeze it into the main source text, but there's a timing issue: when we read type commands it is very early in Inform's run, and the lexer may not even have started yet. So we simply remember our intention to insert the text:

```
void remember_to_transcribe_spec_template(type_template_definition *ttd, data_type_id_rules *dt) {
    type_template_obligation *tto = CREATE(type_template_obligation);
    tto->remembered_template = ttd;
    tto->remembered_dtid = dt;
}
```

§**22.** ...until now, when it's later on and the source text does indeed exist.

```
void include_templates_for_types(void) {
    type_template_obligation *tto;
    LOOP_OVER(tto, type_template_obligation)
        transcribe_type_template(tto->remembered_template, tto->remembered_dtid);
}
void transcribe_type_template(type_template_definition *ttd, data_type_id_rules *dtid) {
    if (ttd == NULL) internal_error("tried to transcribe missing source text template");
    char *p = ttd->template_text;
    int i = 0;
    while (p[i]) {
        char template_line_buffer[MAX_DATA_TYPE_COMMAND_LENGTH], terminator = 0;
        if ((p[i] == '\n') || (p[i] == ' ')) { i++; continue; }
        ⟨Transcribe one line of the template into the line buffer 23⟩;
        if (template_line_buffer[0]) {
            int x1 = lexer_wordcount, x2;
            feed_into_lexer(template_line_buffer, FALSE, FALSE);
            x2 = lexer_wordcount-1;
            if (terminator != 0) make_sentence_node(x1, x2, terminator);
        }
    }
    register_recently_lexed_phrases();
}
```

The function include_templates_for_types is invoked by a command in a `.i6t` template file.

§**23.** Inside template text, anything in angle brackets `<...>` is a wildcard. These cannot be nested and cannot include newlines. All other material is copied verbatim into the line buffer.

The only sentence terminators we recognise are full stop and colon; in particular we wouldn't recognise a stop inside quoted matter. This does not matter, since such things never come into type definitions.

⟨Transcribe one line of the template into the line buffer 23⟩ ≡

```
    int j=0;
    while ((p[i] != 0) && (p[i] != '\n')) {
        if (p[i] == '<') {
            char template_wildcard_buffer[MAX_DATA_TYPE_COMMAND_LENGTH];
            int k=0;
            i++;
            while ((p[i] != 0) && (p[i] != '\n') && (p[i] != '>'))
                template_wildcard_buffer[k++] = p[i++];
            template_wildcard_buffer[k++] = 0;
            i++;
            ⟨Transcribe the template wildcard 24⟩;
        } else template_line_buffer[j++] = p[i++];
    }
    template_line_buffer[j] = 0;
    if ((j>0) && ((template_line_buffer[j-1] == '.') || (template_line_buffer[j-1] == ':'))) {
        terminator = template_line_buffer[j-1];
        template_line_buffer[j-1] = 0;
    }
```

This code is used in §22.

§**24.** Only four wildcards are recognised:

⟨Transcribe the template wildcard 24⟩ ≡
```
if (strcmp(template_wildcard_buffer, "type") == 0)
    ⟨Transcribe the data type's name 25⟩
else if (strcmp(template_wildcard_buffer, "lower-case-type") == 0)
    ⟨Transcribe the data type's name in lower case 26⟩
else if (strcmp(template_wildcard_buffer, "type-number") == 0)
    ⟨Transcribe the data type's number 27⟩
else if (strcmp(template_wildcard_buffer, "printing-routine") == 0)
    ⟨Transcribe the data type's I6 printing routine 28⟩
else internal_error("no such source text template wildcard");
j = strlen(template_line_buffer);
```

This code is used in §23.

§**25.**

⟨Transcribe the data type's name 25⟩ ≡
```
data_type_transcribe_name(template_line_buffer+j, dtid, FALSE);
```

This code is used in §24.

§**26.**

⟨Transcribe the data type's name in lower case 26⟩ ≡
```
data_type_transcribe_name(template_line_buffer+j, dtid, TRUE);
```

This code is used in §24.

§**27.**

⟨Transcribe the data type's number 27⟩ ≡
```
sprintf(template_line_buffer+j, "%d", dtid->data_type_these_apply_to);
```

This code is used in §24.

§**28.**

⟨Transcribe the data type's I6 printing routine 28⟩ ≡
```
sprintf(template_line_buffer+j, "%s", dtid->dt_I6_identifier);
```

This code is used in §24.

§**29. Type macros.** These are much simpler, and are just lists of type commands grouped together under names.

```
type_macro_definition *current_type_macro = NULL;                    the one now being recorded
type_macro_definition *new_type_macro(char *name) {
    type_macro_definition *tmd = CREATE(type_macro_definition);
    tmd->type_macro_line_count = 0;
    tmd->type_macro_name = archive_type_text(name);
    return tmd;
}
type_macro_definition *parse_type_macro_name(char *name) {
    type_macro_definition *tmd;
    LOOP_OVER(tmd, type_macro_definition)
        if (strcmp(name, tmd->type_macro_name) == 0) return tmd;
    return NULL;
}
```

The function parse_type_macro_name is called from 7/data.

§**30.** And here once again is the code to record macros:

```
int recording_a_type_macro(void) {
    if (current_type_macro) return TRUE;
    return FALSE;
}
void begin_type_macro(char *name) {
    if (parse_type_macro_name(name))
        internal_error("duplicate definition of type command macro");
    current_type_macro = new_type_macro(name);
}
void record_into_type_macro(single_type_command stc) {
    if (current_type_macro == NULL)
        internal_error("type macro not being recorded");
    if (current_type_macro->type_macro_line_count >= MAX_TYPE_MACRO_LENGTH)
        internal_error("type macro contains too many lines");
    current_type_macro->type_macro_line[current_type_macro->type_macro_line_count++] = stc;
}
void end_type_macro(void) {
    if (current_type_macro == NULL) internal_error("ended type macro outside one");
    current_type_macro = NULL;
}
```

§**31.** Playing back is easier, since it's just a matter of despatching the stored commands in sequence to the relevant data type.

```
void play_back_type_macro(type_macro_definition *macro, data_type_id_rules *dtid) {
    int i;
    if (macro == NULL) internal_error("no such type macro to play back");
    for (i=0; i<macro->type_macro_line_count; i++)
        apply_type_command(macro->type_macro_line[i], dtid);
}
```

The function play_back_type_macro is called from 7/data.

§32. The type text archiver. Large chunks of the text in "Types.i6t" will need to exist permanently in memory, and this is where we make room for them. We can either archive a single C string, or go into recording mode and accept a series of them, concatenated with newlines dividing them. The worst-case storage requirement is that we need to store the entire file, so that's how much memory we put aside.

```
char archive_for_data_type_text[MAX_TYPE_COMMAND_FILE_LENGTH];                    text storage area
char *top_of_afdtt = archive_for_data_type_text;                                  next free character
int afdtt_recording_mode = FALSE;

void initialise_type_text_archiver(void) {
    archive_for_data_type_text[0] = 0;
}

char *archive_type_text(char *original) {
    if (afdtt_recording_mode) internal_error("can't archive while recording");
    char *new_location = top_of_afdtt;
    top_of_afdtt = top_of_afdtt + strlen(original) + 1;
    strcpy(new_location, original);
    return new_location;
}
```

§**33.** And here is recording mode:

```
char *begin_recording_type_text(void) {
    top_of_afdtt[0] = 0;
    afdtt_recording_mode = TRUE;
    return top_of_afdtt;
}

void record_type_text(char *line) {
    if (afdtt_recording_mode == FALSE) internal_error("can't record outside recording");
    sprintf(top_of_afdtt + strlen(top_of_afdtt), "%s\n", line);
}

void end_recording_type_text(void) {
    top_of_afdtt = top_of_afdtt + strlen(top_of_afdtt) + 1;
    afdtt_recording_mode = FALSE;
}
```

§34. Error messages.

```
void type_command_error(char *command, char *error) {
    LOG("Command error found at: %s\n", command);
    internal_error(error);
}
```

§**35. Applying type commands.** We take a single type command and apply it to a given data type.

        return;
}
```

This code is used in §35.

§**40.** And that completes the data type interpreter.

Dimensions 7/dim

Purpose

To keep a small database indicating the physical dimensions of numerical values, and how they combine: for instance, allowing us to specify that a length times a length is an area.

Definitions

¶1. Dimension in this sense is a term drawn from physics. The idea is that when quantities are multiplied together, their natures are combined as well as the actual numbers involved. For instance, in

$$v = f\lambda$$

if the frequency f of a wave is measured in Hz (counts per second), and the wavelength λ in m, then the velocity v must be measured in m/s: and that is indeed a measure of velocity, so this looks right. We can tell that the formula

$$v = f^2\lambda$$

must be wrong because it would result in an acceleration. Physicists use the term "dimensions" much as Inform uses the term "kinds of value".

Inform applies dimension-checking to all "quasinumerical" KOVs – those which can be expressed numerically. The choice of which KOVs are quasinumerical is all done in "Types.i6t", not built into Inform at the compiler level, but the standard setup makes number, time, intermediate results of calculations (see below), and what the Inform documentation calls "units" – kinds of value specified by literal patterns.

¶2. Inform divides quasinumerical KOVs into three: base units, derived units with dimensions, and dimensionless units. In the default setup provided by "Types.i6t", a typical run has one base unit ("time"), one dimensionless unit ("number") and – unless the source text does something very strange – no derived units.

It would no doubt be cool to distinguish these by applying Buckingham's π-theorem to all the equations we need to use, but this is a tricky technique and does not always produce the "natural" results which people expect. Instead, Inform requires the writer to specify explicitly how units combine.

Number and time are built-in special cases. Further base units are created every time source text like this is read:

> Mass is a kind of value. 1kg specifies a mass.

Derived units only come about when the source text specifies a multiplication rule. For instance, when Inform reads

> A mass times an acceleration specifies a force.

it chooses one of the three units – say, force – and derives that from the others.

Multiplication rules are stored in a linked list associated with left operand; so that the rule A times B specifies C causes (B, C) to be stored in the list of `multiplications` belonging to A.

```
typedef struct dimensional_rules {
    struct dimensional_rule *multiplications;
} dimensional_rules;
typedef struct dimensional_rule {
    int word_ref1, word_ref2;
    int right;
    int outcome;
    struct dimensional_rule *next;
} dimensional_rule;
```

The structure dimensional_rules is private to this section.
The structure dimensional_rule is private to this section.

¶3. The derivation process can be seen in action by feeding Inform definitions of the SI units (see the test case `SIUnits-G`) and looking at the output of:

Test dimensions (internal) with –.

(The dash is meaningless – this is a test with no input.) In the output, we see that

```
Base units: time, length, mass, elapsed time, electric current, temperature, luminosity
Derived units:
frequency = (elapsed time)-1
force = (length).(mass).(elapsed time)-2
energy = (length)2.(mass).(elapsed time)-2
pressure = (length)-1.(mass).(elapsed time)-2
power = (length)2.(mass).(elapsed time)-3
electric charge = (elapsed time).(electric current)
voltage = (length)2.(mass).(elapsed time)-3.(electric current)-1
```

...and so on. Those expressions on the right hand sides are "derived units", where the numbers are powers, so that negative numbers mean division. It's easy to see why we want to give names and notations for some of these derived units – imagine going into a cycle shop and asking for a $5\mathrm{m}^2 \cdot \mathrm{kg} \cdot \mathrm{s}^{-3} \cdot \mathrm{A}^{-1}$ battery.

¶4. A "dimensionless" quantity is one which is just a number, and is not a physical measurement as such. In an equation like

$$K = \frac{mv^2}{2}$$

the 2 is clearly dimensionless, but other possibilities also exist. The arc length of part of a circle at radius r drawn out to angle θ (if measured in radians) is given by:

$$A = \theta r$$

Here A and r are both lengths, so the angle θ must be dimensionless. But clearly it's not quite conceptually the same thing as an ordinary number. Inform creates new dimensionless quantities this way, too:

Angle is a kind of value. 1 rad specifies an angle. Length times angle specifies a length.

Inform is not quite so careful about distinguishing dimensionless quantities as some physicists might be. The official SI units distinguish angle, measured in radians, and solid angle, in steradians, writing them as having units $\mathrm{m} \cdot \mathrm{m}^{-1}$ and $\mathrm{m}^2 \cdot \mathrm{m}^{-2}$ respectively – one is a ratio of lengths, the other of areas. Inform cancels the units and sees them as dimensionally equal. So if we write:

Solid angle is a kind of value. 1 srad specifies an solid angle. Area times solid angle specifies an area.

then Inform treats angle and solid angle as having the same multiplicative properties – but it still allows variables to have either one as a kind of value, and prints them differently.

Note that a dimensionless unit (other than `NUMBER_TY`) can only get that way by derivation, so it is always a derived unit, never a base unit.

¶5. In the process of calculations, we often need to create other and nameless units as partial answers of calculations. Consider the kinetic energy equation

$$K = \frac{mv^2}{2}$$

being evaluated the way a computer does it, one step at a time. One way takes the mass, multiplies by the velocity to get a momentum, multiplies by the velocity again to get energy, then divides by a dimensionless constant. But another way would be to square the velocity first, then multiply by mass to get energy, then halve. If we do it that way, what units are the squared velocity in? The answer has to be

```
(length)2.(elapsed time)-2
```

but that's a unit which isn't useful for much, and doesn't have any everyday name. Inform creates what are called "intermediate KOVs" like this in order to be able to represent the kinds of intermediate values which turn up in calculation. They use the atomic KOV number `INTERMEDIATE_TY`, they are nameless, and the user isn't allowed to store the results permanently. (They can't be the KOV of a global variable, a table column, and so on.) If the user wants to deal with such values on a long-term basis, he must give them a name, like this:

```
Funkiness is a kind of value. 1 Claude is a funkiness. A velocity times a velocity specifies a funkiness.
```

¶6. Expressions like $\mathrm{m}^2 \cdot \mathrm{kg}$ are stored inside Inform as sequences of ordered pairs in the form

$$((B_1, p_1), (B_2, p_2), ..., (B_k, p_k))$$

where each B_i is the type ID of a base unit, each p_i is a non-zero integer, and $B_1 < B_2 < ... < B_k$. For instance, energy would be

$$((\text{length}, 2), (\text{mass}, 1), (\text{elapsed time}, -2)).$$

Every physically different derived unit has a unique and distinct sequence. This is only true because a unit sequence is forbidden to contain derived units. For instance, specific heat capacity looks as if it is written with two different units in physics:

$$\mathrm{J} \cdot \mathrm{K}^{-1} \cdot \mathrm{kg}^{-1} \quad = \quad \mathrm{m}^2 \cdot \mathrm{s}^{-2} \cdot \mathrm{K}^{-1}$$

But this is because the Joule is a derived unit. Substituting $\mathrm{J} = \mathrm{m}^2 \cdot \mathrm{kg} \cdot \mathrm{s}^{-2}$ to get back to base units shows that both sides would be computed as the same unit sequence.

The case $k = 0$, the empty sequence, is not only legal but important: it is the derivation for a dimensionless unit. (As discussed above, Inform doesn't see different dimensionless units as being physically different.)

```
typedef struct unit_pair {
    int base_unit;                                   a type ID number
    int power;                                       a non-zero integer
} unit_pair;
```

The structure unit_pair is private to this section.

¶7. The following is a hard limit, but really not a problematic one. The entire SI system has only 7 base units, and the only named scientific unit I've seen which has even 5 terms in its derivation is molar entropy, a less than everyday chemical measure ($\mathrm{kg} \cdot \mathrm{m}^2 \cdot \mathrm{s}^{-2} \cdot \mathrm{K}^{-1} \cdot \mathrm{mol}^{-1}$, if you're taking notes).

```
define MAX_BASE_UNITS_IN_SEQUENCE 16

typedef struct unit_sequence {
    int no_unit_pairs;                                    in range 0 to MAX_BASE_UNITS_IN_SEQUENCE
    struct unit_pair unit_pairs[MAX_BASE_UNITS_IN_SEQUENCE];
    int scaling_factor;                                   see discussion of scaling below
} unit_sequence;
```

The structure unit_sequence is shared with 7/dim.

¶8. Manipulating units like $\mathrm{m}^2 \cdot \mathrm{kg} \cdot \mathrm{s}^{-2}$ looks a little like manipulating formal polynomials in several variables, and of course that isn't an accident. Another way of thinking of the above is that we have a ring R of underlying numbers but that all arithmetic is done in a larger ring. For each unit extend by R by a pair of formal variables U_i and U_i^{-1}, and then quotient by the ideal generated by $U_j U_j^{-1}$ (so that they are indeed reciprocals of each other, as the notation suggests) and also by all of the derivations we know of. Thus Inform calculates in the ring:

$$I = R[U_1, U_2, ..., U_n, U_1^{-1}, ..., U_n^{-1}]/(U_1U_1^{-1}, U_2U_2^{-1}, ..., U_nU_n^{-1}, D_1, D_2, ..., D_i).$$

It does that in practice by eliminating all of the U_i and U_i^{-1} which are derived, so that it's left with just

$$I = R[U_1, U_2, ..., U_k, U_1^{-1}, ..., U_k^{-1}]/(U_1U_1^{-1}, U_2U_2^{-1}, ..., U_kU_k^{-1}).$$

For instance, given seconds, Watts and Joules,

$$I = R[\mathrm{s}, \mathrm{s}^{-1}, \mathrm{W}, \mathrm{W}^{-1}, \mathrm{J}, \mathrm{J}^{-1}]/(\mathrm{ss}^{-1} = 1, \mathrm{WW}^{-1} = 1, \mathrm{JJ}^{-1} = 1, \mathrm{sW} = \mathrm{J})$$

which by substituting all occurrences of J can be reduced to:

$$I = R[\mathrm{s}, \mathrm{s}^{-1}, \mathrm{W}, \mathrm{W}^{-1}]/(\mathrm{ss}^{-1} = 1, \mathrm{WW}^{-1} = 1).$$

Of course there are other ways to calculate I – we could have eliminated any of the three units and kept the other two.

If the derivations were ever more complex than $AB = C$, we might have to use some elegant algorithms for calculating Gröbner bases in order to determine I. But Inform's syntax is such that the writer of the source text gives us the simplest possible description of the ideal, so no such fun occurs.

What does this ring look like? Because we are not allowed to add terms with different powers of the variables, we only ever deal with monomials. Thus we can form $2\mathrm{Ws}^{-1} + 7\mathrm{Ws}^{-1}$, but Inform forbids us to form (say) $6\mathrm{J} + 7\mathrm{W}$. We can therefore picture the ring I as a great mass of parallel copies of R. Dimensionless values all live in R itself, while energies all live in R.s.W, powers in R.W and so on. Addition and subtraction slide values around within their own parallel copies, but multiplication and division move them from one to another. The computation $v_1 v_2$ is done in general by calculating the numerical part (in R) at run-time, and the units (the choice of which copy of R) at compile-time.

¶9. But enough abstraction: time for some arithmetic. Inform performs checking whenever values from two different KOVS are combined by any of eight arithmetic operations, numbered as follows. The numbers must *not* be changed without amending the definitions of "plus" and so on in the Standard Rules.

```
define NO_OPERATIONS 8
define PLUS_OPERATION 0                    addition
define MINUS_OPERATION 1                   subtraction
define TIMES_OPERATION 2                   multiplication
define DIVIDE_OPERATION 3                  division
define REMAINDER_OPERATION 4               remainder after division
define APPROXIMATION_OPERATION 5           "X to the nearest Y"
define ROOT_OPERATION 6                    square root – a unary operation
define CUBEROOT_OPERATION 7                cube root – similarly unary
define EQUALS_OPERATION 8                  set equal – used only in equations
define POWER_OPERATION 9                   raise to integer power – used only in equations
define UNARY_MINUS_OPERATION 10            unary minus – used only in equations
```

¶10. The following is associated with "total...", as in "the total weight of things on the table", but that's a dodge used in the Standard Rules, and for dimensional purposes we ignore it.

```
define TOTAL_OPERATION 11                  not really one of the above
```

¶11. There are two reasons why Inform monitors arithmetic: to keep track of how it changes KOVs, and to preserve scaling factors.

We start from the principle that not every arithmetic operation can be done, and that even when it can, the result may have a different KOV than the operand(s) had. For one thing, every arithmetic operation requires that its operands are quasinumerical – Inform won't allow a text to be multiplied by a sound effect. (Occasionally we have thought about allowing text to be duplicated by multiplication – 2 times "zig" would be "zigzig", and maybe similarly for lists – but it always seemed a pose, fleetingly cool but seldom useful, and more likely to be used by mistake than intentionally.)

Other restrictions are also applied. For instance, a time cannot be added to a number, or vice versa; addition, subtraction and approximation require both operands to have the same units.

¶12. Finally, scaling. `NUMBER_TY` is straightforwardly an integer data type: it holds whole numbers. But other quasinumerical data types can be stored using scaled, fixed-point arithmetic. In general for each named unit U (base or derived) there is a positive integer k_U such that the true value v is stored at run-time as the I6 integer $k_U v$. We call this the scaled value.

For example, if the text reads:

```
Force is a kind of value. 1N specifies a force scaled up by 1000.
```

then $k = 1000$ and the value 1N will be stored at run-time as `1000`; forces can thus be calculated to a true value accuracy of at best 0.001N, stored at run-time as `1`.

It must be emphasised that this is scaled, fixed-point arithmetic: there are no mantissas or exponents. In such schemes the scale factor is usually 2^{16} or some similar power of 2, but here we want to use exactly the scale factors laid out by the source text – partly because the user knows best, partly so that it is unambiguous how to print values, partly so that source text like "0.001N" determines an exact value rather than being approximated by a binary equivalent.

§**1. Multiplication lists.** The linked lists of multiplication rules begin empty for every data type:

```
void dim_initialise(dimensional_rules *dimrs) {
    dimrs->multiplications = NULL;
}
```

The function dim_initialise is called from 7/data.

§**2.** And this adds a new one to the relevant list:

```
void record_multiplication_rule(int left, int right, int outcome) {
    dimensional_rules *dimrs = dtid_get_dim_rules(left);
    dimensional_rule *dimr;
    for (dimr = dimrs->multiplications; dimr; dimr = dimr->next)
        if (dimr->right == right) {
            sentence_problem(_P_(C7DimensionRedundant),
                "multiplication rules can only be given once",
                "and this combination is already established.");
            return;
        }
    dimensional_rule *dimr_new = CREATE(dimensional_rule);
    dimr_new->right = right;
    dimr_new->outcome = outcome;
    dimr_new->word_ref1 = -1; dimr_new->word_ref2 = -1;
    if (current_sentence) {
        dimr_new->word_ref1 = current_sentence->word_ref1;
        dimr_new->word_ref2 = current_sentence->word_ref2;
    }
    dimr_new->next = dimrs->multiplications;
    dimrs->multiplications = dimr_new;
}
```

§**3.** The following loop-header macro iterates through the possible triples (L, R, O) of multiplication rules $L \times R = O$.

```
define LOOP_OVER_MULTIPLICATIONS(left_operand, right_operand, outcome_type, wn)
    dimensional_rules *dimrs;
    dimensional_rule *dimr;
    LOOP_OVER_POSSIBLE_TYPE_IDS(left_operand)
        for (dimrs = dtid_get_dim_rules(left_operand),
            dimr = (dimrs)?(dimrs->multiplications):NULL,
            wn = (dimr)?(dimr->word_ref1):-1,
            right_operand = (dimr)?(dimr->right):0,
            outcome_type = (dimr)?(dimr->outcome):0;
            dimr;
            dimr = dimr->next,
            wn = (dimr)?(dimr->word_ref1):-1,
            right_operand = (dimr)?(dimr->right):0,
            outcome_type = (dimr)?(dimr->outcome):0)
```

§4. And this is where the user asks for a multiplication to come out in a particular way:

```
void dim_set_multiplication(kind_of_value *left, kind_of_value *right,
    kind_of_value *outcome) {
    if ((is_kovcon(left)) || (is_kovcon(right)) || (is_kovcon(outcome))) {
        sentence_problem(_P_(C7DimensionNotBaseKOV),
            "multiplication rules can only involve simple kinds of value",
            "rather than complicated ones such as lists of other values.");
        return;
    }
    if ((kov_quasinumerical(left) == FALSE) ||
        (kov_quasinumerical(right) == FALSE) ||
        (kov_quasinumerical(outcome) == FALSE)) {
        sentence_problem(_P_(C7NonDimensional),
            "multiplication rules can only be given between kinds of "
            "value which are known to be numerical",
            "and not all of these are. Saying something like 'Pressure is a "
            "kind of value.' is not enough - you may think 'pressure' ought "
            "to be numerical, but Inform doesn't know that yet. You need "
            "to add something like '100 Pa specifies a pressure.' before "
            "Inform will realise.");
        return;
    }
    int left_adt = kov_get_dimensional_data_type(left);
    int right_adt = kov_get_dimensional_data_type(right);
    int outcome_adt = kov_get_dimensional_data_type(outcome);
    record_multiplication_rule(left_adt, right_adt, outcome_adt);
    if ((left_adt == outcome_adt) && (right_adt == NUMBER_TY)) return;
    if ((right_adt == outcome_adt) && (left_adt == NUMBER_TY)) return;
    make_unit_derivation(left_adt, right_adt, outcome_adt);
}
```

The function dim_set_multiplication is called from 5/litp.

§5. **Unary operations.** All we need to know is which ones are unary, in fact, and:

```
int arithmetic_op_is_unary(int op) {
    switch (op) {
        case CUBEROOT_OPERATION:
        case ROOT_OPERATION:
        case UNARY_MINUS_OPERATION:
            return TRUE;
    }
    return FALSE;
}
```

The function arithmetic_op_is_unary is called from 7/tc and 10/eqns.

§**6. Euclid's algorithm.** In my entire life, I believe this is the only time I have ever actually used Euclid's algorithm for the GCD of two natural numbers. I've never quite understood why textbooks take this as somehow the typical algorithm. My maths students always find it a little oblique, despite the almost trivial proof that it works. I find it hard to visualise myself, for that matter. And then, consider that the average number of iterations τ_n, in effect its running time, is known to be

$$\tau_n = \frac{12 \log 2}{\pi^2} \log n + (4P + 5/2) + O(n^{-\frac{1}{6}+\epsilon})$$

for any $\epsilon > 0$, where P is defined in terms of an integral, Euler's constant, and an evaluation of the derivative of the Riemann zeta function – see D. E. Knuth, 'Evaluation of Porter's Constant', reprinted in *Selected Papers on Analysis of Algorithms* (Stanford: CSLI Lecture Notes 102, 2000). In practice, a shade under $\log n$ steps, then, which is nicely quick. But I don't look at the code and immediately see this, myself.

```
int gcd(int m, int n) {
    if ((m<1) || (n<1)) internal_error("applied gcd outside natural numbers");
    while (TRUE) {
        int rem = m%n;
        if (rem == 0) return n;
        m = n; n = rem;
    }
}
```

The function gcd is called from 5/litp.

§**7.** The sequence of operation here is to reduce the risk of integer overflows when multiplying `m` by `n`.

```
int lcm(int m, int n) {
    return (m/gcd(m, n))*n;
}
```

§**8. Unit sequences.** Given a base type B, convert it to a unit sequence: $B = B^1$, so we get a sequence with a single pair: $((B, 1))$. Uniquely, `NUMBER_TY` is born derived and dimensionless, though, so that comes out as the empty sequence.

```
unit_sequence data_spec_to_unit_sequence(int t) {
    unit_sequence us;
    if (t == NUMBER_TY) {
        us.no_unit_pairs = 0;
        us.unit_pairs[0].base_unit = 0; us.unit_pairs[0].power = 0;     redundant, but appeases gcc -O2
    } else {
        us.no_unit_pairs = 1;
        us.unit_pairs[0].base_unit = t; us.unit_pairs[0].power = 1;
    }
    return us;
}
```

The function data_spec_to_unit_sequence is called from 7/data.

§**9.** As noted above, two units represent dimensionally equivalent physical quantities if and only if they are identical, which makes comparison easy:

```
int compare_unit_sequences(unit_sequence *ik1, unit_sequence *ik2) {
    int i;
    if (ik1 == ik2) return TRUE;
    if ((ik1 == NULL) || (ik2 == NULL)) return FALSE;
    if (ik1->no_unit_pairs != ik2->no_unit_pairs) return FALSE;
    for (i=0; i<ik1->no_unit_pairs; i++)
        if ((ik1->unit_pairs[i].base_unit != ik2->unit_pairs[i].base_unit) ||
            (ik1->unit_pairs[i].power != ik2->unit_pairs[i].power))
                return FALSE;
    return TRUE;
}
```

The function compare_unit_sequences is called from 7/kov.

§**10.** We now have three fundamental operations we can perform on unit sequences. First, we can multiply them: that is, we store in `result` the unit sequence representing $X_1^{s_1} X_2^{s_2}$, where X_1 and X_2 are represented by unit sequences `us1` and `us2`.

So the case $s_1 = s_2 = 1$ represents multiplying X_1 by X_2, while $s_1 = 1, s_2 = -1$ represents dividing X_1 by X_2. But we can also raise to higher powers.

Our method relies on noting that

$$X_1 = T_{11}^{p_{11}} \cdot T_{12}^{p_{12}} \cdots T_{1n}^{p_{1n}}, \qquad X_2 = T_{21}^{p_{21}} \cdot T_{22}^{p_{22}} \cdots T_{2m}^{p_{2m}}$$

where $T_{11} < T_{12} < ... < T_{1n}$ and $T_{21} < T_{22} < ... < T_{2m}$. We can therefore merge the two in a single pass.

On each iteration of the loop the variables `i1` and `i2` are our current read positions in each sequence, while we are currently looking at the unit pairs (`t1`, `m1`) and (`t2`, `m2`). The following symmetrical algorithm holds on to each pair until the one from the other sequence has had a chance to catch up with it, because we always deal with the pair with the numerically lower `t` first. This also proves that the `results` sequence comes out in numerical order.

```
void multiply_unit_sequences(unit_sequence *us1, int s1, unit_sequence *us2, int s2,
    unit_sequence *result) {
    if ((result == us1) || (result == us2)) internal_error("result must be different structure");
    result->no_unit_pairs = 0;
    int i1 = 0, i2 = 0;                                          read position in sequences 1, 2
    int t1 = UNKNOWN, p1 = 0;                                    start with no current term from sequence 1
    int t2 = UNKNOWN, p2 = 0;                                    start with no current term from sequence 2
    while (TRUE) {
        ⟨If we have no current term from sequence 1, and it hasn't run out, fetch a new one 11⟩;
        ⟨If we have no current term from sequence 2, and it hasn't run out, fetch a new one 12⟩;
        if (t1 == t2) {
            if (t1 == UNKNOWN) return;                           both sequences have now run out
            ⟨Both terms refer to the same base unit, so combine these into the result 13⟩;
        } else {
            ⟨The terms refer to different base units, so copy the numerically lower one into the result 14⟩;
        }
    }
}
```

§**11.**

⟨If we have no current term from sequence 1, and it hasn't run out, fetch a new one 11⟩ ≡

```
if ((t1 == UNKNOWN) && (us1) && (i1 < us1->no_unit_pairs)) {
    t1 = us1->unit_pairs[i1].base_unit; p1 = us1->unit_pairs[i1].power; i1++;
}
```

This code is used in §10.

§**12.**

⟨If we have no current term from sequence 2, and it hasn't run out, fetch a new one 12⟩ ≡

```
if ((t2 == UNKNOWN) && (us2) && (i2 < us2->no_unit_pairs)) {
    t2 = us2->unit_pairs[i2].base_unit; p2 = us2->unit_pairs[i2].power; i2++;
}
```

This code is used in §10.

§**13.** So here the head of one sequence is T^{p_1} and the head of the other is T^{p_2}, so in the product we ought to see $(T^{p_1})^{s_1} \cdot (T^{p_2})^{s_2} = T^{p_1 s_1 + p_2 s_2}$. But we don't enter terms that have cancelled out, that is, where $p_1 s_1 + p_2 s_2 = 0$.

⟨Both terms refer to the same base unit, so combine these into the result 13⟩ ≡

```
int p = p1*s1 + p2*s2;                                   combined power of t1 = t2
if (p != 0) {
    if (result->no_unit_pairs == MAX_BASE_UNITS_IN_SEQUENCE)
        ⟨Trip a unit sequence overflow 15⟩;
    result->unit_pairs[result->no_unit_pairs].base_unit = t1;
    result->unit_pairs[result->no_unit_pairs++].power = p;
}
t1 = UNKNOWN; t2 = UNKNOWN;                              dispose of both terms as dealt with
```

This code is used in §10.

§**14.** Otherwise we copy. By copying the numerically lower term, we can be sure that it will never occur again in either sequence. So we can copy it straight into the results.

The code is slightly warped by the fact that `UNKNOWN`, representing the end of the sequence, happens to be numerically lower than all the valid data types. We don't want to make use of facts like that, so we write code to deal with `UNKNOWN` explicitly.

⟨The terms refer to different base units, so copy the numerically lower one into the result 14⟩ ≡

```
if ((t2 == UNKNOWN) || ((t1 != UNKNOWN) && (t1 < t2))) {
    if (result->no_unit_pairs == MAX_BASE_UNITS_IN_SEQUENCE)
        ⟨Trip a unit sequence overflow 15⟩;
    result->unit_pairs[result->no_unit_pairs].base_unit = t1;
    result->unit_pairs[result->no_unit_pairs++].power = p1*s1;
    t1 = UNKNOWN;                                  dispose of the head of sequence 1 as dealt with
} else if ((t1 == UNKNOWN) || ((t2 != UNKNOWN) && (t2 < t1))) {
    if (result->no_unit_pairs == MAX_BASE_UNITS_IN_SEQUENCE)
        ⟨Trip a unit sequence overflow 15⟩;
    result->unit_pairs[result->no_unit_pairs].base_unit = t2;
    result->unit_pairs[result->no_unit_pairs++].power = p2*s2;
    t2 = UNKNOWN;                                  dispose of the head of sequence 1 as dealt with
} else internal_error("unit pairs disarrayed");
```

This code is used in §10.

§**15.** For reasons explained above, this is really never going to happen by accident, but we'll be careful:

⟨Trip a unit sequence overflow 15⟩ ≡
```
sentence_problem(_P_(C7UnitSequenceOverflow),
    "reading that sentence led me into calculating such a complicated "
    "kind of value that I ran out of memory",
    "which my programmer really didn't expect to happen. I think you "
    "must have made an awful lot of numerical kinds of value, and "
    "then specified how they multiply so that one of them became "
    "weirdly tricky. Can you simplify?");
return;
```

This code is used in §13,14,13,14,13,14.

§**16.** The second operation is taking roots.

Surprisingly, perhaps, it's much easier to compute $\sqrt{X}$ or $\sqrt[3]{X}$ for any unit X – it's just that it can't always be done. Inform does not permit non-integer powers of units, so for instance $\sqrt{\text{time}}$ does not exist, whereas $\sqrt{\text{length}^2 \cdot \text{mass}^{-2}}$ does. Square roots exist if each power in the sequence is even, cube roots exist if each is divisible by 3. We return `TRUE` or `FALSE` according to whether the root could be taken, and if `FALSE` then the contents of `result` are undefined.

```
int root_unit_sequence(unit_sequence *us, int pow, unit_sequence *result) {
    *result = *us;
    int i;
    for (i=0; i<result->no_unit_pairs; i++) {
        if ((result->unit_pairs[i].power) % pow != 0) return FALSE;
        result->unit_pairs[i].power = (result->unit_pairs[i].power)/pow;
    }
    return TRUE;
}
```

§**17.** The final operation on unit sequences is substitution. Given a base type B, we substitute $B = K_D$ into an existing unit sequence K_E. (This is used when B is becoming a derived type – once we discover that $B = K_D$, we are no longer allowed to keep B in any unit sequence.)

We simply search for B^p, and if we find it, we remove it and then multiply by K_D^p.

```
void dim_substitute(unit_sequence *existing, int base, unit_sequence *derived) {
    int i, j, p = 0, found = FALSE;
    if (existing == NULL) return;
    for (i=0; i<existing->no_unit_pairs; i++)
        if (existing->unit_pairs[i].base_unit == base) {
            p = existing->unit_pairs[i].power;
            found = TRUE;
            ⟨Remove the B term from the existing sequence 18⟩;
        }
    if (found)
        ⟨Multiply the existing sequence by a suitable power of B's derivation 19⟩;
}
```

§**18.** We shuffle the remaining terms in the sequence down by one, overwriting B:

⟨Remove the B term from the existing sequence 18⟩ ≡
```
for (j = --(existing->no_unit_pairs); j>=i; j--)
    existing->unit_pairs[j] = existing->unit_pairs[j+1];
```
This code is used in §17.

§**19.** We now multiply by K_D^p.

⟨Multiply the existing sequence by a suitable power of B's derivation 19⟩ ≡
```
unit_sequence result;
multiply_unit_sequences(existing, 1, derived, p, &result);
*existing = result;
```
This code is used in §17.

§**20.** For reasons which will be explained below, a unit sequence also has a scale factor associated with it:

```
int us_get_scaling_factor(unit_sequence *us) {
    if (us == NULL) return 1;
    return us->scaling_factor;
}
```
The function us_get_scaling_factor is called from 7/kov.

§**21.** That just leaves, as usual, indexing...

```
void index_unit_sequence(unit_sequence *deriv) {
    if (deriv == NULL) internal_error("indexed null unit sequence");
    if (deriv->no_unit_pairs == 0) { INDEX("dimensionless"); return; }
    int j;
    for (j=0; j<deriv->no_unit_pairs; j++) {
        if (j>0) INDEX(".");
        INDEX("(");
        index_data_type_name(deriv->unit_pairs[j].base_unit, FALSE);
        INDEX(")");
        if (deriv->unit_pairs[j].power != 1)
            INDEX("<sup>%d</sup>", deriv->unit_pairs[j].power);
    }
}
```

§**22.** ...and logging.

```
void log_unit_sequence(unit_sequence *deriv) {
    if (deriv == NULL) { LOG("<null-us>"); return; }
    if (deriv->no_unit_pairs == 0) { LOG("dimensionless"); return; }
    int j;
    for (j=0; j<deriv->no_unit_pairs; j++) {
        if (j>0) LOG(".");
        LOG("("); log_data_type_name(deriv->unit_pairs[j].base_unit); LOG(")");
        if (deriv->unit_pairs[j].power != 1)
            LOG("%d", deriv->unit_pairs[j].power);
    }
}
```
The function log_unit_sequence is called from 7/kov.

§**23. Performing derivations.** The following is called when the user specifies that L times R specifies an O. These are required all to be quasinumerical: any of the three might be either a base unit (so far) or a derived unit (already).

If two or more are base units, we have a choice. That is, suppose we have created three KOVs already: mass, acceleration, force. Then we read:

Mass times acceleration specifies a force.

We could make this true in any of three ways: keep M and A as base units and derive F from them, keep A and F as base units and derive M from those, or keep M and F while deriving A. Inform always chooses the most recently created unit as the one to derive, on the grounds that the source text has probably set things out with what the user thinks are the most fundamental units first.

```
void make_unit_derivation(int left, int right, int outcome) {
    int types[3];
    types[0] = left; types[1] = right; types[2] = outcome;
    int newest_base = -1;
    ⟨Find which (if any) of the three units is the newest-made base unit 24⟩;
    if (newest_base >= 0) {
        unit_sequence *derivation = NULL;
        ⟨Derive the newest one by rearranging the equation in terms of the other two 25⟩;
        ⟨Substitute this new derivation to eliminate this base unit from other sequences 26⟩;
    } else
        ⟨Check this derivation to make sure it is redundant, not contradictory 27⟩;
}
```

§**24.** Data type IDs are allocated in creation order, so "newest" means largest ID.

⟨Find which (if any) of the three units is the newest-made base unit 24⟩ ≡

```
    int i, max = 0;
    for (i=0; i<3; i++)
        if ((types[i] > max) && (data_type_test_if_derived(types[i]) == FALSE)) {
            newest_base = i; max = types[i];
        }
```

This code is used in §23.

§**25.** We need to ensure that the user's multiplication rule is henceforth true, and we do that by fixing the newest unit to make it so.

⟨Derive the newest one by rearranging the equation in terms of the other two 25⟩ ≡

```
    unit_sequence *kx = NULL, *ky = NULL; int sx = 0, sy = 0;
    switch (newest_base) {
        case 0:                                          here L is newest and we derive L = R^-1 O
            kx = data_type_get_unit_sequence(types[1]); sx = -1;
            ky = data_type_get_unit_sequence(types[2]); sy = 1;
            break;
        case 1:                                          here R is newest and we derive R = L^-1 O
            kx = data_type_get_unit_sequence(types[0]); sx = -1;
            ky = data_type_get_unit_sequence(types[2]); sy = 1;
            break;
        case 2:                                          here O is newest and we derive O = LR
            kx = data_type_get_unit_sequence(types[0]); sx = 1;
            ky = data_type_get_unit_sequence(types[1]); sy = 1;
```

```
        break;
}
derivation = data_type_get_unit_sequence(types[newest_base]);
unit_sequence result;
multiply_unit_sequences(kx, sx, ky, sy, &result);
*derivation = result;
data_type_now_derived(types[newest_base]);
```

This code is used in §23.

§**26.** Later in Inform's run, when we start compiling code, many more unit sequences will exist on a temporary basis – as part of the KOVs for intermediate results in calculations – but early on, when we're here, the only unit sequences made are the derivations of the units. So it is easy to cover all of them.

⟨Substitute this new derivation to eliminate this base unit from other sequences 26⟩ ≡

```
int r;
LOOP_OVER_POSSIBLE_TYPE_IDS(r)
    if (data_type_is_quasinumerical(r)) {
        unit_sequence *existing = data_type_get_unit_sequence(r);
        dim_substitute(existing, types[newest_base], derivation);
    }
```

This code is used in §23.

§**27.** If we have $AB = C$ but all three of A, B, C are already derived, that puts us in a bind. Their definitions are fixed already, so we can't simply force the equation to come true by fixing one of them. That means either the derivation is redundant – because it's already true that $AB = C$ – or contradictory – because we know $AB \neq C$. We silently allow a redundancy, as it may have been put in for clarity, or so that the user can check the consistency of his own definitions, or to make the Kinds index page more helpful. But we must reject a contradiction.

⟨Check this derivation to make sure it is redundant, not contradictory 27⟩ ≡

```
unit_sequence product;
multiply_unit_sequences(
    data_type_get_unit_sequence(types[0]), 1,
    data_type_get_unit_sequence(types[1]), 1, &product);
if (compare_unit_sequences(&product, data_type_get_unit_sequence(types[2])) == FALSE)
    sentence_problem(_P_(C7DimensionsInconsistent),
        "this is inconsistent with what is already known about those kinds of value",
        "all three of which already have well-established relationships - see the "
        "Kinds index for more.");
```

This code is used in §23.

§**28. Classifying the units.** As noted above, we have base units and we have derived units.

```
int data_type_base(int t) {
    if ((data_type_is_quasinumerical(t)) &&
        (data_type_test_if_derived(t) == FALSE) &&
        (data_type_dimensionless(t) == FALSE) &&
        (t != INTERMEDIATE_TY)) return TRUE;
    return FALSE;
}
int data_type_derived(int t) {
    if (t == INTERMEDIATE_TY) return TRUE;
    if ((data_type_is_quasinumerical(t)) &&
        (data_type_test_if_derived(t) == TRUE) &&
        (data_type_dimensionless(t) == FALSE)) return TRUE;
    return FALSE;
}
```

§**29.** Some of the derived units are dimensionless, others not. `NUMBER_TY` is always dimensionless; and any unit whose derivation is the empty unit sequence must be dimensionless.

```
int data_type_dimensionless(int t) {
    if (t == NUMBER_TY) return TRUE;
    if (data_type_is_quasinumerical(t) == FALSE) return FALSE;
    unit_sequence *deriv = data_type_get_unit_sequence(t);
    if ((deriv) && (deriv->no_unit_pairs == 0)) return TRUE;
    return FALSE;
}
```

The function data_type_dimensionless is called from 7/kov.

§**30.** Using these definitions, we can now print analyses of the units into the index and the debugging log.

```
void index_dimensional_rules(void) {
    INDEX("<p><hr><p>");
    ⟨Index the rubric about quasinumerical KOVs 31⟩;
    ⟨Index the table of quasinumerical KOVs 32⟩;
    ⟨Index the table of multiplication rules 35⟩;
}
```

The function index_dimensional_rules is called from 9/inpw.

§31.

⟨Index the rubric about quasinumerical KOVs 31⟩ ≡

```
INDEX("<a name=calculator>");
begin_plain_html_table(ifl);
first_html_column(ifl, 0);
INDEX("<img border=0 src=inform:/doc_images/calc2.png>");
next_html_column(ifl, 0);
INDEX("Kinds of value marked with the <b>calculator symbol</b> are numerical - "
    "these are values we can add, multiply and so on. The range of these "
    "numbers depends on the Format setting for the project (Glulx format "
    "supports much higher numbers than Z-code).");
end_html_row(ifl);
end_html_table(ifl);
INDEX("<p>");
```

This code is used in §30.

§32.

⟨Index the table of quasinumerical KOVs 32⟩ ≡

```
int r;
begin_plain_html_table(ifl);
first_html_column(ifl, 0);
INDEX("<b>kind of value</b>");
next_html_column(ifl, 0);
INDEX("<b>minimum</b>");
next_html_column(ifl, 0);
INDEX("<b>maximum</b>");
next_html_column(ifl, 0);
INDEX("<b>dimensions</b>");
end_html_row(ifl);
LOOP_OVER_POSSIBLE_TYPE_IDS(r)
    if (data_type_is_quasinumerical(r)) {
        if (r == INTERMEDIATE_TY) continue;
        first_html_column(ifl, 0);
        index_data_type_name(r, FALSE);
        next_html_column(ifl, 0);
        ⟨Index the minimum positive value for a quasinumerical KOV 33⟩;
        next_html_column(ifl, 0);
        ⟨Index the maximum positive value for a quasinumerical KOV 34⟩;
        next_html_column(ifl, 0);
        if (data_type_dimensionless(r)) INDEX("<i>dimensionless</i>");
        else {
            unit_sequence *deriv = data_type_get_unit_sequence(r);
            index_unit_sequence(deriv);
        }
        end_html_row(ifl);
    }
end_html_table(ifl); INDEX("<p>");
```

This code is used in §30.

§**33.** At run-time, the minimum positive value is of course 1, but because of scaling this can appear to be much lower.

⟨Index the minimum positive value for a quasinumerical KOV 33⟩ ≡

```
switch (r) {
    case NUMBER_TY: INDEX("1"); break;
    case TIME_TY: INDEX("1 minute"); break;
    default: lp_index_value(data_type_list_of_literal_forms(r), 1); break;
}
```

This code is used in §32.

§**34.**

⟨Index the maximum positive value for a quasinumerical KOV 34⟩ ≡

```
switch (r) {
    case NUMBER_TY:
        if (target_VM_is_16_bit()) INDEX("32767");
        else INDEX("2147483647");
        break;
    case TIME_TY: INDEX("23 hours 59 minutes"); break;
    default:
        if (target_VM_is_16_bit())
            lp_index_value(data_type_list_of_literal_forms(r), 32767);
        else
            lp_index_value(data_type_list_of_literal_forms(r), 2147483647);
        break;
}
```

This code is used in §32.

§**35.** This is simply a table of all the multiplications declared in the source text, sorted into data type ID order of left and then right operand.

⟨Index the table of multiplication rules 35⟩ ≡

```
int L, R, O, NP = 0, wn;
LOOP_OVER_MULTIPLICATIONS(L, R, O, wn) {
    if (NP++ == 0) {
        INDEX("<p>This is how multiplication changes kinds:<p>\n");
        begin_plain_html_table(ifl);
    }
    first_html_column(ifl, 0);
    if (wn >= 0) index_link(lw_array[wn].lw_source);
    next_html_column(ifl, 0);
    index_data_type_name(L, FALSE);
    INDEX("<font color=\"#808080\"> x </font>");
    index_data_type_name(R, FALSE);
    INDEX("<font color=\"#808080\"> = </font>");
    index_data_type_name(O, FALSE);
    INDEX("    ");
    next_html_column(ifl, 0);
    data_type_index_benchmark_value(L);
    INDEX("<font color=\"#808080\"> x </font>");
    data_type_index_benchmark_value(R);
    INDEX("<font color=\"#808080\"> = </font>");
```

```
        data_type_index_benchmark_value(0);
        end_html_row(ifl);
    }
    if (NP > 0) { end_html_table(ifl); INDEX("<p>"); }
```

This code is used in §30.

§**36.** A simpler format for the debugging log, which is printed when we ask for the internal "dimensions" test:

```
void log_unit_analysis(void) {
    int c, r;
    LOG("Dimensionless: ");
    c = 0;
    LOOP_OVER_POSSIBLE_TYPE_IDS(r)
        if (data_type_dimensionless(r)) { if (c++ > 0) LOG(", "); log_data_type_name(r); }
    LOG("\nBase units: ");
    c = 0;
    LOOP_OVER_POSSIBLE_TYPE_IDS(r)
        if (data_type_base(r)) { if (c++ > 0) LOG(", "); log_data_type_name(r); }
    LOG("\nDerived units:\n");
    LOOP_OVER_POSSIBLE_TYPE_IDS(r)
        if ((data_type_derived(r)) && (r != INTERMEDIATE_TY)) {
            unit_sequence *deriv = data_type_get_unit_sequence(r);
            log_data_type_name(r); LOG(" = "); log_unit_sequence(deriv); LOG("\n");
        }
}
```

The function log_unit_analysis is called from 13/test.

§**37. Scaling.** Recall that every quasinumerical KOV U has a scale factor k_U, by default 1 and always ≥ 1, such that the true value v is represented at runtime as the I6 integer $k_U v$. For instance, if length is measured in metres but has a scale factor of 1000 then the I6 integer 1 means the true value 1mm, 10 means 1cm, 1000 means 1m. This I6 integer is called the scaled value s, and to reiterate, $s = k_U v$.

Scaled values are convenient, and they have no effect on how we add, subtract, approximate (that is, round off) or take remainder after division. If we have true values v_1 and v_2 with scaled values s_1 and s_2, and s_o is the scaled value for true value $v_1 + v_2$, then

$$s_1 + s_2 = k_U v_1 + k_U v_2 = k_U(v_1 + v_2) = s_o.$$

So ordinary I6 `+` at run-time correctly adds scaled values. But that's not true for all operations, and this is where we deal with that.

§**38.** First, multiplication. This time the values v_1 and v_2 may have different KOVs, which we'll call X and Y, and the result in general will be a third KOV, which we'll call O (for outcome). Then:

$$s_1 s_2 = k_X v_1 \cdot k_Y v_2 = k_O v_1 v_2 \cdot \left(\frac{k_X k_Y}{k_O}\right) = s_o \cdot \left(\frac{k_X k_Y}{k_O}\right)$$

so that simply multiplying the scaled values produces an answer which is too large by a factor of $k_X k_Y / k_O$. We need to correct for that, which we do either by dividing by this factor or multiplying by its reciprocal.

This is all a little delicate since rounding errors may be an issue and since $k_X k_Y / k_O$ is itself evaluated in integer arithmetic. In an ideal world we might use the same k for many units (e.g., $k = 1000$ throughout) and then of course this cancels to just 1000. But in practice people won't always do this – they may use some Babylonian, base 60, units, such as minutes and degrees, for instance, where $k = 3600$ would be more natural.

```
void kov_rescale_multiplication(OUTPUT_STREAM, kind_of_value *kovx, kind_of_value *kovy) {
    if ((kovx == NULL) || (kovy == NULL)) return;
    kind_of_value *kovo = arithmetic_on_kovs(kovx, kovy, TIMES_OPERATION);
    if (kovo == NULL) return;
    int k_X = kov_scale_factor(kovx);
    int k_Y = kov_scale_factor(kovy);
    int k_O = kov_scale_factor(kovo);
    if (k_X*k_Y > k_O) WRITE("/%d", (k_X*k_Y/k_O));
    if (k_X*k_Y < k_O) WRITE("*%d", (k_O/k_X/k_Y));
}
```

The function kov_rescale_multiplication is called from 10/eqns and 12/cinv.

§**39.** Second, division, which is similar.

$$\frac{s_1}{s_2} = \frac{k_X v_1}{k_Y v_2} = k_O \frac{v_1}{v_2} \cdot \left(\frac{k_X}{k_O k_Y}\right) = s_o \cdot \left(\frac{k_X}{k_O k_Y}\right)$$

so this time the excess to correct is a factor of $k_X / k_O k_Y$.

```
void kov_rescale_division(OUTPUT_STREAM, kind_of_value *kovx, kind_of_value *kovy) {
    if ((kovx == NULL) || (kovy == NULL)) return;
    kind_of_value *kovo = arithmetic_on_kovs(kovx, kovy, DIVIDE_OPERATION);
    if (kovo == NULL) return;
    int k_X = kov_scale_factor(kovx);
    int k_Y = kov_scale_factor(kovy);
    int k_O = kov_scale_factor(kovo);
    if (k_O*k_Y > k_X) WRITE("*%d", (k_O*k_Y/k_X));
    if (k_O*k_Y < k_X) WRITE("/%d", (k_X/k_O/k_Y));
}
```

The function kov_rescale_division is called from 10/eqns and 12/cinv.

§**40.** Third, the taking of pth roots, at any rate for $p = 2$ or $p = 3$.

```
void kov_rescale_root(OUTPUT_STREAM, kind_of_value *kovx, int power) {
    if (kovx == NULL) return;
    kind_of_value *kovo = NULL;
    if (power == 2) kovo = arithmetic_on_kovs(kovx, NULL, ROOT_OPERATION);
    if (power == 3) kovo = arithmetic_on_kovs(kovx, NULL, CUBEROOT_OPERATION);
    if (kovo == NULL) return;
    int k_X = kov_scale_factor(kovx);
    int k_O = kov_scale_factor(kovo);
    if (power == 2) ⟨Apply a scaling correction for square roots 41⟩
    else if (power == 3) ⟨Apply a scaling correction for cube roots 42⟩
    else internal_error("can only scale square and cube roots");
}
```

The function kov_rescale_root is called from 10/eqns and 12/cinv.

§**41.** For square roots,

$$\sqrt{s} = \sqrt{k_X v} = \sqrt{k_X}\sqrt{v} = k_O\sqrt{v} \cdot \left(\frac{\sqrt{k_X}}{k_O}\right) = s_o \cdot \left(\frac{\sqrt{k_X}}{k_O}\right)$$

and now the overestimate is a factor of $k = \sqrt{k_X}/k_O$. However, rather than calculating $k\sqrt{x}$ we calculate $\sqrt{k^2 x}$, since this way accuracy losses in taking the square root are much reduced. Therefore this scaling operating is to be performed inside the root function, not outside, and it scales by k^2 not k:

⟨Apply a scaling correction for square roots 41⟩ ≡

```
    if (k_O*k_O > k_X) WRITE("*%d", (k_O*k_O/k_X));
    if (k_O*k_O < k_X) WRITE("/%d", (k_X/k_O/k_O));
```

This code is used in §40.

§**42.** For cube roots,

$$\sqrt[3]{s} = \sqrt[3]{k_X v} = \sqrt[3]{k_X}\sqrt[3]{v} = k_O\sqrt[3]{v} \cdot \left(\frac{\sqrt[3]{k_X}}{k_O}\right) = s_o \cdot \left(\frac{\sqrt[3]{k_X}}{k_O}\right)$$

and the overestimate is $k = \sqrt[3]{k_X}/k_O$. Scaling once again within the rooting function, we scale by k^3:

⟨Apply a scaling correction for cube roots 42⟩ ≡

```
    if (k_O*k_O*k_O > k_X) WRITE("*%d", (k_O*k_O*k_O/k_X));
    if (k_O*k_O*k_O < k_X) WRITE("/%d", (k_X/k_O/k_O/k_O));
```

This code is used in §40.

§**43. Arithmetic on KOVs.** We are finally able to provide our central routine, the one providing a service for the rest of Inform. Given `kov1` and `kov2`, we return the KOV resulting from applying arithmetic operation `op`, or `NULL` if the operation cannot meaningfully be applied. In the case where `op` is a unary operation, `kov2` has no significance and should be `NULL`.

The KOVs here are called operands, because they are what will be operated on.

```
kind_of_value *arithmetic_on_kovs(kind_of_value *kov1, kind_of_value *kov2, int op) {
    if (kov1 == NULL) return NULL;
    if ((arithmetic_op_is_unary(op) == FALSE) && (kov2 == NULL)) return NULL;
    unit_sequence *operand1 = kov_get_dimensional_form(kov1);
    unit_sequence *operand2 = kov_get_dimensional_form(kov2);
    unit_sequence result;
    switch (op) {
        case PLUS_OPERATION:
        case MINUS_OPERATION:
        case EQUALS_OPERATION:
        case APPROXIMATION_OPERATION:
            if (compare_unit_sequences(operand1, operand2)) return kov1;
            return NULL;
        case UNARY_MINUS_OPERATION:
        case REMAINDER_OPERATION:
            return kov1;
        case ROOT_OPERATION:
            root_unit_sequence(operand1, 2, &result);
            break;
        case CUBEROOT_OPERATION:
            root_unit_sequence(operand1, 3, &result);
            break;
        case TIMES_OPERATION:
            multiply_unit_sequences(operand1, 1, operand2, 1, &result);
            break;
        case DIVIDE_OPERATION:
            multiply_unit_sequences(operand1, 1, operand2, -1, &result);
            break;
        case POWER_OPERATION: internal_error("can't dimension-check powers");
        default: internal_error("unimplemented arithmetic operation");
    }
    ⟨Handle calculations entirely between dimensionless units more delicately 44⟩;
    ⟨Identify the result as a known KOV, if possible 45⟩;
    ⟨And otherwise create a KOV as the intermediate result of a calculation 46⟩;
}
```

The function arithmetic_on_kovs is called from 7/tc and 10/eqns.

§**44.** If `result` is the empty unit sequence, we'll identify it as a number, because `NUMBER_TY` is the lowest type ID representing a dimensionless unit. Usually that's good: for instance, it says that a frequency times a time is a number, and not some more exotic dimensionless quantity like an angle.

But it's not so good when the calculation is not really physical at all, but purely mathematical, and all we are doing is working on dimensionless units. For instance, if take an angle θ and double it to 2θ, we don't want Inform to say the result is `NUMBER_TY` – we want 2θ to be another angle. So we make an exception.

⟨Handle calculations entirely between dimensionless units more delicately 44⟩ ≡

```
if (arithmetic_op_is_unary(op)) {
    if (kov_is_dimensionless(kov1)) return kov1;
} else {
    if ((kov_is_dimensionless(kov1)) && (kov_is_dimensionless(kov2))) {
        if (is_kova(kov2, NUMBER_TY)) return kov1;
        if (is_kova(kov1, NUMBER_TY)) return kov2;
        if (kov_compare(kov1, kov2)) return kov1;
    }
}
```

This code is used in §43.

§**45.** If we've produced the right combination of base units to make one of the named units, then we return that as an atomic KOV. For instance, maybe we divided a velocity by a time, and now we find that we have $\mathrm{m} \cdot \mathrm{s}^{-2}$, which turns out to have a name: acceleration.

⟨Identify the result as a known KOV, if possible 45⟩ ≡

```
int r;
LOOP_OVER_POSSIBLE_TYPE_IDS(r)
    if (compare_unit_sequences(&result, data_type_get_unit_sequence(r)))
        return kova(r);
```

This code is used in §43.

§**46.** Otherwise the `result` is a unit sequence which doesn't have a name, so we store it as an `INTERMEDIATE_TY` KOV, representing a temporary value living only for the duration of a calculation.

A last little wrinkle is: how we should scale this? For results like an acceleration, something defined in the source text, we know how accurate the author wants us to be. But these intermediate KOVs are not defined, and we don't know for sure what the author would want. It seems wise to set $k \geq k_X$ and $k \geq k_Y$, so that we have at least as much detail as the calculation would have had within each operand KOV. So perhaps we should put $k = \max(k_X, k_Y)$. But in fact we will choose $k = \mathrm{lcm}(k_X, k_Y)$, the least common multiple, so that any subsequent divisions will cancel correctly and we won't lose too much information through integer rounding. (In practice this will probably either be the same as $\max(k_X, k_Y)$ or will multiply by 6, since $\mathrm{lcm}(60, 1000) = 6000$ and so on.)

The same unit sequence can have different scalings each time it appears as an intermediate calculation. We could get to $\mathrm{m}^2 \cdot \mathrm{kg}$ either as $\mathrm{m} \cdot \mathrm{kg}$ times m, or as m^2 times kg, or many other ways, and we'll get different scalings depending on the route. This is why the `unit_sequence` structure has a `scaling_factor` field; the choice of scale factor does *not* depend on the physics but on the arithmetic method being used.

⟨And otherwise create a KOV as the intermediate result of a calculation 46⟩ ≡

```
result.scaling_factor = lcm(kov_scale_factor(kov1), kov_scale_factor(kov2));
return koviv(&result);
```

This code is used in §43.

Runtime Support for Data Types 9/rsdt

Purpose

To compile I6 material needed at runtime to enable data types to function as they should.

9/rsdt.§1-8 The heap; §9-14 Run-time support for units and enumerations; §15-20 Further runtime support

---

Template interpreter commands

```
2   {-callv:compile_heap_allocator}
9   {-callv:compile_data_type_support_routines}
```

---

§**1. The heap.** Some but not all works compiled by Inform make use of a "heap" of memory at runtime, to hold dynamic strings, lists and other flexibly-sized structures. This is needed only if the source text makes use of data types storing pointer values, which the Standard Rules do not, so on a minimal compilation no heap will be created.

Management of the heap is delegated to runtime code in the template file "Flex.i6t", so Inform itself needs to know surprisingly little about how the job is done. Our main task is to work out how large a heap is likely to be needed. This is important because although some virtual machines (recent versions of Glulx) can dynamically allocate memory and so can grow their heaps, others cannot, so that the initial size needs to be enough to get through the whole run.

We need to keep an approximate count of how much memory will be needed to store the blocks of data pointed to by values of kind "indexed text" and the like: this is of necessity approximate since we cannot know how large such texts might grow, or how much function call recursion will cause more and more texts to proliferate during calculations. Still, we can guess, and in one important case we can be certain: if nobody ever uses any of these pointer-value data types, the memory needed will be exactly 0, and this is worth knowing since it enables us to avoid using even the tiniest amount of the Z-machine's precious byte-addressable memory.

We keep track by spotting the compilation of all calls to create pointer values.

```
int total_heap_allocation = 0, heap_needed = FALSE;

void ensure_basic_heap_present(void) {
    heap_needed = TRUE;
    total_heap_allocation += 256;                    enough for the initial free-space block
}
```

The function ensure_basic_heap_present is called from 7/cmsp and 10/list.

§**2.** We need to provide a start-up routine which creates initial blocks of data on the heap for any permanent storage objects (global variables, property values, table entries, list items) of pointer-value data types:

```
void compile_heap_allocator(OUTPUT_STREAM) {
    WRITE("[ InitialHeapAllocation obj pv;\n"); INDENT;
    ⟨Allocate heap space for global variables with pointer-value KOVs 3⟩;
    ⟨Allocate heap space for properties with pointer-value KOVs 4⟩;
    ⟨Allocate heap space for table entries with pointer-value KOVs 6⟩;
    compile_list_constant_allocations(OUT);
    OUTDENT; WRITE("];\n");
    WRITE("[ DistributeBlockConstants obj pv;\n"); INDENT;
    ⟨Make multiple copies of constant values for properties 5⟩;
    OUTDENT; WRITE("];\n");
    if (heap_needed == FALSE) return;
    ⟨Compile a constant for the heap size needed 7⟩;
}
```

The function compile_heap_allocator is invoked by a command in a `.i6t` template file.

§**3.** For each global variable `Q` we compile code like this:

```
pv = Q;
Q = BlkValueCreate(K, pv, 0);
```

where `K` is the I6 identifier for the KOV, and `pv` represents the initial value – which is usually being cast from a word value; for instance, if we are working from this:

```
Gadget is an indexed text that varies. Gadget is "sonic screwdriver".
```

then we would compile, in effect:

```
pv = "sonic screwdriver";
Q = BlkValueCreate(INDEXED_TEXT_TY, pv, 0);
```

Thus allocating a new block on the heap and casting the word value "sonic screwdriver" (a pointer to an unindexed packed string in the virtual machine) into the new heap block.

However, a few pointer-value KOVs have constants which don't arise from casting: notably, lists. Blocks on the heap for constants like those are made separately, so we only create a new block if the initial value is 0, since this means "not allocated yet". For instance, if `Q` is a list of numbers, we would do this:

```
pv = Q;
if (pv == 0) Q = BlkValueCreate(LIST_OF_TY, pv, NUMBER_TY);
```

⟨Allocate heap space for global variables with pointer-value KOVs 3⟩ ≡

```
quantity *q;
LOOP_OVER(q, quantity)
    if (qty_is_a_global_variable(q)) {
        kind_of_value *kov = qty_kind_of_value(q);
        if (kov_uses_pointer_values(kov)) {
            WRITE("pv = "); compile_quantity_name(OUT, q); WRITE("; ");
            if (kov_has_pointer_value_constants(kov)) WRITE("if (pv==0) ");
            compile_quantity_name(OUT, q); WRITE(" = ");
            compile_heap_allocation(OUT, qty_kind_of_value(q), 1, TRUE);
            WRITE(";\n");
        }
    }
```

This code is used in §2.

§**4.** The same, but for property values of objects and other values.

⟨Allocate heap space for properties with pointer-value KOVs 4⟩ ≡

```
property_name *prn;
LOOP_OVER(prn, property_name) {
    if (prn_is_either_or(prn) == FALSE) {
        kind_of_value *kov = prn_get_kind_of_value(prn);
        if (kov_uses_pointer_values(kov)) {
            WRITE("if (%s) objectloop (obj provides %s) { pv = obj.%s; ",
                prn_get_i6_identifier(prn),
                prn_get_i6_identifier(prn),
                prn_get_i6_identifier(prn));
            if (kov_has_pointer_value_constants(kov)) WRITE("if (pv==0) ");
            WRITE("obj.%s = ", prn_get_i6_identifier(prn));
            compile_heap_allocation(OUT, prn_get_kind_of_value(prn), 1, TRUE);
            WRITE("; }\n", prn_get_i6_identifier(prn));
        }
    }
}
int t;
LOOP_OVER_DATA_TYPE_IDS(t)
    allocate_heap_for_KOV_properties(OUT, kova(t));
```

This code is used in §2.

§**5.** The rationale for the following is: suppose we have

> A person has a stored action called the manoeuvre. The manoeuvre of a person is usually the jumping action.

Then a pointer to the a block which will one day hold the jumping action is the manoeuvre value in the `Class` declaration which the person kind becomes on compilation. That means all people for whom manoeuvre was never explicitly defined will inherit this same pointer as their copy. That in turn means they don't really have independent copies – they all have the same manoeuvre action forever afterwards, making it impossible to alter during play. We must therefore force them to have independent copies, by copying. But that can't be done in the Initial Heap Allocation stage because the values within the blocks don't exist yet; the heap space has to be allocated first, and the values get written later. So we take care of it in a special "distribute block constants" phase of initialisation:

⟨Make multiple copies of constant values for properties 5⟩ ≡

```
property_name *prn;
LOOP_OVER(prn, property_name) {
    if (prn_is_either_or(prn) == FALSE) {
        kind_of_value *kov = prn_get_kind_of_value(prn);
        if ((kov_uses_pointer_values(kov)) &&
            (kov_has_pointer_value_constants(kov))) {
            WRITE("if (%s) objectloop (obj provides %s) { pv = obj.%s; ",
                prn_get_i6_identifier(prn),
                prn_get_i6_identifier(prn),
                prn_get_i6_identifier(prn));
            WRITE("obj.%s = BlkValueCreate(%d); BlkValueCopy(obj.%s, pv); }",
                    prn_get_i6_identifier(prn), kov_I6_ID(kov), prn_get_i6_identifier(prn));
        }
    }
}
```

This code is used in §2.

§**6.** The same, but for table entries. (Note that property values of values which are stored as table entries are taken care of here, too.)

⟨Allocate heap space for table entries with pointer-value KOVs 6⟩ ≡

```
int i;
table *t;
LOOP_OVER(t, table)
    for (i=0; i<tab_no_columns(t); i++) {
        kind_of_value *kov = table_column_data_type(t, i);
        if (kov_uses_pointer_values(kov)) {
            WRITE("for (obj=1:obj<=TableRows(%s):obj++) { ",
                tab_get_I6_representation(t));
            WRITE("if (ExistsTableLookUpEntry(%s, %d, obj)==false) continue; ",
                tab_get_I6_representation(t), i+1);
            WRITE("pv = TableLookUpEntry(%s, %d, obj); ",
                tab_get_I6_representation(t), i+1);
            if (kov_has_pointer_value_constants(kov))
                WRITE("if (pv==0) ");
            WRITE("TableLookUpEntry(%s, %d, obj, true, ",
                tab_get_I6_representation(t), i+1);
            compile_heap_allocation(OUT, table_column_data_type(t, i),
                tab_no_rows(t), TRUE);
            WRITE("); }\n");
        }
    }
```

This code is used in §2.

§**7.** By now, we know that we need at least `total_heap_allocation` bytes on the heap, but the initial heap size has to be a power of 2, so we compute the smallest such which is big enough. On Glulx, we then multiply by 4: one factor of 2 is because the word size is twice as much – words are 4-byte, not 2-byte as on the Z-machine – while the other is, basically, because we can, and because we want to store indexed text in particular using 2-byte characters (capable of storing Unicode) rather than 1-byte characters as on the Z-machine. Glulx has essentially no memory constraints compared with the Z-machine.

⟨Compile a constant for the heap size needed 7⟩ ≡

```
int max_heap = 1;
if (total_heap_allocation < get_dynamic_memory_allocation())
    total_heap_allocation = get_dynamic_memory_allocation();
while (max_heap < total_heap_allocation) max_heap = max_heap*2;
WRITE("#ifdef TARGET_ZCODE;\n");
WRITE("Constant MEMORY_HEAP_SIZE = %d;\n", max_heap);
WRITE("#ifnot;\n");
WRITE("Constant MEMORY_HEAP_SIZE = %d;\n", 4*max_heap);
WRITE("#endif;\n");
LOG("Providing for an total heap of %d, given requirement of %d\n",
    max_heap, total_heap_allocation);
```

This code is used in §2.

§**8.** The following routine both compiles code to create a pointer value, and also increments the heap allocation suitably. Each pointer-value KOV comes with an estimate of its likely size needs – its exact size needs if it is fixed in size, and a reasonable overestimate of typical usage if it is flexible.

The `multiplier` is used when we need to calculate the size of, say, a list of 20 indexed texts. For the cases above, it's always 1.

```
void compile_heap_allocation(OUTPUT_STREAM, kind_of_value *kov,
    int multiplier, int casting) {
    heap_needed = TRUE;
    if (kov_uses_pointer_values(kov) == FALSE)
        internal_error("unable to allocate heap storage for this kind of value");
    if (kov_get_heap_size_estimate(kov) == 0)
        internal_error("no heap storage estimate for this kind of value");
    total_heap_allocation += (kov_get_heap_size_estimate(kov))*multiplier;
    WRITE("BlkValueCreate(%d,", kov_I6_ID(kov));
    if (casting) WRITE("pv,"); else WRITE("0,");
    WRITE("%d)", kov_I6_construct_ID(kov));
}
```

The function compile_heap_allocation is called from 9/prop, 10/list, 12/phsf and 12/stv.

§**9. Run-time support for units and enumerations.** The following generates a small suite of I6 routines associated with each such data type, and needed at run-time.

```
void compile_data_type_support_routines(OUTPUT_STREAM) {
    int t;
    LOOP_OVER_DESIGNED_TYPE_IDS(t) {
        kind_of_value *kov = kova(t);
        char *I6_name_of_kov = kov_get_name_of_printing_rule(kov);
        if (kov_is_an_enumeration(kov)) {
            ⟨Compile I6 printing routine for an enumerated KOV 12⟩;
            ⟨Compile the A and B routines for an enumerated KOV 13⟩;
            ⟨Compile random-ranger routine for this KOV 14⟩;
        } else if (kov_is_a_unit(kov)) {
            ⟨Compile I6 printing routine for a unit KOV 11⟩;
            ⟨Compile random-ranger routine for this KOV 14⟩;
        } else {
            ⟨Compile I6 printing routine for a vacant but named KOV 10⟩;
        }
    }
    ⟨Compile a suite of I6 routines taking KOV IDs as arguments 15⟩;
    LOOP_OVER_DATA_TYPE_IDS(t)
        compile_KOV_properties(OUT, kova(t));
}
```

The function compile_data_type_support_routines is invoked by a command in a `.i6t` template file.

§**10.** A slightly bogus case first. If the source text declares a KOV but never gives any enumerated values or literal patterns, then such values will never appear at run-time; but we need the printing routine to exist to avoid compilation errors.

⟨Compile I6 printing routine for a vacant but named KOV 10⟩ ≡

```
WRITE("[ %s value;\n", I6_name_of_kov); INDENT;
WRITE("print value;\n");
OUTDENT; WRITE("];\n\n");
```

This code is used in §9.

§**11.** A unit is printed back with its earliest-defined literal pattern used as notation. If it had no literal patterns, it would come out as decimal numbers, but at present this can't happen.

⟨Compile I6 printing routine for a unit KOV 11⟩ ≡

```
WRITE("[ %s value ", I6_name_of_kov);
if (kov_list_of_literal_forms(kov))
    printing_routine_for_lp(OUT, kov_list_of_literal_forms(kov));
else {
    WRITE(";\n"); INDENT; WRITE("print value;\n");
}
OUTDENT; WRITE("];\n\n");
```

This code is used in §9.

§**12.**

⟨Compile I6 printing routine for an enumerated KOV 12⟩ ≡

```
WRITE("[ %s value;\n", I6_name_of_kov); INDENT;
WRITE("switch(value) {\n"); INDENT;

quantity *q;
LOOP_OVER(q, quantity) {
    if ((kov_compare(qty_kind_of_value(q), kov)) && (qty_is_a_variable(q) == FALSE)) {
        int k;
        compile_quantity_name(OUT, q);
        WRITE(": print \"");
        for (k=q->word_ref1; k<=q->word_ref2; k++) {
            isn_compile_string(OUT, lw_array[k].lw_rawtext, 0);
            if (k < q->word_ref2) WRITE(" ");
        }
        WRITE("\";\n");
    }
}

this default case should never be needed, unless the user has blundered at the I6 level:
int w1, w2;
kov_get_name(kov, &w1, &w2, FALSE);
WRITE("default: print \"<illegal ");
if (w1 >= 0) print_text_to_file(w1, w2, OUT); else WRITE("value");
WRITE(">\";\n");

OUTDENT; WRITE("}\n");
OUTDENT; WRITE("];\n\n");
```

This code is used in §9.

§**13.** If the type is called, say, `T1_colour`, then we have:

(a) `A_T1_colour(v)` advances to the next valid value for the type, wrapping around to the first from the last;
(b) `B_T1_colour(v)` goes back to the previous valid value for the type, wrapping around to the last from the first, so that it is the inverse function to `A_T1_colour(v)`.

⟨Compile the A and B routines for an enumerated KOV 13⟩ ≡

```
int j = kov_get_highest_valid_value_as_integer(kov);
WRITE("[ A_%s value;\n", I6_name_of_kov); INDENT;
WRITE("return (value %% %d)+1;\n", j);
OUTDENT; WRITE("];\n");
WRITE("[ B_%s value;\n", I6_name_of_kov); INDENT;
WRITE("return ((value+%d) %% %d)+1;\n", j-2, j);
OUTDENT; WRITE("];\n");
```

This code is used in §9.

§**14.** And here we add:

(a) `R_T1_colour()` returns a uniformly random choice of the valid values of the given type. (For a unit, this will be a uniformly random positive value, which will probably not be useful.)
(b) `R_T1_colour(a, b)` returns a uniformly random choice in between `a` and `b` inclusive.

⟨Compile random-ranger routine for this KOV 14⟩ ≡

```
WRITE("[ R_%s a b;\n", I6_name_of_kov); INDENT;
if (kov_is_a_unit(kov))
    WRITE("if (a == 0 && b == 0) return (random(MAX_POSITIVE_NUMBER));\n");
else
    WRITE("if (a == 0 && b == 0) return (random(%d));\n",
        kov_get_highest_valid_value_as_integer(kov));
WRITE("if (a == b) return b;\n");
WRITE("if (a > b) return b+(random(MAX_POSITIVE_NUMBER) %% (a-b+1));\n");
WRITE("return a+(random(MAX_POSITIVE_NUMBER) %% (b-a+1));\n");
OUTDENT; WRITE("];\n");
```

This code is used in §9.

§**15. Further runtime support.** These last routines are synoptic: they take the ID number of the KOV as an argument, so there is only one of each routine.

⟨Compile a suite of I6 routines taking KOV IDs as arguments 15⟩ ≡

```
⟨Compile PrintKindValuePair 16⟩;
⟨Compile DefaultValueOfKOV 17⟩;
⟨Compile KOVComparisonFunction 18⟩;
⟨Compile KOVIsBlockValue 19⟩;
⟨Compile KOVSupportFunction 20⟩;
```

This code is used in §9.

§**16.** `PrintKindValuePair(K, V)` prints out the value `V`, declaring its KOV to be `K`. (Since I6 is typeless and in general the KOV of `V` cannot be deduced from its value alone, `K` must explicitly be supplied.)

⟨Compile PrintKindValuePair 16⟩ ≡
```
WRITE("[ PrintKindValuePair k v;\n"); INDENT;
WRITE("  switch(k) {\n"); INDENT;
LOOP_OVER_DATA_TYPE_IDS(t)
    WRITE("%d: print (%s) v;\n",
        t, data_type_get_name_of_printing_rule(t));
WRITE("default: print v;\n");
OUTDENT; WRITE("}\n");
OUTDENT; WRITE("];\n");
```

This code is used in §15.

§**17.** `DefaultValueOfKOV(K)` returns the default value for KOV `K`: it's needed, for instance, when increasing the size of a list of K to include new entries, which have to be given some type-safe value to start out at.

⟨Compile DefaultValueOfKOV 17⟩ ≡
```
WRITE("[ DefaultValueOfKOV k;\n"); INDENT;
WRITE("switch(k) {\n"); INDENT;
LOOP_OVER_DATA_TYPE_IDS(t)
    if (data_type_can_be_stored_in_variables(t)) {
        WRITE("%d: return ", t);
        compile_default_value(OUT, kova(t), -1, -1, "list entry");
        WRITE(";\n");
    }
WRITE("default: return 0;\n");
OUTDENT; WRITE("}\n");
OUTDENT; WRITE("];\n");
```

This code is used in §15.

§**18.** `KOVComparisonFunction(K)` returns either the address of a function to perform a comparison between two values, or else 0 to signal that no special sort of comparison is needed. (In which case signed numerical comparison will be used.) The function `F` may be used in a sorting algorithm, so it must have no side-effects. `F(x,y)` should return 1 if $x > y$, 0 if $x = y$ and -1 if $x < y$. Note that it is not permitted to return 0 unless the two values are genuinely equal.

⟨Compile KOVComparisonFunction 18⟩ ≡
```
WRITE("[ KOVComparisonFunction k;\n"); INDENT;
WRITE("switch(k) {\n"); INDENT;
LOOP_OVER_DATA_TYPE_IDS(t)
    if (data_type_can_be_stored_in_variables(t)) {
        if (data_type_uses_pointer_values(t))
            WRITE("%d: return BlkValueCompare;\n", t);
        else if (data_type_uses_signed_comparisons(t) == FALSE)
            WRITE("%d: return UnsignedCompare;\n", t);
    }
WRITE("default: return 0;\n");
OUTDENT; WRITE("}\n");
OUTDENT; WRITE("];\n");
```

This code is used in §15.

§**19.** `KOVIsBlockValue(K)` is true if and only if `K` is the I6 ID of a KOV storing pointers to blocks on the heap.

⟨Compile KOVIsBlockValue 19⟩ ≡
```
WRITE("[ KOVIsBlockValue k;\n"); INDENT;
WRITE("if (k == ");
int j = 0;
LOOP_OVER_DATA_TYPE_IDS(t)
    if (data_type_uses_pointer_values(t)) {
        if (j++ > 0) WRITE(" or ");
        WRITE("%d", t);
    }
WRITE(") rtrue;\n");
WRITE("rfalse;\n");
OUTDENT; WRITE("];\n");
```

This code is used in §15.

§**20.** `KOVSupportFunction(K)` returns the address of the specific support function for a pointer-value KOV `K`, or returns 0 if `K` is not such a KOV. For what such a function does, see "Flex.i6t" and the example in, for instance, "IndexedText.i6".

⟨Compile KOVSupportFunction 20⟩ ≡
```
WRITE("[ KOVSupportFunction k;\n"); INDENT;
WRITE("switch(k) {\n"); INDENT;
LOOP_OVER_DATA_TYPE_IDS(t)
    if (data_type_uses_pointer_values(t))
        WRITE("%d: return %s_Support;\n", t, type_ID_get_source_name(t));
OUTDENT; WRITE("}\n");
WRITE("rfalse;\n");
OUTDENT; WRITE("];\n");
```

This code is used in §15.

Kinds Index 7/kix

Purpose

To produce most of the Kinds page in the Index for a project: the chart at the top, and the detailed entries below.

§1. Indexing the KOVs. The Kinds page of the index opens with a table summarising the hierarchy of KOVs (and therefore of objects too), and then follows with details. This routine is called twice, once with `pass` equal to 1, when it has to fill in the hierarchy of KOVs listed under "value" in the key chart at the top of the Kinds index; and then again lower down, with `pass` equal to 2, when it gives more detail.

Not all of the built-in KOVs are indexed on the Kinds page. The ones omitted are of no help to end users, and would only clutter up the table with misleading entries. Remaining KOVs are grouped together in "priority" order, a device to enable the quasinumerical KOVs to stick together, the enumerative ones, and so on. (The priorities are set in the "Types.i6t" template file; a lower priority number puts you higher up.)

```
int tabulating_kinds_index = FALSE;
void index_kinds_of_value(int pass) {
    int priority;
    int t;
    if (pass == 1) {
        tabulating_kinds_index = TRUE;
        begin_plain_html_table(ifl);
        ⟨Add a titling row to the chart of KOVs 2⟩;
    }
    for (priority = 1; priority <= LOWEST_INDEX_PRIORITY; priority++) {
        LOOP_OVER_DATA_TYPE_IDS(t) {
            if (priority == data_type_get_index_priority(t)) {
                kind_of_value *kov = kova(t);
                if (kov_can_be_stored_in_variables(kov)) {
                    switch (pass) {
                        case 1: ⟨Write table row for this KOV 3⟩; break;
                        case 2:
                            ⟨Write heading for the detailed index entry for this KOV 5⟩;
                            ⟨Index explanatory text supplied for a KOV 8⟩;
                            ⟨Index literal patterns which can specify this KOV 6⟩;
                            ⟨Index possible values of an enumerated KOV 7⟩;
                            INDEX("<p>\n"); break;
                    }
                    if (t == OBJECT_TY) index_object_kinds(pass);
                }
            }
        }
    }
    if (pass == 1) {
        end_html_table(ifl);
        INDEX("<p>\n");
        tabulating_kinds_index = FALSE;
        ⟨Add the rubric below the chart of KOVs 4⟩;
    }
}
```

The function index_kinds_of_value is called from 9/inpw.

§**2.** An atypical row:

⟨Add a titling row to the chart of KOVs 2⟩ ≡

```
first_html_column(ifl, 0);
INDEX("value");
index_KOV_col_head("default value", "default");
index_KOV_col_head("repeat", "repeat");
index_KOV_col_head("props", "props");
index_KOV_col_head("under", "under");
end_html_row(ifl);
```

This code is used in §1.

§**3.** And then a typical row:

⟨Write table row for this KOV 3⟩ ≡

```
char *repeat = "cross", *props = "cross", *under = "cross";
int shaded = FALSE;
if ((data_type_get_highest_valid_value_as_integer(t) == 0) &&
    (data_type_indexed_grey_if_empty(t)))
        shaded = TRUE;
if (kov_compile_domain_possible(kov)) repeat = "tick";
if (kov_has_properties(kov)) props = "tick";
if (kov_offers_I6_GPR(kov)) under = "tick";
index_KOV_begin_chart_row();
index_KOV_name_cell(shaded, t);
index_KOV_end_chart_row(shaded, NULL, t, repeat, props, under);
```

This code is used in §1.

§**4.** Note the named anchors here, which must match those linked from the titling row (in the second argument of `index_KOV_col_head`).

⟨Add the rubric below the chart of KOVs 4⟩ ≡

```
INDEX("<p><a name=col_default>"
    "<small>The <b>default value</b> is used when we make something like "
    "a variable but don't tell Inform what its value is. For instance, if "
    "we write 'Zero hour is a time that varies', but don't tell Inform "
    "anything specific like 'Zero hour is 11:21 PM.', then Inform uses "
    "the value in the table above to decide what it will be. "
    "The same applies if we create a property (for instance, 'A person "
    "has a number called lucky number.'). Kinds of value not included "
    "in the table cannot be used in variables and properties.</small>"
    "<p><a name=col_repeat>"
    "<small>A tick for <b>repeat</b> means that it's possible to "
    "repeat through values of this kind. For instance, 'repeat with T "
    "running through times:' is allowed, but 'repeat with N running "
    "through numbers:' is not - there are too many numbers for this to "
    "make sense. A tick here also means it's possible to form lists such "
    "as 'list of rulebooks', or to count the 'number of scenes'.</small>"
    "<p><a name=col_props>"
    "<small>A tick for <b>props</b> means that values of this "
    "kind can have properties. For instance, 'A scene can be thrilling or "
```

```
        "dull.' makes an either/or property of a scene, but 'A number can be "
        "nice or nasty.' is not allowed because it would cost too much storage "
        "space. (Of course 'Definition:' can always be used to make adjectives "
        "applying to numbers; it's only properties which have storage "
        "worries.)</small>"
        "<p><a name=col_under>"
        "<small>A tick for <b>under</b> means that it's possible "
        "to understand values of this kind. For instance, 'Understand \"award "
        "[number]\" as awarding.' might be allowed, if awarding were an action "
        "applying to a number, but 'Understand \"run [rule]\" as rule-running.' "
        "is not allowed - there are so many rules with such long names that "
        "Inform doesn't add them to its vocabulary during play.</small><p>");
```

This code is used in §1.

§**5.** The detailed entry lower down the page begins with:

⟨Write heading for the detailed index entry for this KOV 5⟩ ≡

```
    index_anchor_numbered(t);                                   ...the anchor to which the grey icon in the table led
    INDEX("<b>"); index_data_type_name(t, TRUE); INDEX("</b>");
    INDEX(" (<i>plural</i> "); index_data_type_plural(t); INDEX(")");
    if (data_type_get_documentation_reference(t))
        index_doc_link(data_type_get_documentation_reference(t));                blue help icon, if any
    INDEX("<br>");
```

This code is used in §1.

§**6.**

⟨Index literal patterns which can specify this KOV 6⟩ ≡

```
    if ((kov_is_a_unit(kov)) && (data_type_list_of_literal_forms(t))) {
        index_literal_patterns(t);
        INDEX("<br>");
    }
```

This code is used in §1.

§**7.** Note that an enumerated KOV only becomes so when its first possible value is made, so that the following sentence can't have an empty list in it.

⟨Index possible values of an enumerated KOV 7⟩ ≡

```
    if (kov_is_an_enumeration(kov)) {
        int f = FALSE;
        quantity *q;
        INDEX("<i>One of the following:</i> ");
        LOOP_OVER(q, quantity) {
            if ((kov_compare(qty_kind_of_value(q), kov)) && (qty_is_a_variable(q) == FALSE)) {
                if (f) INDEX(", ");
                print_raw_text_to_file(q->word_ref1, q->word_ref2, ifl);
                f = TRUE;
            }
        }
        INDEX("<br>");
    }
```

This code is used in §1.

§**8.** Explanations:

⟨Index explanatory text supplied for a KOV 8⟩ ≡

```
    char *explanation = kov_get_specification_text(kov);
    if (explanation) INDEX("%s<br>\n", explanation);
```

This code is used in §1.

§**9. KOV table construction.** First, here's the table cell for the heading at the top of a column: the link is to the part of the rubric explaining what goes into the column.

```
void index_KOV_col_head(char *name, char *anchor) {
    next_html_column(ifl, 0);
    INDEX("<i>%s</i> ", name);
    INDEX("<a href=#col_%s><img border=0 src=inform:/doc_images/shelp.png></a>", anchor);
}
```

§**10.** Once we're past the heading row, each row is made in two parts: first this is called –

```
void index_KOV_begin_chart_row(void) {
    first_html_column(ifl, 0);
}
```

The function index_KOV_begin_chart_row is called from 9/inpw.

§**11.** That leads us into the cell for the name of the KOV. The following routine is used for the KOV rows, but not for the kinds-of-object rows; the cell for those is filled in a different way in "Index Physical World".

It's convenient to return the shadedness: a row is shaded if it's for a KOV which can have enumerated values but doesn't at the moment – for instance, the sound effects row is shaded if there are none.

define KINDS_INDEX_SHADE "#808080" *standard HTML grey colour*

```
int index_KOV_name_cell(int shaded, int t) {
    if (shaded) INDEX("<font color=\"%s\">", KINDS_INDEX_SHADE);
    INDEX("    ");
    index_data_type_name(t, TRUE);
    if (kov_quasinumerical(kova(t)))
        INDEX(" <a href=#calculator><img border=0 src=inform:/doc_images/calc1.png></a>");
    if (data_type_get_highest_valid_value_as_integer(t) >= 1)
        INDEX(" [%d]", data_type_get_highest_valid_value_as_integer(t));
    index_below_link_numbered(t);                    a grey see below icon leading to an anchor on pass 2
    if (data_type_get_documentation_reference(t))
        index_doc_link(data_type_get_documentation_reference(t));
    if (shaded) INDEX("</font>");
    return shaded;
}
```

§**12.** Finally we close the name cell, add the remaining cells, and close out the whole row.

```
void index_KOV_end_chart_row(int shaded, world_object *k, int t,
    char *tick1, char *tick2, char *tick3) {
    next_html_column(ifl, 0);
    if (shaded) INDEX("<font color=\"%s\">", KINDS_INDEX_SHADE);
    ⟨Index the default value entry in the KOV chart 13⟩;
    if (shaded) INDEX("</font>");
    next_html_column(ifl, 0);
    INDEX("<img border=0 alt=\"%s\" src=inform:/doc_images/%s%s.png>",
        tick1, shaded?"grey":"", tick1);
    next_html_column(ifl, 0);
    INDEX("<img border=0 alt=\"%s\" src=inform:/doc_images/%s%s.png>",
        tick2, shaded?"grey":"", tick2);
    next_html_column(ifl, 0);
    INDEX("<img border=0 alt=\"%s\" src=inform:/doc_images/%s%s.png>",
        tick3, shaded?"grey":"", tick3);
    end_html_row(ifl);
}
```

The function index_KOV_end_chart_row is called from 9/inpw.

§**13.** For a kind of object, we get the default value by looking for the earliest created instance; for a KOV, the default comes from the value specified in the "Types.i6t" declaration, except that two special values expand:

⟨Index the default value entry in the KOV chart 13⟩ ≡

```
    if (k) {
        int found = FALSE;
        world_object *inst;
        LOOP_OVER(inst, world_object)
            if ((inst->kind_flag == FALSE) && (wo_of_kind(inst, k))) {
                index_name_object(inst, "", "");
                found = TRUE;
                break;
            }
        if (found == FALSE) INDEX("--");
    } else {
        kind_of_value *kov = kova(t);
        char *p = kov_get_index_default_value(kov);
        if (strcmp(p, "<0-in-literal-pattern>") == 0)
            ⟨Index the constant 0 but use the default literal pattern 14⟩
        else if (strcmp(p, "<first-constant>") == 0)
            ⟨Index the earliest-created constant value for this KOV 15⟩
        else INDEX(p);
    }
```

This code is used in §12.

§**14.** For every quasinumeric KOV the default value is 0, but we don't want to index just "0" because that means 0-as-a-number: we want it to come out as "0 kg", "0 hectares", or whatever is appropriate.

⟨Index the constant 0 but use the default literal pattern 14⟩ ≡

```
    if (kov_list_of_literal_forms(kov))
        lp_index_value(kov_list_of_literal_forms(kov), 0);
    else
        INDEX("--");
```

This code is used in §13.

§**15.**

⟨Index the earliest-created constant value for this KOV 15⟩ ≡

```
    int found = FALSE;
    quantity *q;
    LOOP_OVER(q, quantity) {
        if ((kov_compare(qty_kind_of_value(q), kov)) &&
            (qty_is_a_variable(q) == FALSE)) {
            print_raw_text_to_file(q->word_ref1, q->word_ref2, ifl);
            found = TRUE;
            break;
        }
    }
    if (found == FALSE) INDEX("--");
```

This code is used in §13.

§**16. Indexing data type names.** We need this for other index pages, too, so it's abstracted into routines. Note that we add "any kind" for constructors, so that "list of" becomes "list of any kind".

```
void index_data_type_name(int t, int with_links) {
    if (type_IDs_table[t].word_ref1 >= 0) {
        index_lowercase_dtid(t);
        if (with_links) index_link(lw_array[type_IDs_table[t].word_ref1].lw_source);
    } else {
        if (type_IDs_table[t].parsing_name != NULL)
            INDEX("%s", vocab_get_exemplar(type_IDs_table[t].parsing_name, FALSE));
        else data_type_print_long_name(ifl, t);
    }
    if (data_type_is_constructor(t)) INDEX(" <i>any kind</i>");
}
void index_data_type_plural(int t) {
    if (type_IDs_table[t].plural_ref1 >= 0) {
        print_text_to_file(type_IDs_table[t].plural_ref1, type_IDs_table[t].plural_ref2,
            ifl);
        index_link(lw_array[type_IDs_table[t].plural_ref1].lw_source);
    } else {
        if (type_IDs_table[t].parsing_plural != NULL)
            INDEX("%s", vocab_get_exemplar(type_IDs_table[t].parsing_plural, FALSE));
        else data_type_print_long_plural(ifl, t);
    }
    if (data_type_is_constructor(t)) INDEX(" <i>any kind</i>");
}
```

The function index_data_type_name is called from 7/dim and 11/act.

Specifications 7/spec

Purpose

To create, manage and compare specifications.

Definitions

¶1. Conceptually, `specification` is the single most important data structure in Inform, unifying all of its concepts of data – specific or vague, singular or plural, now or in the past – in a single unambiguous representation. See the Introduction to this chapter for more on this.

The implementation is more down to earth, and looking at the structure definition is like looking at the side of a fancier Apple laptop – a long row of sockets, each different, some plugging into something specific, others general-purpose. As with laptop design, this `struct` has changed its sockets over the years, never being quite the same two builds running, yet always fulfilling the same basic function. And as with laptops, the pressure is always to get rid of what isn't needed. Very often the laptop is unplugged completely, or only has one or two cables connected, which makes all those unused sockets look wasteful. But all will be needed by someone, and we need to make sure there are enough sockets for any combination we will need to have fixed up at once.

Certainly the thinner this structure is, the better. Here is the current, sleek design, which ought to be branded Specification Pro. (Earlier models were nearly twice this size; sleek as the current form of SP may be, SPs still occupy around 8% of Inform's memory.) We have a single general-purpose socket, which like a USB port can fit a bewildering range of peripheral structures; a row of oddball proprietory sockets, fitting specific gadgets; and then a row of "arguments", which are like networking connections to other SPs.

```
define MAXIMUM_SPEC_ARGUMENTS 4          must be ≤ 7; TABLE_ENTRY_TY, the current record-holder, needs 4

typedef struct specification {
    int spec_packed_record;                                   see below: a packed bitmap
    int family_and_species;                                   UNKNOWN, or a family ID
    struct kind_of_value *associated_kov;                     NULL, or a kind of value
    int word_ref1, word_ref2;                                 the text thus interpreted
    general_pointer which_structure;                          can point to any Inform structure
    struct time_period *condition_tense;                      CONDITION_FMY: records the tense
    struct pcalc_prop *proposition;                           DESCRIPTION_SPC, TEST_PROPOSITION_SPC
    struct description_docket *docket;                        DESCRIPTION_SPC
    struct specification *arguments[MAXIMUM_SPEC_ARGUMENTS];
} specification;

int new_spec_count = 0, copied_spec_count = 0;                for the debugging log
```

The structure specification is private to this section.

¶2. We consolidate a large collection of flags, and small-integer values, into the "packed record" of the SP – a form of bitmap. A single SP can have any combination of the flags set or clear; can have any argument count; and can store a number n in the range $0 \le n < 65536$ for any *one* of several different purposes. When not stored, n reads as if it were -1.

define GENERIC_DATA_SPFLAG 0x00000001 *generic rather than actual data*
define ACTION_FOR_OTHER_SPFLAG 0x00000002 ACTION_SPC*: asking someone else to do this?*
define CONDITION_NEGATED_SPFLAG 0x00000004 CONDITION_FMY*: if set, negates the condition*
define RECORD_AS_SELF_SPFLAG 0x00000008 PROPERTY_VALUE_SPC*: record recipient as* self *when writing this*
define SELF_OBJECT_SPFLAG 0x00000010 CONSTANT_SPC-OBJECT_TY*: this represents* self *at run-time*
define NOTHING_OBJECT_SPFLAG 0x00000020 CONSTANT_SPC-OBJECT_TY *objects: this represents* nothing *at run-time*
define COERCED_SPFLAG 0x00000040 *warning: do not trust my value in a cache, I've been coerced!*

define BASE_OF_SPDATA_ID 0x00000100 *these bits hold a* *_SPDATA *constant showing how we use...*
define SPDATA_ID_MASK 0x00000f00
define BASE_OF_SPDATA 0x00001000 *...these bits*
define SPDATA_MASK 0x0ffff000

define NO_SPDATA 0 *the data portion of the bitmap isn't used*
define PHRASE_OPTION_SPDATA 1 TEST_PHRASE_OPTION_SPC*:* 2^i *where* i *is the option number,* $0 \le i < 16$
define QUANTITY_ENUMERATION_SPDATA 2 CONSTANT_SPC*: which one from an enumerated KOV*
define LOCAL_NUMBER_SPDATA 3 LOCAL_VARIABLE_SPC*: which of the locals on the current stack frame*
define GRAMMAR_TOKEN_SCORE_SPDATA 4 *score applied to this grammar token*

define BASE_OF_ARGC 0x10000000 *these bits hold the argument count, from 0 to* MAXIMUM_SPEC_ARGUMENTS
define ARGC_MASK 0x70000000

¶3. Species and their abilities. Different species use different combinations of the "sockets" in our structure, and we police that using the following flags:

define ASSOCIATED_KOV_SPCFLAG 0x00000001 *allowed to have an associated KOV*
define TENSE_SPCFLAG 0x00000002 *allowed to have a tense*
define PROPOSITION_SPCFLAG 0x00000004 *allowed to have a proposition*
define DOCKET_SPCFLAG 0x00000008 *allowed to have a docket*
define ARGUMENTS_SPCFLAG 0x00000010 *allowed to have one or more arguments*
define INVLIST_SPCFLAG 0x00000020 *allowed to have an invocation list*
define PHRASAL_SPCFLAG 0x00000040 *this species compiles to a function call*
define EVALUATING_SPCFLAG 0x00000080 *this species compiles to a value*

---

§**1. Creation.** There are two ways to create a SP structure – by allocating a new one in memory and initialising it, or by copying it from an existing one. Profiling shows that about 90% of SPs in memory at the end of Inform's run were made from new, and only 10% copied.

define SPECIES_MULTIPLIER 100

```
specification *spec_new(int family, int species) {
    specification *spec = CREATE(specification);
    spec->spec_packed_record = 0;
    spec->family_and_species = family + SPECIES_MULTIPLIER*species;
    spec->associated_kov = NULL;
    spec->word_ref1 = -1; spec->word_ref2 = -1;
    spec->which_structure = NULL_GENERAL_POINTER;
    spec->condition_tense = NULL;
```

```
    spec->proposition = NULL;
    spec->docket = NULL;
    new_spec_count++;
    return spec;
}
```

The function spec_new is called from 7/specv, 7/masp, 7/vasp, 7/stsp, 7/cosp and 7/cmsp.

§**2.** This routine could perhaps be defined as a macro, but I lack the steely nerves required.

```
specification *spec_copy(specification *spec) {
    specification *sts = CREATE(specification);
    *sts = *spec;
    copied_spec_count++;
    return sts;
}
```

The function spec_copy is called from 6/pform, 6/asp, 7/specv, 7/vasp, 7/cosp, 7/tc, 8/creat, 8/assem, 9/qty, 10/tab, 11/chron and 11/ap.

§**3. Coercion.** The process of transfiguring a given SP structure so that it belongs to a different species, or even a different family, is called "coercion". SPs which have been coerced are marked with a flag as a warning that what were previously duplicates of them may now not correspond with the original. Coercion is used as little as possible.

```
void spec_coerce_to(specification *spec, int new_family, int new_species) {
    spec->family_and_species = new_family + SPECIES_MULTIPLIER*new_species;
    spec_set_flag(spec, COERCED_SPFLAG);
}
```

The function spec_coerce_to is called from 7/vasp, 7/cosp and 7/cmsp.

§**4. Family and species.** Those are the *only* ways to set or alter the family or species – by creation, or subsequent coercion. Here are the ways to read them:

```
int species_is(specification *spec, int species) {
    if ((spec) && ((spec->family_and_species)/SPECIES_MULTIPLIER == species)) return TRUE;
    return FALSE;
}
int family_is(specification *spec, int family) {
    if ((spec) && ((spec->family_and_species)%SPECIES_MULTIPLIER == family)) return TRUE;
    return FALSE;
}
```

The function species_is is called from 2/prob2, 5/mlc, 6/term, 6/pform, 6/simp, 6/asp, 6/cind, 7/specv, 7/vasp, 7/stsp, 7/cosp, 7/tc, 8/refpt, 8/creat, 8/knowp, 9/prop, 9/pp, 9/inf, 10/list, 10/tab, 10/isin, 11/chron, 11/act, 11/ap, 11/av, 12/phud, 12/phtd, 12/cinv, 12/rb, 13/tfg, 13/gty and 13/gtok.
The function family_is is called from 5/aph, 6/simp, 6/defer, 7/stsp, 7/cosp, 7/tc, 8/refpt, 8/mass, 10/tab, 11/ap, 12/phrcd, 12/phtd, 12/cinv and 13/tfg.

§**5.** More explicitly:

```
int spec_get_species(specification *spec) {
    if (spec == NULL) return UNKNOWN;
    return (spec->family_and_species)/SPECIES_MULTIPLIER;
}
int spec_get_family(specification *spec) {
    if (spec == NULL) return UNKNOWN;
    return (spec->family_and_species)%SPECIES_MULTIPLIER;
}
```

The function spec_get_species is called from 7/tids, 7/vasp, 7/stsp, 7/cosp, 7/cmsp and 7/tc.
The function spec_get_family is called from 7/tids, 7/cfsp, 7/tc and 12/phtd.

§**6.** Different specifications have different abilities, some from their family membership, others their species membership.

```
int spec_test_ability(specification *spec, int f) {
    if (spec == NULL) return FALSE;
    if (type_ID_test_flag(spec_get_family(spec), f)) return TRUE;
    if (type_ID_test_flag(spec_get_species(spec), f)) return TRUE;
    return FALSE;
}
```

§**7. The unknown family and species.** Because they need to be given somewhere, and do not belong to any of the families, we might as well handle UNKNOWN specifications here:

```
int spec_is_UNKNOWN(specification *spec) {
    if (family_is(spec, UNKNOWN)) return TRUE;
    return FALSE;
}
specification *new_UNKNOWN_spec(void) {
    return spec_new(UNKNOWN, UNKNOWN);
}
void coerce_spec_to_UNKNOWN(specification *spec) {
    if (spec == NULL) internal_error("tried to invalidate null spec");
    spec_coerce_to(spec, UNKNOWN, UNKNOWN);
}
```

The function spec_is_UNKNOWN is called from 5/aph, 5/litp, 5/mlc, 6/tcpr, 7/ttts, 7/tc, 8/refpt, 9/qty, 9/scene, 9/prop, 9/pp, 10/tab, 10/eqns, 10/isin, 11/ap, 11/av, 12/phtd, 12/stv, 12/cinv and 13/gtok.
The function new_UNKNOWN_spec is called from 2/prob2, 5/mlc, 7/ttts, 7/specv, 8/refpt, 9/qty, 9/scene, 10/tab and 12/phtd.
The function coerce_spec_to_UNKNOWN is called from 5/mlc and 7/cosp.

§**8. Actual vs generic.** SPs are by default created as actual, since all SP-flags are initially clear, including `GENERIC_DATA_SPFLAG`. In practice, that's what most of them need to be. To create a generic specification, create an actual one and then use the routine below to make it generic instead.

```
void spec_make_actual(specification *spec) {
    spec_clear_flag(spec, GENERIC_DATA_SPFLAG);
}
void spec_make_generic(specification *spec) {
    spec_set_flag(spec, GENERIC_DATA_SPFLAG);
}
```

The function spec_make_actual is called from 7/cosp.
The function spec_make_generic is called from 7/specv, 7/masp, 7/vasp, 7/stsp and 7/cosp.

§**9.** And for testing:

```
int spec_is_actual(specification *spec) {
    return (spec_test_flag(spec, GENERIC_DATA_SPFLAG))?FALSE:TRUE;
}
int spec_is_generic(specification *spec) {
    return spec_test_flag(spec, GENERIC_DATA_SPFLAG);
}
```

The function spec_is_actual is called from 5/mlc, 7/vasp, 7/stsp and 7/tc.
The function spec_is_generic is called from 6/tcpr, 7/cfsp, 7/vasp, 7/stsp, 7/tc, 8/knowp, 10/tab and 11/ap.

§**10. Flags and data.** The following routines handle the flags crammed into the `spec_packed_record` field.

```
void spec_set_flag(specification *spec, int flag) {
    if (spec == NULL) internal_error("tried to set flag for null SP");
    spec->spec_packed_record = (spec->spec_packed_record) | flag;
}
void spec_clear_flag(specification *spec, int flag) {
    if (spec == NULL) internal_error("tried to clear flag for null SP");
    spec->spec_packed_record = (spec->spec_packed_record) & (~flag);
}
int spec_test_flag(specification *spec, int flag) {
    int f = (spec)?(spec->spec_packed_record):0;
    if (f & flag) return TRUE;
    return FALSE;
}
```

The function spec_set_flag is called from 5/mlc, 7/vasp, 7/cmsp, 7/tc and 11/chron.
The function spec_clear_flag is called from 5/mlc, 7/cmsp and 11/chron.
The function spec_test_flag is called from 5/mlc, 7/vasp, 7/stsp, 7/cosp, 7/cmsp, 7/tc and 11/chron.

§**11.** And similarly for the data portion of the packed record.

```
void spec_set_data(specification *spec, int purpose, int data) {
    if (spec == NULL) internal_error("tried to set data for null SP");
    if (data == -1) { purpose = NO_SPDATA; data = 0; }
    if ((data < 0) || (data >= 65536)) internal_error("tried to set data out of range");
    spec->spec_packed_record = ((spec->spec_packed_record) & (~(SPDATA_ID_MASK + SPDATA_MASK)))
        + BASE_OF_SPDATA_ID*purpose
        + BASE_OF_SPDATA*data;
}
int spec_get_data(specification *spec, int purpose) {
    if (spec == NULL) return -1;
    int there = ((spec->spec_packed_record) & SPDATA_ID_MASK)/BASE_OF_SPDATA_ID;
    if (there == NO_SPDATA) return -1;
    if (there == purpose) return ((spec->spec_packed_record) & SPDATA_MASK)/BASE_OF_SPDATA;
    internal_error("tried to fetch data with the wrong SPDATA ID");
    return -1;
}
```

The function spec_set_data is called from 7/stsp, 7/cosp, 9/qty and 13/gtok.
The function spec_get_data is called from 7/stsp, 7/cosp, 7/tc, 9/qty and 13/gty.

§**12. Arguments.** Recall that "arguments" are links out to other specification structures. The number of these currently attached is the "argc" (argument count) in the packed record.

```
int spec_get_argc(specification *spec) {
    if (spec == NULL) internal_error("tried to read argument of null SP");
    return ((spec->spec_packed_record) & ARGC_MASK)/BASE_OF_ARGC;
}
specification *spec_get_argument(specification *spec, int c) {
    if (spec == NULL) internal_error("tried to read argument of null SP");
    if ((c<0) || (c>=MAXIMUM_SPEC_ARGUMENTS)) internal_error("tried to read bad argument of SP");
    if (spec_test_ability(spec, ARGUMENTS_SPCFLAG) == FALSE)
        internal_error("tried to read argument of bad SP");
    if (c >= spec_get_argc(spec)) internal_error("tried to read missing argument of SP");
    return spec->arguments[c];
}
void spec_set_argument(specification *spec, int c, specification *arg) {
    if (spec == NULL) internal_error("tried to set argument of null SP");
    if ((c<0) || (c>=MAXIMUM_SPEC_ARGUMENTS)) internal_error("tried to set bad argument of SP");
    if (spec_test_ability(spec, ARGUMENTS_SPCFLAG) == FALSE)
        internal_error("tried to set argument of bad SP");
    if (c >= spec_get_argc(spec))
        spec->spec_packed_record = ((spec->spec_packed_record) & (~(ARGC_MASK))) + (c+1)*BASE_OF_ARGC;
    spec->arguments[c] = arg;
}
```

The function spec_get_argc is called from 6/simp, 6/defer, 6/cind, 7/stsp, 7/cosp, 7/cmsp, 7/tc and 11/ap.
The function spec_get_argument is called from 6/simp, 6/defer, 6/cind, 7/stsp, 7/cosp, 7/cmsp, 7/tc and 11/ap.
The function spec_set_argument is called from 5/mlc, 7/stsp, 7/cosp and 7/cmsp.

§**13. The associated KOV.** Some SPs have a kind of value associated with them: the following routines manage access to this.

```
kind_of_value *spec_get_kind_of_value(specification *spec) {
    if (spec_test_ability(spec, ASSOCIATED_KOV_SPCFLAG)) return spec->associated_kov;
    return NULL;
}
void spec_set_kind_of_value(specification *spec, kind_of_value *kov) {
    if (spec_test_ability(spec, ASSOCIATED_KOV_SPCFLAG)) spec->associated_kov = kov;
    else { LOG("$S\n", spec); internal_error("tried to set associated kov for wrong spec"); }
}
```

The function spec_get_kind_of_value is called from 2/prob2, 5/rel, 5/litp, 5/mlc, 6/term, 6/asp, 7/specv, 7/vasp, 7/stsp, 7/cosp, 7/tc, 8/refpt, 8/creat, 8/mass, 8/knowp, 9/prop, 9/pp, 9/provr, 9/inf, 10/tab, 10/eqns, 11/act, 11/av, 12/phtd, 12/cinv, 12/rb, 13/tfg, 13/gl, 13/gty and 13/gtok.
The function spec_set_kind_of_value is called from 7/masp, 7/vasp, 7/stsp, 7/tc, 9/qty, 10/bib, 11/ap, 12/phtd and 12/cinv.

§**14. The general structure field.**

```
general_pointer spec_get_structure_field(specification *spec) {
    if (spec == NULL) internal_error("tried to get structure for null spec");
    return spec->which_structure;
}
void spec_set_structure_field(specification *spec, general_pointer gp) {
    if (spec == NULL) internal_error("tried to set structure for null spec");
    spec->which_structure = gp;
}
```

The function spec_get_structure_field is called from 2/mem.
The function spec_set_structure_field is called from 2/mem.

§**15.** Perhaps the most interesting use of the general structure field is to point to an invocation list:

```
void spec_create_invocation_list(specification *spec) {
    if (spec_test_ability(spec, INVLIST_SPCFLAG) == FALSE) {
        LOG("SP: $X\n", spec); internal_error("can't create inv list for this spec");
    }
    ATTACH_TO_SPEC(spec, invocation_list, new_invocation_list());
}
void spec_set_invocation_list(specification *spec, invocation_list *invl) {
    if (spec_test_ability(spec, INVLIST_SPCFLAG) == FALSE) {
        LOG("SP: $X\n", spec); internal_error("can't create inv list for this spec");
    }
    ATTACH_TO_SPEC(spec, invocation_list, invl);
}
invocation_list *spec_invocation_list(specification *spec) {
    if (spec_test_ability(spec, INVLIST_SPCFLAG))
        return RETRIEVE_FROM_SPEC(spec, invocation_list);
    return NULL;
}
int spec_has_invocation_list(specification *spec) {
    if ((spec_test_ability(spec, INVLIST_SPCFLAG))
        && (VALID_POINTER_invocation_list(spec->which_structure))) return TRUE;
    return FALSE;
}
```

The function spec_create_invocation_list is called from 7/vasp, 7/cosp and 7/cmsp.
The function spec_set_invocation_list is called from 7/tc.
The function spec_invocation_list is called from 5/mlc, 6/cind, 7/vasp, 7/tc, 7/inv, 12/phtd, 12/cinv, 12/ambig and 12/cph.
The function spec_has_invocation_list is called from 7/tc, 7/inv and 12/cph.

§16. The attached proposition.

```
pcalc_prop *spec_get_proposition(specification *spec) {
    if (spec_test_ability(spec, PROPOSITION_SPCFLAG)) return spec->proposition;
    return NULL;
}
void spec_set_proposition(specification *spec, pcalc_prop *prop) {
    if (spec_test_ability(spec, PROPOSITION_SPCFLAG)) spec->proposition = prop;
    else { LOG("$S\n", spec); internal_error("tried to set proposition for wrong spec"); }
}
```

The function spec_get_proposition is called from 5/mlc, 6/pform, 6/treec, 6/defer, 7/vasp, 7/cosp, 7/tc, 8/refpt, 8/creat, 8/mass, 8/knowp, 10/tab, 11/chron, 11/ap, 12/phtd, 12/cinv, 13/gtok and 13/nft.
The function spec_set_proposition is called from 5/mlc, 7/vasp, 7/cosp and 11/chron.

§17. The attached docket.

```
description_docket *spec_get_docket(specification *spec) {
    if (spec_test_ability(spec, DOCKET_SPCFLAG)) return spec->docket;
/* if ((spec) && (spec->docket)) LOG("Surprising docket for $S\n", spec);
if (spec) return spec->docket; */
    return NULL;
}
void spec_set_docket(specification *spec, description_docket *dd) {
    if (spec_test_ability(spec, DOCKET_SPCFLAG)) spec->docket = dd;
    else { LOG("$S\n", spec); internal_error("tried to set docket for wrong spec"); }
}
```

The function spec_get_docket is called from 7/cosp.
The function spec_set_docket is called from 7/cosp.

§18. The attached tense.

```
time_period *spec_get_condition_tense(specification *spec) {
    if (spec_test_ability(spec, TENSE_SPCFLAG)) return spec->condition_tense;
    return NULL;
}
void spec_set_condition_tense(specification *spec, time_period *tp) {
    if (spec_test_ability(spec, TENSE_SPCFLAG)) spec->condition_tense = tp;
    else { LOG("$S\n", spec); internal_error("tried to set tense for wrong spec"); }
}
```

The function spec_get_condition_tense is called from 5/ml, 5/mlc and 7/cosp.
The function spec_set_condition_tense is called from 5/mlc, 7/cosp and 11/chron.

§**19. Evaluating and phrasal.** A specification is said to be "evaluating" if it compiles to an expression in I6 code.

```
int spec_is_evaluating(specification *spec) {
    return spec_test_ability(spec, EVALUATING_SPCFLAG);
}
kind_of_value *spec_evaluates_to(specification *spec) {
    if (spec == NULL) return NULL;
    switch(spec_get_family(spec)) {
        case COMMAND_FMY:   return kov_when_COMMAND_is_evaluated(spec);
        case CONDITION_FMY: return kov_when_CONDITION_is_evaluated(spec);
        case MATCHING_FMY:  return kov_when_MATCHING_is_evaluated(spec);
        case STORAGE_FMY:   return kov_when_STORAGE_is_evaluated(spec);
        case VALUE_FMY:     return kov_when_VALUE_is_evaluated(spec);
    }
    return NULL;
}
```

The function spec_is_evaluating is called from 7/tc, 8/knowp and 12/phtd.

The function spec_evaluates_to is called from 6/tcpr, 6/sch, 6/atoms, 6/defer, 6/cind, 7/cfsp, 7/vasp, 7/stsp, 7/cmsp, 7/tc, 8/creat, 8/knowp, 10/list, 10/tab, 10/eqns, 11/ap, 12/phtd, 12/cinv and 13/test.

§**20.** A specification is said to be "phrasal" if it compiles to a function call in I6 code (which may or may not return a value).

```
int spec_is_phrasal(specification *spec) {
    return spec_test_ability(spec, PHRASAL_SPCFLAG);
}
```

The function spec_is_phrasal is called from 6/cind, 8/refpt, 10/tab, 12/cinv and 13/tfg.

§**21. Pretty-printing specifications.** We need to be able to print legible forms of translations in order to produce good error messages, and also in order to describe phrases in the Index; those have to be English language forms.

```
void write_specification_out_in_English(specification *spec, char *text) {
    text[0] = 0;
    if (spec == NULL) { sprintf(text+strlen(text), "something unknown"); return; }
    switch(spec_get_family(spec)) {
        case COMMAND_FMY:   write_COMMAND_out_in_English(spec, text); return;
        case CONDITION_FMY: write_CONDITION_out_in_English(spec, text); return;
        case MATCHING_FMY:  write_MATCHING_out_in_English(spec, text); return;
        case STORAGE_FMY:   write_STORAGE_out_in_English(spec, text); return;
        case UNKNOWN:       sprintf(text+strlen(text), "something unrecognised"); return;
        case VALUE_FMY:     write_VALUE_out_in_English(spec, text); return;
    }
    internal_error("no such family");
}
```

The function write_specification_out_in_English is called from 2/prob2, 7/stsp and 12/phtd.

§**22.** The debugging log uses the concise shorthand for specifications described in the Introduction to this chapter. The concise form is a little formula for use in the middle of a line; the more flowery exhaustive form extends over and entirely occupies at least one and possibly more lines.

```
void log_specification_concisely(specification *spec) {
    log_specification_recursively(spec, FALSE);
    STREAM_FLUSH(dl);
}
void log_specification_exhaustively(specification *spec) {
    log_specification_recursively(spec, TRUE);
    STREAM_FLUSH(dl);
}
```

The function log_specification_concisely is called from 2/dl.
The function log_specification_exhaustively is called from 2/dl.

§**23.** And this is where it all happens:

```
void log_specification_recursively(specification *spec, int details) {
    if (spec == NULL) {
        LOG("<null type>");
        if (details) LOG("\n");
    } else if ((((pointer_sized_int) spec) >= -1000) && (((pointer_sized_int) spec) <= 1000)) {
        LOG("<corrupted? type %08x>", ((pointer_sized_int) spec));
        if (details) LOG("\n");
    } else {
        int family = spec_get_family(spec), species = spec_get_species(spec);
        if (type_ID_exists(family) == FALSE) {
            LOG("[Malformed:%d/%d]_TY", family, species);
            if (details) LOG("\n");
        } else {
            int w1 = spec->word_ref1, w2 = spec->word_ref2;
            if (spec_is_generic(spec)) LOG("(G)"); else LOG("(A)");
            if ((w1 >= 0) && (w2 >= w1) && (w2 < lexer_wordcount)) LOG("'$W'/", w1, w2);
            if ((spec_test_ability(spec, DOCKET_SPCFLAG)) && (spec_makes_callings(spec)))
                LOG("c/");
            LOG("$s/$s", family, species);
            if (spec_get_kind_of_value(spec)) LOG("-$u", spec_get_kind_of_value(spec));
            if (details) {
                switch(family) {
                    case COMMAND_FMY:   log_COMMAND_spec_details(spec); break;
                    case CONDITION_FMY: log_CONDITION_spec_details(spec); break;
                    case MATCHING_FMY:  log_MATCHING_spec_details(spec); break;
                    case STORAGE_FMY:   log_STORAGE_spec_details(spec); break;
                    case VALUE_FMY:     log_VALUE_spec_details(spec); break;
                }
                LOG("\n");
                int i;
                for (i=0; i<spec_get_argc(spec); i++) {
                    LOG("%d: ", i+1);
                    log_specification_recursively(spec_get_argument(spec, i), TRUE);
                }
                if (spec_has_invocation_list(spec))
                    log_invocation_list_in_detail(spec_invocation_list(spec));
```

```
            }
        }
    }
}
```

§24. Sorting. Some specifications are used to describe the applicability of rules and phrases, and since those must be sorted in order of how specific they are, we will need a way of telling when one specification is more specific than another. For instance, "Will Parker in the vineyard" beats "Will Parker" beats "a man" beats "a person" beats "an object" beats "a value".

The following is one of Inform's standardised comparison routines, which takes a pair of objects A, B and returns 1 if A makes a more specific description than B, 0 if they seem equally specific, or −1 if B makes a more specific description than A. This is transitive, and intended to be used in sorting algorithms.

```
int cco = 0;                                    comparison count: used to make the debugging log vaguely searchable
char *c_s_stage_law = "";                       name of the law being applied, which caused this to be called

int compare_specificity_of_spec(specification *spec1, specification *spec2) {
    LOGIF(SPECIFICITIES, "Law %s (test %d): comparing $S with $S\n",
        c_s_stage_law, cco++, spec1, spec2);
    ⟨Existence is itself something specific 25⟩;
    ⟨An actual specification is more specific than a generic one 26⟩;
    world_object *wo1 = spec_object_exactly_described_if_any(spec1);
    world_object *wo2 = spec_object_exactly_described_if_any(spec2);
    ⟨An exact object is more specific than a vague one 27⟩;
    if (wo1) ⟨Enclosing regions beat enclosed ones, and regions beat rooms 28⟩;
    int a = species_is(spec1, DESCRIPTION_SPC), b = species_is(spec2, DESCRIPTION_SPC);
    if ((a == TRUE) && (b == TRUE)) {                                   case 1: both are descriptions
        return compare_specificity_of_DESCRIPTIONs(spec1, spec2);
    } else if ((a == FALSE) && (b == FALSE)) {                          case 2: neither is a description
        ⟨Table entries are more specific than other non-descriptions 29⟩;
    } else {                                                            case 3: one is a description, the other isn't
        ⟨When is a description more specific than a non-description? 30⟩;
    }
    return 0;
}
```

The function compare_specificity_of_spec is called from 11/ap, 12/phrcd and 13/gty.

§25. Whether or not, as Bertrand Russell thought in 1894, existence is itself a good ("Great God in Boots! - the ontological argument is sound!"), a specification which exists is certainly more significant than one which does not; and there is nothing to choose between two specifications, neither of which exists.

A God who wears boots is an incongruous thought. Sandals, possibly. But maybe Russell meant the local Cambridge branch of Boots, the chemist's shop. At any rate he decided atheism was sounder still in 1896.

⟨Existence is itself something specific 25⟩ ≡

```
    if ((spec1 == NULL) && (spec2 != NULL)) return -1;
    if ((spec1 != NULL) && (spec2 == NULL)) return 1;
    if ((spec1 == NULL) && (spec2 == NULL)) return 0;
```

This code is used in §24.

§**26.** Hard to argue with this one: "34", for instance, is more specific than "a number". (We might quibble about whether or not "a number which equals 34" is really less specific than "34" – Inform says it is; but in fact it doesn't much matter either way.)

⟨An actual specification is more specific than a generic one 26⟩ ≡
```
if ((spec_is_actual(spec1)) && (spec_is_generic(spec2)))
    return 1;
if ((spec_is_generic(spec1)) && (spec_is_actual(spec2)))
    return -1;
```
This code is used in §24.

§**27.** For instance, "the open Marble Door" is more specific than "an open door" or even just "a door", even though the latter is linguistically simpler.

⟨An exact object is more specific than a vague one 27⟩ ≡
```
if ((wo1) && (wo2 == NULL)) return 1;
if ((wo1 == NULL) && (wo2)) return -1;
```
This code is used in §24.

§**28.** Suppose both specifications exactly describe objects, `wo1` and `wo2`, and all other considerations are equal. It's not quite true that one object is as good as another, because a region can be thought of as a set of rooms. (Without the following criterion, rules such as "After waiting in Russia" and "After waiting in Vladivostok Railway Station Waiting Room" would have equal status.)

⟨Enclosing regions beat enclosed ones, and regions beat rooms 28⟩ ≡
```
LOGIF(SPECIFICITIES, "Test %d: Comparing specificity of WOs $O and $O\n",
    cco, wo1, wo2);
int r1 = wo_of_kind(wo1, kind_room), r2 = wo_of_kind(wo2, kind_room);
int reg1 = wo_of_kind(wo1, kind_region), reg2 = wo_of_kind(wo2, kind_region);
if ((r1) && (reg2)) return 1;
if ((reg1) && (r2)) return -1;
if ((reg1) && (reg2)) {
    if (wo_in_wo(wo1, wo2)) return 1;
    if (wo_in_wo(wo2, wo1)) return -1;
}
```
This code is used in §24.

§**29.** Here neither specification is a `DESCRIPTION_SPC` or an actual object. For the most part, then, we're left with two specifications of about equal merit, and we don't choose between them. But in one case we do intervene: a table entry reference beats anything else left, so that "Instead of taking the magic key corresponding to Merlin in the Table of Arcana" is more specific than "Instead of taking the brass key". It's debateable whether this is a good convention, but users reported the previous absence of such a convention as a bug, which is usually telling.

⟨Table entries are more specific than other non-descriptions 29⟩ ≡
```
int t1 = species_is(spec1, TABLE_ENTRY_SPC);
int t2 = species_is(spec2, TABLE_ENTRY_SPC);
if ((t1 == TRUE) && (t2 == FALSE)) return 1;
if ((t1 == FALSE) && (t2 == TRUE)) return -1;
```
This code is used in §24.

§**30.** To explicate the following: a description of an exact object beats any non-description – thus "the open Marble Door" (a `DESCRIPTION_SPC`) beats "the Marble Door" (a `CONSTANT_SPC`). But any non-description beats a description which is vague about the object – thus "the Marble Door" beats "an open door", which is not news since rules above would enact that anyway, but also "the tallest door in the Castle" (a `PHRASE_TO_DECIDE_VALUE_SPC`) beats "an open door".

⟨When is a description more specific than a non-description? 30⟩ ≡

```
if (wo1) { if (a == TRUE) return 1; else return -1; }
else { if (a == TRUE) return -1; else return 1; }
```

This code is used in §24.

Text to Specifications 7/ttts

Purpose

Complete forms of parsing from excerpts of text to specifications.

7/ttts.§1-4 The cache; §5-7 The parser itself

Definitions

¶1. In this section we provide a routine, `parse_expression`, which turns a word range into a specification of its meaning.

This can parse six different forms of expression, though in fact three of these are variations of the same thing, so there are essentially only four different cases. The forms are identified by "expression context" or `*_EXPCON` numbers, as follows:

```
define VALUE_EXPCON 0
define CONDITION_EXPCON 1
define VOID_EXPCON 2
define TYPE_EXPCON 3
define DESCRIPTIVE_TYPE_EXPCON 4
define TYPE_OR_VALUE_EXPCON 5
define NUMBER_OF_EXPCONS 6
```

¶2. To explain this in brief:

(a) `VALUE_EXPCON` looks for source text which can be evaluated – a constant, a variable or other storage object, or a phrase to decide a value.

(b) `CONDITION_EXPCON` looks for a condition – anything legal after "if", in short. This includes sentence-like excerpts such as "six animals have been in the Stables".

(c) `VOID_EXPCON`, named after C's "void context", looks for a command – i.e., a "To..." phrase which does something rather than deciding something.

(d) `TYPE_EXPCON` is used where we expect to find the "type" of something – for instance, the kind of value to be stored in a variable, or the specification of a phrase argument.

(e) `DESCRIPTIVE_TYPE_EXPCON` is the same thing, with one difference: it allows nounless descriptions, such as "open opaque fixed in place", and to this end it treats bare adjective names as descriptions rather than values. If we have said "Colour is a kind of value. The colours are red, green and taupe. A thing has a colour.", then "green" is parsed by `DESCRIPTIVE_TYPE_EXPCON` as a description meaning "any thing which is green", but by `TYPE_EXPCON` and `VALUE_EXPCON` as a constant value of the KOV "colour".

(f) `TYPE_OR_VALUE_EXPCON` performs a `TYPE_EXPCON` first, and if that fails then it tries to parse a `VALUE_EXPCON` from the same text.

---

§**1. The cache.** The function `parse_expression` is called pretty frequently on overlapping or coinciding runs of text. Inform runs substantially faster if the results of parsing the most recent expressions are cached; so, for instance, if Inform parses the text in words 507 to 511 once, it need not do so again *in the same context.*

The cache takes the form of a modest ring buffer for each of the contexts:

```
define MAXIMUM_CACHE_SIZE 20          a Goldilocks value: too high slows us down, too low doesn't cache enough

typedef struct expression_cache {
```

```
    struct expression_cache_entry pe_cache[MAXIMUM_CACHE_SIZE];
    int pe_cache_size;                                  number of entries used, 0 to MAXIMUM_CACHE_SIZE
    int pe_cache_posn;                                  next write position, 0 to pe_cache_size minus 1
} expression_cache;

typedef struct expression_cache_entry {
    int word_ref1, word_ref2;                           the word range whose parsing this is
    struct specification *cached_pe_spec;               and the result (quite possibly UNKNOWN)
} expression_cache_entry;

expression_cache contextual_cache[NUMBER_OF_EXPCONS];

int parse_expression_called_before = FALSE;
```

The structure expression_cache is private to this section.
The structure expression_cache_entry is private to this section.

§**2.** The following seeks a previously cached answer:

⟨Check the expression cache to see if we already know the answer 2⟩ ≡

```
    expression_cache *ec = &(contextual_cache[context]);
    if (parse_expression_called_before == FALSE) {
        warn_expression_cache();                        this empties all the caches
        parse_expression_called_before = TRUE;
    }
    int i;
    for (i=0; i<ec->pe_cache_size; i++)
        if ((w1 == ec->pe_cache[i].word_ref1) && (w2 == ec->pe_cache[i].word_ref2))
            return ec->pe_cache[i].cached_pe_spec;
```

This code is used in §5.

§**3.** The cache expands until it reaches MAXIMUM_CACHE_SIZE; after that, entries are written in a position cycling through the ring. In either case it takes MAXIMUM_CACHE_SIZE further parses (not found in the cache) to overwrite the one we put down now.

⟨Write the newly discovered specification to the cache for future use 3⟩ ≡

```
    expression_cache *ec = &(contextual_cache[context]);
    ec->pe_cache[ec->pe_cache_posn].word_ref1 = w1;
    ec->pe_cache[ec->pe_cache_posn].word_ref2 = w2;
    ec->pe_cache[ec->pe_cache_posn].cached_pe_spec = spec;
    ec->pe_cache_posn++;
    if (ec->pe_cache_size < MAXIMUM_CACHE_SIZE) ec->pe_cache_size++;
    if (ec->pe_cache_posn == MAXIMUM_CACHE_SIZE) ec->pe_cache_posn = 0;
```

This code is used in §5.

§**4.** As with all caches, we have to be careful that the information does not fall out of date. There are two things which can go wrong: the specification pointed to by `cached_pe_spec` might be altered, perhaps as a result of the type-checker trying to force a round peg into a square hole; or the stock of Inform's defined names might change, so that the same text now has to be read differently.

The first problem can't be fixed here. It's tempting to try something like flagging specifications which have been altered, and then ensuring that the cache never serves up an altered result. But that fails for timing reasons – by the time the specification might be altered, pointers to it may exist in multiple data structures already, because the cache might have served it more than once by that time. (Not just a theoretical possibility – tests show that this does, albeit rarely, happen.) The brute force solution is to serve a copy of the cache entry, and thus never send out the same pointer twice. But this more than doubles the memory required to store specifications, which is unacceptable, and also slows Inform down, because allocating memory for all those copies is laborious. We therefore just have to be very careful about modifying specifications which have arisen from parsing.

The second problem is easier. We require other parts of Inform which make or unmake name definitions to warn us, by calling this routine. Definitions are made and unmade relatively rarely, so the performance hit is small.

```
void warn_expression_cache(void) {
    int i;
    for (i=0; i<NUMBER_OF_EXPCONS; i++) {
        contextual_cache[i].pe_cache_size = 0;
        contextual_cache[i].pe_cache_posn = 0;
    }
}
```

The function warn_expression_cache is called from 5/em and 12/phsf.

§**5. The parser itself.** With that out of the way, the actual routine is simple.

```
specification *parse_expression(int w1, int w2, int context) {
    if ((w1 < 0) || (w2 < w1)) return new_UNKNOWN_spec();
    if ((context < 0) || (context >= NUMBER_OF_EXPCONS))
        internal_error ("bad expression parsing context");
    ⟨Check the expression cache to see if we already know the answer 2⟩;
    meaning_list *ml = NULL;
    specification *spec = NULL;
    int pc = PARSED_SPCONTEXT;
    no_calls_to_SP_noun_phrase = 0;
    ⟨Ask the S-parser to produce a meaning list, then convert it 6⟩;
    ⟨Produce a problem message if the complexity threshold is reached 7⟩;
    if (spec->word_ref1 < 0) { spec->word_ref1 = w1; spec->word_ref2 = w2; }
    ⟨Write the newly discovered specification to the cache for future use 3⟩;
    if (!(spec_is_UNKNOWN(spec))) type_ID_observe(spec, pc);
    return spec;
}
```

The function parse_expression is called from 5/rel, 5/aph, 5/litp, 7/tc, 8/refpt, 9/scene, 9/prop, 9/pp, 10/list, 10/tab, 10/eqns, 10/bib, 10/isin, 11/act, 11/ap, 11/av, 12/phud, 12/phtd, 12/phsf, 12/stv, 12/cph, 12/def, 12/rb, 13/tfg, 13/gl, 13/gtok, 13/test and 14/i6t.

§**6.** The factors neatly into calls to the S-parser and the meaning-list converter, respectively, but note that TE-conversion requires `%9` to be set to the current word range in order for some of its problem messages to work.

⟨Ask the S-parser to produce a meaning list, then convert it 6⟩ ≡

```
CLEAR_MLC_BACKTRACE;
switch(context) {
    case VALUE_EXPCON:
        ml = SP_value(w1, w2);
        spec = VAL_subtree_to_spec(ml);
        break;
    case CONDITION_EXPCON:
        ml = SP_condition(w1, w2, TRUE);
        spec = COND_subtree_to_spec(ml);
        break;
    case VOID_EXPCON:
        ml = SP_command(w1, w2);
        spec = CMD_subtree_to_spec(ml);
        break;
    case TYPE_EXPCON:
        ml = SP_type_expression(w1, w2, FALSE);
        quote_words(9, w1, w2);
        spec = TE_subtree_to_spec(ml);
        pc = TYPE_PARSED_SPCONTEXT;
        break;
    case DESCRIPTIVE_TYPE_EXPCON:
        ml = SP_type_expression(w1, w2, TRUE);
        quote_words(9, w1, w2);
        spec = TE_subtree_to_spec(ml);
        pc = TYPE_PARSED_SPCONTEXT;
        break;
    case TYPE_OR_VALUE_EXPCON:
        ml = SP_type_expression(w1, w2, FALSE);
        quote_words(9, w1, w2);
        spec = TE_subtree_to_spec(ml);
        pc = TYPE_PARSED_SPCONTEXT;
        if (spec_is_UNKNOWN(spec)) {
            [[w1, w2 == the ... --> w1, w2]];
            ml = SP_value(w1, w2);
            spec = VAL_subtree_to_spec(ml);
            pc = PARSED_SPCONTEXT;
        }
        break;
}
CLEAR_MLC_BACKTRACE;
```

This code is used in §5.

§**7.** I don't believe the following problem message has been seen in the wild, but it was a useful precaution in the early days of testing the S-parser.

⟨Produce a problem message if the complexity threshold is reached 7⟩ ≡

```
if (no_calls_to_SP_noun_phrase >= S_PARSER_COMPLEXITY_THRESHOLD) {
    sentence_problem(_P_(C7OutOfControl),
        "this sentence seems to involve something too complicated to parse",
        "in that applying Inform's usual parsing techniques to it "
        "would take a very long time indeed to complete: since this "
        "tends to happen only with source text where some accident "
        "has occurred, for instance its punctuation having been "
        "stripped out, I'm reporting this as a Problem rather than "
        "wading blindly into it.");
}
```

This code is used in §5.

Specification Versions of Other Structures 7/specv

Purpose

To see how specifications correspond to other structures which they conceptually include.

Definitions

¶1. We have already seen in Chapter 5 that `meaning_list` structures are converted into specifications, but that isn't what we mean here: that's a permanent change (and the meaning lists are thrown away afterwards). Here we look at how specifications can represent the same data as other, more specific, structures: a type ID integer; a `kind_of_value`; a `quantity`; and a `world_object`.

---

§**1. Type ID numbers.** Here the S-parser supplies us with the ID of what might refer to something as broad as a family, say "condition", or as narrow as a constant value of a particular KOV, say "number". We have to create the appropriate specification to refer to anything falling under this reference. (This is the only place in Inform where specifications are created other than via constructor routines which explicitly know what species they are making.)

```
specification *new_generic_type_from_ID(int ID_number) {
    if (ID_number == UNKNOWN) return new_UNKNOWN_spec();
    if (type_ID_is_data_type(ID_number))
        return new_generic_CONSTANT_type(kova(ID_number));
    int family = UNKNOWN, species = UNKNOWN;
    if (type_ID_is_family_ID(ID_number)) {
        family = ID_number;
        species = UNKNOWN;
    } else {
        family = type_ID_get_family_of_species(ID_number);
        species = ID_number;
        if (family == UNKNOWN) {
            LOG("ID number is %d = $s\n", ID_number, ID_number);
            internal_error("no permitted family for this species");
        }
    }
    specification *spec = spec_new(family, species);
    spec_make_generic(spec);
    return spec;
}
```

The function new_generic_type_from_ID is called from 5/ml.

§**2. How KOVs are embedded in the specification hierarchy.** KOVs form a sort of sub-hierarchy of the larger hierarchy of specifications.

Every KOV represents the concept of being a value of that kind – for instance, `kova(TEXT_TY)` represents "being a piece of text". The equivalent idea among specifications is a generic constant value of that kind: for instance,

`(G)VALUE_FMY/CONSTANT_SPC-text-KOV`

The following routine makes the correspondence: given K, it returns a specification for a generic constant K-value.

```
specification *kov_as_spec(kind_of_value *kov) {
    if (kov == NULL) return NULL;
    return new_generic_CONSTANT_type(kov);
}
```

The function kov_as_spec is called from 7/cmsp, 9/pp and 10/tab.

§**3. Specifications from quantities.** The `quantity` structure indicates a named value, which might be either a variable or a constant – this means it can give rise to a specification in either of two different families, so we handle the conversion here.

```
specification *new_QUANTITY_spec(quantity *q) {
    specification *spec;
    if (q == NULL) internal_error("new_QUANTITY_spec on null quantity");
    if (qty_is_a_variable(q)) {
        spec = new_actual_NONLOCAL_VARIABLE_type(q);
    } else {
        if (is_kova(qty_kind_of_value(q), SCENE_TY))
            spec = spec_copy(qty_get_initial_value(q));
        else {
            spec = new_actual_CONSTANT_spec(qty_kind_of_value(q));
            ATTACH_TO_SPEC(spec, quantity, q);
        }
        spec->word_ref1 = q->word_ref1; spec->word_ref2 = q->word_ref2;
    }
    return spec;
}
quantity *spec_get_constant_quantity_if_any(specification *spec) {
    if (spec_is_actual_CONSTANT(spec)) {
        kind_of_value *kov = spec_get_kind_of_value(spec);
        if (is_kova(kov, SCENE_TY))
            return scene_quantity(SCENE_spec_to_scene(spec));
        if (kov_is_an_enumeration(kov))
            return RETRIEVE_FROM_SPEC(spec, quantity);
    }
    return NULL;
}
```

The function new_QUANTITY_spec is called from 5/tandv, 5/mlc, 6/term, 6/simp, 6/defer, 8/refpt, 9/qty, 9/pp, 10/tab, 11/ap, 13/tfg and 13/nft.

The function spec_get_constant_quantity_if_any is called from 6/pform, 6/equal, 7/vasp, 7/tc, 8/mass, 9/scene, 9/inf, 9/cot, 12/phud, 12/phrcd and 12/cinv.

§**4. Exact and vague object descriptions.** Specifications which talk about objects lie in two different families: "an animal" or "Lassie" are in the `CONSTANT_SPC` species of the `VALUE_FMY` family, with KOV "object"; but "an open door which is in a lighted room" (say) is in the `DESCRIPTION_SPC` species of the `CONDITION_FMY` family. It's convenient to have routines handling these two cases jointly:

```
int spec_describes_an_object_vaguely_or_exactly(specification *spec) {
    if (spec == NULL) return FALSE;
    if (species_is(spec, DESCRIPTION_SPC)) return TRUE;
    if (spec_is_CONSTANT_of_kova(spec, OBJECT_TY)) return TRUE;
    return FALSE;
}

world_object *spec_object_exactly_described_if_any(specification *spec) {
    if (spec == NULL) return NULL;
    if (species_is(spec, DESCRIPTION_SPC)) return spec_get_described_object(spec);
    if (spec_is_actual_CONSTANT_of_kova(spec, OBJECT_TY)) {
        if (spec_is_nothing_object_constant(spec)) return NULL;
        return OBJECT_spec_to_world_object(spec);
    }
    return NULL;
}
```

The function spec_describes_an_object_vaguely_or_exactly is called from 5/aph, 11/ap and 13/gtok.

The function spec_object_exactly_described_if_any is called from 6/simp, 7/spec, 10/tab, 11/ap, 13/tfg and 13/gtok.

Compiling from Specifications 7/cfsp

Purpose

To compile specifications into Inform 6 values, conditions or void expressions.

Definitions

¶1. In a more traditional compiler, the code-generator would be something of a landmark – one of the three or four most important stations. Here it's something of an anticlimax, partly because traditional "code" – values and statements – are only a small part of the I6 we have to generate, which also includes object and class definitions, grammar, and so on.

Still, this is the key point where the actual rather than generic specifications – phrases to do something, or to decide things; constants; variables; conditions – finally convert into I6 code.

¶2. For the most part this is "modeless" – that is, the I6 code generated by a specification does not depend on any context. But not entirely so, and we have a small set of "C-modes", each of which slightly alters the result to fit some particular need.

The rule is that any part of Inform needing to do something in a specific mode should place that operation within a pair of `BEGIN_COMPILATION_MODE` and `END_COMPILATION_MODE` macros, in such a way that execution always passes from one to the other. Within those bookends, it can use either the enter or exit macros to switch a particular mode on or off.

```
define BEGIN_COMPILATION_MODE
    int status_quo_ante = compilation_mode;
define COMPILATION_MODE_ENTER(mode)
    compilation_mode |= mode;
define COMPILATION_MODE_EXIT(mode)
    compilation_mode &= (~mode);
define END_COMPILATION_MODE
    compilation_mode = status_quo_ante;
define TEST_COMPILATION_MODE(mode)
    (compilation_mode & mode)

define DEREFERENCE_POINTERS_CMODE     0x00000001    make an independent copy of the result if on the heap
define INSIDE_RESOLVER_CMODE          0x00000002    compiling inside an I6 ambiguity-resolving routine
define BLOCK_CONSTANT_CMODE           0x00000004    compiling a pointer to a constant value on the heap
define DO_NOT_CREATE_LOCAL_VARS_CMODE 0x00000008    some phrases, like "let", create local variables
define IMPLY_NEWLINES_IN_SAY_CMODE    0x00000010    true except in text routines
define PERMIT_LOCALS_IN_TEXT_CMODE    0x00000020    unless casting to indexed text
define COMPILE_TEXT_TO_XML_CMODE      0x00000040    use XML escapes and UTF-8 encoding
define TRUNCATE_TEXT_CMODE            0x00000080    into a plausible filename length

int compilation_mode = DEREFERENCE_POINTERS_CMODE + IMPLY_NEWLINES_IN_SAY_CMODE;    default
```

¶3. These modes are all explained where they are used. The one used right here is `DEREFERENCE_POINTERS_CMODE`. This applies only when compiling a specification which generates a pointer value – an I6 value which is a pointer to a larger block of data on the heap, such as a list or indexed text.

Inform presents such values to the end user exactly as if they are non-pointer values. It must always be careful to ensure that there are never two different I7 values each holding pointers to the same block of data, because then changing one would also change the other. So we ordinarily need to make a copy of any block of data produced as a value; this is called "dereferencing".

But there are some circumstances – initialising entries in an Inform 6 array, for instance – where we don't want to do this, and indeed can't, because the code to handle dereferencing is invalid as an Inform 6 constant. The mode therefore exists as a way of temporarily turning off dereferencing – by default, it is always on.

---

§**1.** The outer shell here has two purposes. One is to copy the specification onto the local stack frame and then compile that copy – useful since compilation may alter its contents. The other purpose, and this is not to be dismissed lightly, is to ensure correct indentation in the log when `compile_TS_primitive` exits unexpectedly, for instance due to a problem. Correct indentation in the log is much more helpful than might be guessed.

```
void spec_compile(OUTPUT_STREAM, specification *spec) {
    LOGIF(EXPRESSIONS, "Compiling: $S\n", spec);
    if (spec_is_generic(spec)) internal_error("compiled a generic specification");
    STREAM_INDENT(dl);
    specification breakable_copy = *spec;
    spec_compile_primitive(OUT, &breakable_copy);
    STREAM_OUTDENT(dl);
}
```

The function spec_compile is called from 6/defer, 6/cind, 7/stsp, 7/cosp, 7/cmsp, 9/qty, 9/scene, 9/inf, 9/cot, 10/list, 10/tab, 10/eqns, 10/bib, 11/chron, 11/ap, 11/av, 12/phrcd, 12/phsf, 12/cinv, 12/cph, 12/def, 12/br, 13/gl, 13/gty, 13/gpr, 13/test and 14/i6t.

§**2.** So this is where the compilation is done, or rather, delegated:

```
void spec_compile_primitive(OUTPUT_STREAM, specification *spec) {
    type_ID_observe(spec, COMPILED_SPCONTEXT);
    char *suffix = "";
    if ((TEST_COMPILATION_MODE(DEREFERENCE_POINTERS_CMODE)) &&
        (TEST_COMPILATION_MODE(INSIDE_RESOLVER_CMODE) == FALSE)) {
        kind_of_value *kov = spec_evaluates_to(spec);
        if ((kov) && (kov_uses_pointer_values(kov))) {
            pointer_allocation *pall = phsf_add_allocation(kov, NULL);
            WRITE("BlkValueCopy(%s, ", pall_get_local_reference(pall));
            suffix = ")";
        }
    }
    switch(spec_get_family(spec)) {
        case COMMAND_FMY:   compile_COMMAND_spec(OUT, spec); break;
        case CONDITION_FMY: compile_CONDITION_spec(OUT, spec); break;
        case MATCHING_FMY:  compile_MATCHING_spec(OUT, spec); break;
        case STORAGE_FMY:   compile_STORAGE_spec(OUT, spec); break;
        case UNKNOWN:       break;                                  for error recovery
        case VALUE_FMY:     compile_VALUE_spec(OUT, spec); break;
    }
    WRITE("%s", suffix);
}
```

MATCHING Specifications 7/masp

Purpose

Documentation on and functions handling specifications which fall into the MATCHING family.

§1. Creation. The only MATCHING species is `NEW_LOCAL_VARIABLE_NAME_SPC`, used only for a generic SP which matches text which either has no meaning, or refers to a globally defined excerpt which a local variable name is allowed to temporarily override. For instance, this is the specification of the parameter in:

> To prognosticate about (V - nonexisting number variable): ...

As in this case, such a SP can also have an associated KOV (here it is `NUMBER_TY`, of course). On a successful match with this token in type-checking, a new local variable is created with the name matched, and given the KOV supplied.

```
void create_MATCHING_species(void) {
    type_ID_set_description(MATCHING_FMY, "a miscellaneous type used for matching only");
    type_ID_set_source_name(MATCHING_FMY, "MATCHING_FMY");
    type_ID_permit_pair(MATCHING_FMY, NEW_LOCAL_VARIABLE_NAME_SPC,
        PARSED_SPCONTEXT + TYPE_PARSED_SPCONTEXT + TYPE_EXPECTED_SPCONTEXT + TYPE_FOUND_SPCONTEXT);
    type_ID_set_description(NEW_LOCAL_VARIABLE_NAME_SPC, "a name not so far used");
    type_ID_set_source_name(NEW_LOCAL_VARIABLE_NAME_SPC, "NEW_LOCAL_VARIABLE_NAME_SPC");
    type_ID_set_flag(NEW_LOCAL_VARIABLE_NAME_SPC, ASSOCIATED_KOV_SPCFLAG);
}
specification *new_NEW_LOCAL_VARIABLE_NAME_spec(kind_of_value *kov) {
    specification *spec = spec_new(MATCHING_FMY, NEW_LOCAL_VARIABLE_NAME_SPC);
    if (kov) spec_set_kind_of_value(spec, kov);
    spec_make_generic(spec);
    return spec;
}
```

The function create_MATCHING_species is called from 7/tids.

The function new_NEW_LOCAL_VARIABLE_NAME_spec is called from 5/mlc.

§2. Pretty-printing. There is nothing very specific to say about them:

```
void write_MATCHING_out_in_English(specification *spec, char *text) {
    sprintf(text+strlen(text), "a name not so far used");
}
void log_MATCHING_spec_details(specification *spec) {
}
```

The function write_MATCHING_out_in_English is called from 7/spec.

The function log_MATCHING_spec_details is called from 7/spec.

§**3. Compilation.** Since `MATCHING` family species are purely for type-checking, they are never actual, always generic; so they do not evaluate, and cannot be compiled.

```
kind_of_value *kov_when_MATCHING_is_evaluated(specification *spec) {
    return NULL;
}
void compile_MATCHING_spec(OUTPUT_STREAM, specification *spec_found) {
    internal_error("MATCHING specifications cannot be compiled");
}
```

The function kov_when_MATCHING_is_evaluated is called from 7/spec.

The function compile_MATCHING_spec is called from 7/cfsp.

VALUE Specifications 7/vasp

Purpose

Documentation on and functions handling specifications which fall into the VALUE family.

7/vasp.§1-5 Creation; §6-9 Coercion; §10-15 Testing; §16-17 Pretty-printing; §18-28 Compilation

---

Template interpreter commands

```
28  {-callv:create_block_constants}
```

Definitions

¶1. The `VALUE` family represents what in other programming languages would be called "lvalues" rather than "rvalues": things which evaluate, but which cannot be the target of assignments. "Rvalues", which both evaluate and can also be assigned to, make up the `STORAGE` family.

¶2. "Block" (or sometimes "pointer") values are those which, at run-time, are stored in blocks of data on the heap, and represented by pointers to these blocks. That makes constants harder to compile: whereas compiling "34" means writing a single word, compiling "$\{1, 2, 4\}$" *means writing a pointer and also remembering to compile the list conte*

```
typedef struct stored_block_value {
    struct specification *stored_constant;          the block value we'll need to store
    int size_of_block;                              number of bytes on the heap to allocate
    MEMORY_MANAGEMENT
} stored_block_value;
```

The structure stored_block_value is private to this section.

---

§**1. Creation.** The `CONSTANT_SPC` species include boths literals – values lexically recognised at once as being constants of a given KOV, in the way that "103" is recognised as a `NUMBER_TY` and that "21 kg" might be recognised as a value of a unit of weight – and also names for constants which need to be parsed from the registered excerpts: for instance, "green" in an enumerated KOV whose values are "red", "green" and "blue". Such SPs use the associated KOV to indicate what kind of value they have (or are expected to match against).

§**2.** PHRASE_TO_DECIDE_VALUE_SPC specifications carry an attached invocation list, as all phrase specifications do.

```
void create_VALUE_species(void) {
    type_ID_set_description(VALUE_FMY, "a value quoted or calculated but not stored");
    type_ID_set_source_name(VALUE_FMY, "VALUE_FMY");
    type_ID_set_flag(VALUE_FMY, EVALUATING_SPCFLAG);
    type_ID_permit_pair(VALUE_FMY, CONSTANT_SPC,
        TYPE_PARSED_SPCONTEXT + PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(CONSTANT_SPC, "a value");
    type_ID_set_source_name(CONSTANT_SPC, "CONSTANT_SPC");
    type_ID_set_flag(CONSTANT_SPC, ASSOCIATED_KOV_SPCFLAG);
    type_ID_set_flag(CONSTANT_SPC,
        DOCKET_SPCFLAG + PROPOSITION_SPCFLAG);                    for DESCRIPTION_TY constants only
    type_ID_permit_pair(VALUE_FMY, PHRASE_TO_DECIDE_VALUE_SPC,
        PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT + TYPE_EXPECTED_SPCONTEXT +
        COMPILED_SPCONTEXT);
    type_ID_set_description(PHRASE_TO_DECIDE_VALUE_SPC, "a phrase to decide a value");
    type_ID_set_source_name(PHRASE_TO_DECIDE_VALUE_SPC, "PHRASE_TO_DECIDE_VALUE_SPC");
    type_ID_set_flag(PHRASE_TO_DECIDE_VALUE_SPC, PHRASAL_SPCFLAG + INVLIST_SPCFLAG);
}
```

The function create_VALUE_species is called from 7/tids.

§**3.** In the case of actual CONSTANT_SPC specifications, a pointer to some structure may be attached, with the choice of structure depending on KOV. For instance, a constant of TABLE_TY carries a pointer to the relevant table structure, but a constant NUMBER_TY has nothing attached.

Constants where no pointer is attached can be straightforwardly be made with the following:

```
specification *new_actual_CONSTANT_spec(kind_of_value *kov) {
    specification *spec = spec_new(VALUE_FMY, CONSTANT_SPC);
    spec_set_kind_of_value(spec, kov);
    return spec;
}
specification *new_generic_CONSTANT_type(kind_of_value *kov) {
    specification *spec = new_actual_CONSTANT_spec(kov);
    spec_make_generic(spec);
    return spec;
}
```

The function new_actual_CONSTANT_spec is called from 2/mem, 5/lit, 7/specv, 8/sob, 8/knowp, 9/madj, 11/ap and 12/phtd.
The function new_generic_CONSTANT_type is called from 2/prob2, 5/ml, 6/asp, 7/specv, 7/stsp, 7/tc, 8/refpt, 8/creat, 8/mass, 8/knowp, 9/pp, 10/tab, 10/eqns, 11/act, 11/ap, 11/av, 12/rb and 13/gtok.

§**4.** Constants with pointers attached are made with the macro-defined routines defined way back in "Memory", with names like `table_to_TABLE_spec`, which take one argument – a pointer to the relevant data structure, which must be the right type and non-`NULL` – and returns a new actual constant of the corresponding KOV and with this pointer attached.

That works very well, except for one quirk. There are two pseudo-objects for which no pointers to `world_object` can exist: "self" and "nothing". These are marked out with special flags:

```
specification *new_self_object_constant(void) {
    specification *spec = new_actual_CONSTANT_spec(kova(OBJECT_TY));
    spec_set_flag(spec, SELF_OBJECT_SPFLAG);
    return spec;
}
specification *new_nothing_object_constant(void) {
    specification *spec = new_actual_CONSTANT_spec(kova(OBJECT_TY));
    spec_set_flag(spec, NOTHING_OBJECT_SPFLAG);
    return spec;
}
```

The function new_self_object_constant is called from 6/sconv and 7/tc.
The function new_nothing_object_constant is called from 5/mlc and 6/treec.

§**5.** The following makes a new phrase-to-decide-value, with an empty invocation list ready to be filled in.

```
specification *new_PHRASE_TO_DECIDE_VALUE_spec(void) {
    specification *spec = spec_new(VALUE_FMY, PHRASE_TO_DECIDE_VALUE_SPC);
    spec_create_invocation_list(spec);
    return spec;
}
```

The function new_PHRASE_TO_DECIDE_VALUE_spec is called from 5/mlc.

§**6. Coercion.** The need for coercions is usually a sign of some subtle ambiguity in how the same data might be specified, and the following demonstrate that. First, when a description such as "people holding animals" is treated as a constant value to be passed as a phrase parameter, it has to migrate from the `CONDITION` to the `VALUE` family. It carries its docket and/or proposition with it.

```
int coerce_DESCRIPTION_to_VALUE(specification *spec, int objects) {
    if (species_is(spec, DESCRIPTION_SPC) == FALSE)
        internal_error("can't coerce non-DESCRIPTION");
    pcalc_prop *prop = spec_get_proposition(spec);
    if (prop) {
        prop = prop_copy(prop);
        prop = prop_trim_universal_quantifier(prop);
        if (vars_number_free(prop) != 1) return FALSE;
        spec_set_proposition(spec, prop);
    }
    spec_coerce_to(spec, VALUE_FMY, CONSTANT_SPC);
    if (objects) spec_set_kind_of_value(spec, kova(OBJECT_DESCRIPTION_TY));
    else spec_set_kind_of_value(spec, kova(VALUE_DESCRIPTION_TY));
    return TRUE;
}
```

The function coerce_DESCRIPTION_to_VALUE is called from 7/tc and 12/phrcd.

§**7.** Much the same can be said of action patterns:

```
void coerce_TEST_ACTION_to_STORED_ACTION(specification *spec) {
    if (species_is(spec, TEST_ACTION_SPC) == FALSE)
        internal_error("can't coerce non-TEST_ACTION_SPC");
    spec_coerce_to(spec, VALUE_FMY, CONSTANT_SPC);
    spec_set_kind_of_value(spec, kova(STORED_ACTION_TY));
}
```

The function coerce_TEST_ACTION_to_STORED_ACTION is called from 8/refpt and 10/tab.

§**8.** The following is used in order to make it possible to test whether stored actions match a given description. For instance, the "is" in:

if the current action is taking something...

compares a stored action ("current action" is a phrase to decide a stored action) with "taking something", which needs to be a value in order for it to be a noun phrase. So it is converted to a constant `DESCRIPTION_OF_ACTION_TY` to make this viable.

```
void coerce_TEST_ACTION_to_DESCRIPTION_OF_ACTION(specification *spec) {
    if (species_is(spec, TEST_ACTION_SPC) == FALSE)
        internal_error("can't coerce non-TEST_ACTION_SPC");
    spec_coerce_to(spec, VALUE_FMY, CONSTANT_SPC);
    spec_set_kind_of_value(spec, kova(DESCRIPTION_OF_ACTION_TY));
}
```

The function coerce_TEST_ACTION_to_DESCRIPTION_OF_ACTION is called from 6/simp.

§**9.** Lastly, the notation in the source for text to be printed is the same as that to be matched against typed commands, but these have very different representations at run-time. The following is used when we've guessed wrongly which we're going to want:

```
void coerce_UNDERSTANDING_to_TEXT(specification *spec) {
    if (species_is(spec, CONSTANT_SPC) == FALSE)
        internal_error("can't coerce non-CONSTANT_SPC");
    spec_set_kind_of_value(spec, kova(TEXT_TY));
}
```

The function coerce_UNDERSTANDING_to_TEXT is called from 7/cmsp.

§**10. Testing.** The following provide convenient shorthands for testing whether a given specification is a constant.

```
int spec_is_actual_CONSTANT(specification *spec) {
    if ((species_is(spec, CONSTANT_SPC)) && (spec_is_actual(spec))) return TRUE;
    return FALSE;
}
int spec_is_generic_CONSTANT(specification *spec) {
    if ((species_is(spec, CONSTANT_SPC)) && (spec_is_generic(spec))) return TRUE;
    return FALSE;
}
```

The function spec_is_actual_CONSTANT is called from 5/aph, 5/litp, 5/mlc, 6/term, 7/specv, 7/tc, 8/mass, 8/knowp, 10/tab, 10/eqns, 12/phtd and 12/rb.

The function spec_is_generic_CONSTANT is called from 5/rel, 5/litp, 5/mlc, 7/cosp, 7/tc, 8/refpt, 8/creat, 8/mass, 8/knowp, 9/prop, 9/pp, 9/provr, 9/inf, 10/tab, 10/eqns, 11/act, 11/ap, 11/av, 12/phtd, 12/cinv, 13/tfg, 13/gl, 13/gty and 13/gtok.

§**11.** And now versions which require a particular KOV, too.

```
int spec_is_CONSTANT_of_kova(specification *spec, int bt) {
    if ((species_is(spec, CONSTANT_SPC)) && (is_kova(spec_get_kind_of_value(spec), bt)))
        return TRUE;
    return FALSE;
}
int spec_is_actual_CONSTANT_of_kova(specification *spec, int bt) {
    if ((species_is(spec, CONSTANT_SPC)) && (spec_is_actual(spec)) &&
        (is_kova(spec_get_kind_of_value(spec), bt))) return TRUE;
    return FALSE;
}
int spec_is_generic_CONSTANT_of_kova(specification *spec, int bt) {
    if ((species_is(spec, CONSTANT_SPC)) && (spec_is_generic(spec)) &&
        (is_kova(spec_get_kind_of_value(spec), bt))) return TRUE;
    return FALSE;
}
```

The function spec_is_CONSTANT_of_kova is called from 2/prob2, 6/pform, 6/sconv, 7/specv, 7/stsp, 7/cmsp, 7/tc, 8/mass, 10/tab, 11/ap, 12/phtd, 12/cinv and 13/gtok.
The function spec_is_actual_CONSTANT_of_kova is called from 2/mem, 6/simp, 7/specv, 7/tc, 9/prop, 9/pp and 10/isin.
The function spec_is_generic_CONSTANT_of_kova is called from 7/tc and 12/phtd.

§**12.** To go back to the self/nothing anomalies (that really could be an episode title from *The Big Bang Theory*),

```
int spec_is_nothing_object_constant(specification *spec) {
    if (spec_test_flag(spec, NOTHING_OBJECT_SPFLAG)) return TRUE;
    return FALSE;
}
int spec_is_self_object_constant(specification *spec) {
    if (spec_test_flag(spec, SELF_OBJECT_SPFLAG)) return TRUE;
    return FALSE;
}
world_object *wo_of_CONSTANT_OBJECT_if_any(specification *spec) {
    if (spec_is_actual_CONSTANT_of_kova(spec, OBJECT_TY)) {
        if (spec_test_flag(spec, SELF_OBJECT_SPFLAG)) return NULL;
        if (spec_test_flag(spec, NOTHING_OBJECT_SPFLAG)) return NULL;
        return OBJECT_spec_to_world_object(spec);
    }
    return NULL;
}
```

The function spec_is_nothing_object_constant is called from 6/vars, 6/simp, 7/specv, 7/tc and 8/knowp.
The function spec_is_self_object_constant is called from 7/stsp.
The function wo_of_CONSTANT_OBJECT_if_any is called from 5/aph, 5/mlc, 6/term, 6/asp, 7/tc, 8/refpt, 9/qty and 11/ap.

§**13.** A similar convenience for specifications which might or might not refer to property names:

```
property_name *spec_get_property_name_if_any(specification *spec) {
    if (spec_is_actual_CONSTANT_of_kova(spec, PROPERTY_TY))
        return PROPERTY_spec_to_property_name(spec);
    return NULL;
}
```

The function spec_get_property_name_if_any is called from 7/stsp, 7/tc, 9/provr and 12/cinv.

§**14.** And also for finding the integer value of a literal integer, something we surprisingly seldom need to do. Here there's no pointer attached to the specification, and indeed it doesn't even store the integer in question; it simply reparses the text when needed, since parsing a literal is quick.

```
int value_of_NUMBER_type(specification *spec) {
    if (spec->word_ref1 < 0)
        internal_error("Text no longer available for CONSTANT compilation");
    if (is_kova(is_a_literal(spec->word_ref1, spec->word_ref2),
        NUMBER_TY) == FALSE) {
        LOG("SP: $S\n", spec);
        internal_error("Type anomaly for CONSTANT compilation");
    }
    return last_literal_evaluated;
}
```

The function value_of_NUMBER_type is called from 10/eqns.

§**15.** Our most elaborate test is a finicky one, checking if two constant values are equal at compile time – which is needed when seeing how to mesh table continuations together, and in rare cases to help the typechecker. This doesn't need to be especially rapid.

```
define COMPARE_CONSTANTS(DATA, STRUCTURE)
    if (is_kova(kov1, DATA##_TY)) {
        STRUCTURE *x1 = DATA##_spec_to_##STRUCTURE(spec1);
        STRUCTURE *x2 = DATA##_spec_to_##STRUCTURE(spec2);
        if (x1 == x2) return TRUE;
        return FALSE;
    }

int spec_compare_CONSTANT(specification *spec1, specification *spec2) {
    if (spec_is_actual_CONSTANT(spec1) == FALSE) return FALSE;
    if (spec_is_actual_CONSTANT(spec2) == FALSE) return FALSE;
    kind_of_value *kov1 = spec_get_kind_of_value(spec1);
    kind_of_value *kov2 = spec_get_kind_of_value(spec2);
    if (kov_compare(kov1, kov2) == FALSE) return FALSE;
    switch (kov_get_constant_compilation_method(kov1)) {
        case LITERAL_CCM: {
            int v1, v2;
            is_a_literal(spec1->word_ref1, spec1->word_ref2);
            v1 = last_literal_evaluated;
            is_a_literal(spec2->word_ref1, spec2->word_ref2);
            v2 = last_literal_evaluated;
            if (v1 == v2) return TRUE;
            return FALSE;
        }
```

```
        case QUANTITATIVE_CCM: {
            quantity *q1, *q2;
            q1 = spec_get_constant_quantity_if_any(spec1);
            q2 = spec_get_constant_quantity_if_any(spec2);
            if (q1 == q2) return TRUE;
            return FALSE;
        }
        case SPECIAL_CCM: {
            COMPARE_CONSTANTS(ACTION_NAME, action_name)
            COMPARE_CONSTANTS(ACTIVITY, activity)
            COMPARE_CONSTANTS(EQUATION, equation)
            COMPARE_CONSTANTS(PROPERTY, property_name)
            COMPARE_CONSTANTS(RELATION, binary_predicate)
            COMPARE_CONSTANTS(RULE, booked_rule)
            COMPARE_CONSTANTS(RULEBOOK, rulebook)
            COMPARE_CONSTANTS(RULEBOOK_OUTCOME, named_rulebook_outcome)
            COMPARE_CONSTANTS(SCENE, scene)
            COMPARE_CONSTANTS(TABLE, table)
            COMPARE_CONSTANTS(TABLE_COLUMN, table_column)
            COMPARE_CONSTANTS(UNDERSTANDING, grammar_verb)
            COMPARE_CONSTANTS(USEOPTION, use_option)
            if (is_kova(kov1, OBJECT_TY)) {
                world_object *wo1 = OBJECT_spec_to_world_object(spec1);
                world_object *wo2 = OBJECT_spec_to_world_object(spec2);
                if (wo1 == wo2) return TRUE;
                return FALSE;
            }
        }
    }
    return FALSE;
}
```

The function spec_compare_CONSTANT is called from 7/tc and 10/tab.

§16. Pretty-printing.

```
void write_VALUE_out_in_English(specification *spec, char *text) {
    switch (spec_get_species(spec)) {
        case PHRASE_TO_DECIDE_VALUE_SPC: {
            kind_of_value *dtr = spec_evaluates_to(spec);
            sprintf(text+strlen(text), "an instruction to work out ");
            copy_kov_to_string(dtr, text, FALSE);
            break;
        }
        case CONSTANT_SPC: {
            int w1 = spec->word_ref1, w2 = spec->word_ref2;
            if (spec_is_generic_CONSTANT(spec)) {
                copy_kov_to_string(spec_get_kind_of_value(spec), text, FALSE);
                return;
            }
            if (spec_is_CONSTANT_of_kova(spec, PROPERTY_TY)) {
                if (w1 > 0) print_modest_sized_text_to_string(w1, w2, text+strlen(text));
                else sprintf(text+strlen(text), "the name of a property");
                return;
```

```
            }
            print_modest_sized_text_to_string(w1, w2, text+strlen(text));
            break;
        }
    }
}
```

The function write_VALUE_out_in_English is called from 7/spec.

§**17.** And for the log:

```
void log_VALUE_spec_details(specification *spec) {
    switch (spec_get_species(spec)) {
        case CONSTANT_SPC: {
            quantity *q = spec_get_constant_quantity_if_any(spec);
            if (q)
                if (qty_get_I6_representation(q))
                    LOG("(%s)", qty_get_I6_representation(q));
            if (spec_is_actual_CONSTANT_of_kova(spec, OBJECT_TY)) {
                if (spec_test_flag(spec, SELF_OBJECT_SPFLAG)) LOG("(-self-)");
                else if (spec_test_flag(spec, NOTHING_OBJECT_SPFLAG)) LOG("(-nothing-)");
                else LOG("($O)", OBJECT_spec_to_world_object(spec));
            }
        }
    }
}
```

The function log_VALUE_spec_details is called from 7/spec.

§**18. Compilation.** First: clearly everything in this family evaluates, but what KOV does the result have?

```
kind_of_value *kov_when_VALUE_is_evaluated(specification *spec) {
    if (spec == NULL) internal_error("kov_when_VALUE_is_evaluated on NULL");
    switch (spec_get_species(spec)) {
        case CONSTANT_SPC:
            if (spec_is_actual_CONSTANT_of_kova(spec, OBJECT_TY))
                ⟨Work out the KOV for a constant object 19⟩;
            return spec_get_kind_of_value(spec);
        case PHRASE_TO_DECIDE_VALUE_SPC:
            ⟨Work out the KOV returned by a phrase 20⟩;
    }
    internal_error("unknown evaluating VALUE type"); return NULL;
}
```

The function kov_when_VALUE_is_evaluated is called from 5/aph, 6/simp, 7/spec, 7/stsp, 7/tc, 8/mass and 12/phtd.

§**19.** This is trickier than it looks. What KOV shall we say that the constants "nothing", "Cobbled Crawl", or "animal" have? The answer is the narrowest we can: "nothing" comes out as "object", "Cobbled Crawl" as "room" (a KOVKO), "animal" as itself (ditto).

⟨Work out the KOV for a constant object 19⟩ ≡

```
if (spec_test_flag(spec, SELF_OBJECT_SPFLAG)) return kova(OBJECT_TY);
else if (spec_test_flag(spec, NOTHING_OBJECT_SPFLAG)) return kova(OBJECT_TY);
else {
    world_object *wo_if_any = OBJECT_spec_to_world_object(spec);
    if (wo_if_any->kind_flag) return kovko(wo_if_any);
    if (wo_if_any->kind) return kovko(wo_if_any->kind);
}
```

This code is used in §18.

§**20.** This too is tricky. Some phrases to decide values are unambiguous. If they say they are "To decide a rule: ...", then clearly the return value will be a `kova(RULE_TY)`. But others are "polymorphic" – Greek for many-shaped, but in this context, it means that the return value's kind depends on the kinds of its arguments; addition is like this, for instance.

Compounding the problem is that we don't actually know which phrase will be invoked – we only have a list of possibilities. All of them return values, but those may have different kinds, and some may be polymorphic.

So what are we to do? First, we find the "deciding invocation": the first entry in the list which has been passed by the type-checker, or if none of them has, then the first entry of all. If the deciding invocation is of a phrase with an unambiguous KOV, then that's of course the answer. If it is polymorphic, then we look to see if typechecking has already resolved the difficulty by showing the result, and if so, then that's the answer. The worst case, then, is when we have a polymorphic phrase and typechecking hasn't yet sorted matters out – in that event we return simply "value" as the KOV, an extremely weak if certainly true answer.

We resort to returning `NULL`, an unknown KOV, only when the invocation list is empty. This should never happen except possibly after recovering from some problem message.

⟨Work out the KOV returned by a phrase 20⟩ ≡

```
invocation *deciding_inv = NULL, *first_inv = NULL;
INVOCATION_VARIABLE(inv);
LOOP_THROUGH_INVOCATION_LIST(inv, spec_invocation_list(spec)) {
    if (first_inv == NULL) first_inv = inv;
    if (inv_test_flag(inv, PASSED_INVFLAG)) { deciding_inv = inv; break; }
}
if (deciding_inv == NULL) deciding_inv = first_inv;
if (deciding_inv) {
    phrase *ph = deciding_inv->phrase_invoked;
    if (ph) {
        switch(phtd_determine_return_modifier(&(ph->type_data))) {
            case NO_RETURN_RTY: return NULL;
            case POLYMORPHIC_RTY:
                if (deciding_inv->kov_resulting) return deciding_inv->kov_resulting;
                return kova(ANY_VALUE_TY);
            case STANDARD_RTY:
                return phtd_get_return_kov(&(ph->type_data));
        }
    }
}
return NULL;
```

This code is used in §18.

§**21.** And so to the code for compiling constants.

```
void compile_VALUE_spec(OUTPUT_STREAM, specification *spec_found) {
    switch(spec_get_species(spec_found)) {
        case PHRASE_TO_DECIDE_VALUE_SPC:
            compile_invocational_phrase(OUT, spec_found);
            return;
        case CONSTANT_SPC: {
            kind_of_value *kov_of_constant = spec_get_kind_of_value(spec_found);
            ⟨Worry about the case of block values stored on the heap 22⟩;
            int ccm = kov_get_constant_compilation_method(kov_of_constant);
            switch(ccm) {
                case NONE_CCM:                                  constant values of this kind cannot exist
                    LOG("SP: $S; kov: $u\n", spec_found, kov_of_constant);
                    internal_error("Tried to compile CONSTANT SP for a disallowed data type");
                    return;
                case LITERAL_CCM: ⟨Compile a literal-compilation-mode constant 23⟩; return;
                case QUANTITATIVE_CCM: ⟨Compile a quantitative-compilation-mode constant 24⟩; return;
                case SPECIAL_CCM: ⟨Compile a special-compilation-mode constant 25⟩; return;
            }
        }
    }
}
```

The function compile_VALUE_spec is called from 7/cfsp.

§**22.** Suppose we're asked to compile an indexed text. What we normally do is to compile the name of an I6 `Constant` such as `Blk_Const_17`, whose value will be a pointer to data which will be placed on the heap. We call `store_block_value` to remember what the actual text was, because we're going to need to compile it in the end, even if we're deferring that now. And when that day dawns, we will have the compilation mode `BLOCK_CONSTANT_CMODE` set, to avoid going into an infinite regression.

This applied to all block-value KOVs except for the KOVCONSs – at present, just the "list of..." constructor. This makes its own arrangements; see below.

⟨Worry about the case of block values stored on the heap 22⟩ ≡

```
    if ((kov_uses_pointer_values(kov_of_constant)) && (is_kovcon(kov_of_constant) == FALSE)) {
        if (TEST_COMPILATION_MODE(BLOCK_CONSTANT_CMODE) == FALSE) {
            WRITE("Blk_Const_%d", store_block_value(spec_copy(spec_found)));
            return;
        }
    }
```

This code is used in §21.

§**23.** With that out of the way, there are three basic compilation modes.

Here, the literal-parser is used to resolve the text of the SP to an integer. I6 is typeless, of course, so it doesn't matter that this is not necessarily a `NUMBER_TY`: all that matters is that the correct integer value is compiled.

⟨Compile a literal-compilation-mode constant 23⟩ ≡

```
if (spec_found->word_ref1 < 0) {
    LOG("SP: $S; kov: $u\n", spec_found, kov_of_constant);
    internal_error("Text no longer available for CONSTANT compilation");
}
if (kov_compare(is_a_literal(spec_found->word_ref1, spec_found->word_ref2),
    kov_of_constant) == FALSE) {
    LOG("SP: $S; kov: $u\n", spec_found, kov_of_constant);
    internal_error("Type anomaly for CONSTANT compilation");
}
WRITE("%d", last_literal_evaluated);
```

This code is used in §21.

§**24.** Whereas here, a quantity is attached.

⟨Compile a quantitative-compilation-mode constant 24⟩ ≡

```
if (is_kova(kov_of_constant, SCENE_TY)) {
    scene *sc = SCENE_spec_to_scene(spec_found);
    WRITE("%d", sc->allocation_id + 1);
    return;
}
quantity *q = RETRIEVE_FROM_SPEC(spec_found, quantity);
compile_quantity_name_to_string(OUT, q);
```

This code is used in §21.

§**25.** Otherwise there are just miscellaneous different things to do in different kinds of value:

⟨Compile a special-compilation-mode constant 25⟩ ≡

```
if (is_kova(kov_of_constant, ACTION_NAME_TY)) {
    action_name *an = ACTION_NAME_spec_to_action_name(spec_found);
    WRITE("##%s", an_get_I6_representation(an));
    return;
}
if (is_kova(kov_of_constant, ACTIVITY_TY)) {
    activity *act = ACTIVITY_spec_to_activity(spec_found);
    WRITE("%s", av_get_I6_representation(act));
    return;
}
if (is_kova(kov_of_constant, DESCRIPTION_OF_ACTION_TY)) {
    action_pattern *ap = RETRIEVE_FROM_SPEC(spec_found, action_pattern);
    compile_action_pattern_match(OUT, *ap, FALSE);
    return;
}
if (is_kova(kov_of_constant, EQUATION_TY)) {
    equation *eqn = EQUATION_spec_to_equation(spec_found);
    WRITE("%s", eqn_get_I6_representation(eqn));
    return;
}
```

```
if (is_kova(kov_of_constant, EXTERNALFILE_TY)) {
    kind_of_value *ial = is_a_literal(spec_found->word_ref1, spec_found->word_ref2);
    if (is_kova(ial, EXTERNALFILE_TY)) compile_exf_constant(OUT, last_literal_evaluated);
    return;
}
if ((is_kova(kov_of_constant, OBJECT_DESCRIPTION_TY)) ||
    (is_kova(kov_of_constant, VALUE_DESCRIPTION_TY))) {
    compile_multiple_use_proposition(OUT, spec_found);
    return;
}
if (is_kova(kov_of_constant, LIST_OF_TY)) {
    compile_literal_list(OUT, spec_found->word_ref1);
    return;
}
if (is_kova(kov_of_constant, OBJECT_TY)) {
    if (spec_test_flag(spec_found, SELF_OBJECT_SPFLAG)) WRITE("self");
    else if (spec_test_flag(spec_found, NOTHING_OBJECT_SPFLAG)) WRITE("nothing");
    else {
        world_object *wo = OBJECT_spec_to_world_object(spec_found);
        WRITE("%s", wo_get_I6_representation(wo));
    }
    return;
}
if (is_kova(kov_of_constant, PROPERTY_TY)) {
    ⟨Compile property constants 26⟩;
    return;
}
if (is_kova(kov_of_constant, QUOT_TY)) {
    if (spec_found->word_ref1 < 0)
        internal_error("Text no longer available for CONSTANT/QUOT");
    compile_quotation(OUT, spec_found->word_ref1);
    return;
}
if (is_kova(kov_of_constant, RELATION_TY)) {
    binary_predicate *bp = RELATION_spec_to_binary_predicate(spec_found);
    WRITE("%d", bp->allocation_id);
    return;
}
if (is_kova(kov_of_constant, RULE_TY)) {
    booked_rule *br = RULE_spec_to_booked_rule(spec_found);
    br_compile(OUT, br);
    return;
}
if (is_kova(kov_of_constant, RULEBOOK_TY)) {
    rulebook *rb = RULEBOOK_spec_to_rulebook(spec_found);
    WRITE("%d", rb->allocation_id);
    return;
}
if (is_kova(kov_of_constant, RULEBOOK_OUTCOME_TY)) {
    named_rulebook_outcome *rbno =
        RULEBOOK_OUTCOME_spec_to_named_rulebook_outcome(spec_found);
    WRITE("RBNO_%d", rbno->allocation_id);
    return;
```

```
    }
    if (is_kova(kov_of_constant, STORED_ACTION_TY)) {
        action_pattern *ap = RETRIEVE_FROM_SPEC(spec_found, action_pattern);
        compile_action_pattern_to_block(OUT, ap);
        return;
    }
    if (is_kova(kov_of_constant, TABLE_TY)) {
        table *t = TABLE_spec_to_table(spec_found);
        WRITE("%s", tab_get_I6_representation(t));
        return;
    }
    if (is_kova(kov_of_constant, TABLE_COLUMN_TY)) {
        table_column *tc = TABLE_COLUMN_spec_to_table_column(spec_found);
        WRITE("%d", tc_get_column_id(tc));
        return;
    }
    if (is_kova(kov_of_constant, TEXT_TY)) {
        if (spec_found->word_ref1 < 0)
            internal_error("Text no longer available for CONSTANT/TEXT");
        compile_literal_text(OUT, spec_found->word_ref1);
        return;
    }
    if (is_kova(kov_of_constant, TEXT_ROUTINE_TY)) {
        ph_stack_frame *phsf = NULL;
        if (spec_found->word_ref1 < 0)
            internal_error("Text no longer available for CONSTANT/TEXT_ROUTINE");
        if (TEST_COMPILATION_MODE(PERMIT_LOCALS_IN_TEXT_CMODE)) {
            WRITE("(");
            phsf = phsf_compile_local_storage(OUT, current_stack_frame());
        }
        WRITE("text_routine_%d", text_routine_cue(spec_found->word_ref1, phsf));
        if (TEST_COMPILATION_MODE(PERMIT_LOCALS_IN_TEXT_CMODE))
            WRITE(")");
        return;
    }
    if (is_kova(kov_of_constant, UNDERSTANDING_TY)) {
        if (spec_found->word_ref1 < 0)
            internal_error("Text no longer available for CONSTANT/UNDERSTANDING");
        compile_understanding(OUT,
            spec_found->word_ref1, spec_found->word_ref2, FALSE);
        return;
    }
    if (is_kova(kov_of_constant, USEOPTION_TY)) {
        use_option *uo = USEOPTION_spec_to_use_option(spec_found);
        WRITE("%d", uo->allocation_id);
        return;
    }
    LOG("Kov is $u\n", kov_of_constant);
    internal_error("no special ccm provided");
```

This code is used in §21.

§**26.** The interesting, read "unfortunate", case is that of constant property names. The curiosity here is that it's legal to store the nameless negation of an either/or property in a `PROPERTY_TY` constant. This is purely so that the following ungainly syntax works:

```
change X to not P;
```

Recall that in Inform 6 syntax, an attribute `attr` can be negated in sense in several contexts by using a tilde: `~attr`.

⟨Compile property constants 26⟩ ≡

```
int parity = 1;
if [[(spec_found) == not ***]] parity = -1;

property_name *prn = PROPERTY_spec_to_property_name(spec_found);
if (prn == NULL) internal_error("PROPERTY SP with null property");

if (prn_is_either_or(prn)) {
    if (prn_either_or_implemented_as_attribute(prn)) {
        if (prn_either_or_stored_in_negation(prn))
            WRITE("%s%s", (parity>0)?"~":"",
                prn_get_i6_identifier(prn_either_or_get_negation(prn)));
        else
            WRITE("%s%s", (parity<0)?"~":"",
                prn_get_i6_identifier(prn));
    } else {
        if (prn_either_or_stored_in_negation(prn))
            WRITE("%s",
                prn_get_i6_identifier(prn_either_or_get_negation(prn)));
        else WRITE("%s", prn_get_i6_identifier(prn));
    }
} else WRITE("%s", prn_get_i6_identifier(prn));
```

This code is used in §25.

§**27.** See above for the discussion of block-value constants. At present we always allocate 32 bytes for the initial block, whatever the KOV.

```
int store_block_value(specification *spec) {
    stored_block_value *sbv = CREATE(stored_block_value);
    sbv->stored_constant = spec;
    sbv->size_of_block = 32;
    return sbv->allocation_id;
}
```

§**28.** And this is where all of those block constants are redeemed. This is probably the winner of the all-Inform shouting function competition: all those macros, all those capitals.

```
void create_block_constants(OUTPUT_STREAM) {
    stored_block_value *sbv;
    LOOP_OVER (sbv, stored_block_value) {
        WRITE("Array Blk_Const_%d --> %d;\n",
            sbv->allocation_id, sbv->size_of_block);
    }
    WRITE("[ CreateBlockConstants;\n"); INDENT;
    BEGIN_COMPILATION_MODE;
    COMPILATION_MODE_ENTER(BLOCK_CONSTANT_CMODE);
    LOOP_OVER (sbv, stored_block_value) {
        WRITE("BlkValueInitialCopy(Blk_Const_%d, ", sbv->allocation_id);
        compile_VALUE_spec(OUT, sbv->stored_constant);
        WRITE(");\n");
    }
    END_COMPILATION_MODE;
    OUTDENT; WRITE("];\n");
}
```

The function create_block_constants is invoked by a command in a `.i6t` template file.

STORAGE Specifications 7/stsp

Purpose

Documentation on and functions handling specifications which fall into the STORAGE family.

§**1. Creation.** "Storage items" are what other programming languages might call "lvalues", since they can occur on the left of an assignment sign: they are values which can be written to. Values which can only be read ("rvalues") form the `VALUE` family. There are currently five `STORAGE` species:

`LOCAL_VARIABLE_SPC` refers to a specific local variable, so it has meaning only within the routine currently being compiled. In the compiled code, it will actually be an I6 local variable; in I7 terms it is a "let" variable. The data field of the SP holds the local variable number in the current routine. (These number upwards from 0, and are compiled to I6 local variables named in the form `t_0`, `t_1`, ...) There are no references or arguments.

`NONLOCAL_VARIABLE_SPC` refers to a variable of any other scope: that is, a global variable, or perhaps a rulebook, action or activity variable. The important distinction between these other scopes and local scope is essentially that local variables live on the I6 call-stack and have only a local namespace, whereas others correspond to array entries or global I6 variables and share a global namespace. (It is basically a matter of implementation convenience which makes us divide the stock of variables into two different species this way.) A `quantity *` pointer is attached, identifying the name of the variable in question. There are no arguments.

`PROPERTY_VALUE_SPC` represents a given (value-)property of a given object, *not* the name of a property in abstract. Thus "description of the Police Commissioner" qualifies, but "description" does not. There are two arguments: the property and the object which possesses it, respectively.

`TABLE_ENTRY_SPC` represents a given entry to a table, which can be referred to in several different ways. There are four different kinds of table reference, distinguished by the number of arguments found:

(1) 1 argument. By column name only, the table and row to be understood from context because we have selected a row in the surrounding source text.
(2) 2 arguments. Used as a condition to see if a value is listed in a given column of a given table. Argument 0 must be a constant of KOV `TABLE_COLUMN_TY`, argument 1 any value of KOV `TABLE_TY`. (Argument 0 has to be a constant because it is not type-safe to allow looping through columns, say: different columns have different KOVs, and the compiler would be unable to tell the KOV of the result of such a lookup. The same doesn't apply to argument 1, perhaps oddly, because Inform requires that every column name have the same KOV in every table using it. So the choice of table does not have to be a constant, and this allows for some interesting data structures to be built.)
(3) 3 arguments. An explicitly specified entry. The arguments are the table column, row number, and table respectively.
(4) 4 arguments. A reference to the X corresponding to a Y value of Z in table T. The arguments are X, Y, Z, T respectively.

`LIST_ENTRY_SPC` represents a given entry in a list, which is much simpler: there are two arguments, the list and the numerical index, which counts from 1.

Note that property names, table names, and lists themselves are not storage items as such – they are places where storage items are found. They are all in the `VALUE` family.

```
void create_STORAGE_species(void) {
    type_ID_set_description(STORAGE_FMY, "a stored value");
    type_ID_set_source_name(STORAGE_FMY, "STORAGE_FMY");
    type_ID_set_flag(STORAGE_FMY, EVALUATING_SPCFLAG);
    type_ID_permit_pair(STORAGE_FMY, LOCAL_VARIABLE_SPC,
        TYPE_PARSED_SPCONTEXT + PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
```

```
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(LOCAL_VARIABLE_SPC, "a temporary 'let' or 'repeat' variable");
    type_ID_set_parsing_names(LOCAL_VARIABLE_SPC, variable_V, variables_V);
    type_ID_set_source_name(LOCAL_VARIABLE_SPC, "LOCAL_VARIABLE_SPC");
    type_ID_set_flag(LOCAL_VARIABLE_SPC, ASSOCIATED_KOV_SPCFLAG);
    type_ID_permit_pair(STORAGE_FMY, NONLOCAL_VARIABLE_SPC,
        TYPE_PARSED_SPCONTEXT + PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(NONLOCAL_VARIABLE_SPC, "the name of a variable");
    type_ID_set_source_name(NONLOCAL_VARIABLE_SPC, "NONLOCAL_VARIABLE_SPC");
    type_ID_set_flag(NONLOCAL_VARIABLE_SPC, ASSOCIATED_KOV_SPCFLAG);
    type_ID_permit_pair(STORAGE_FMY, PROPERTY_VALUE_SPC,
        PARSED_SPCONTEXT + TYPE_PARSED_SPCONTEXT + TYPE_EXPECTED_SPCONTEXT +
        TYPE_FOUND_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(PROPERTY_VALUE_SPC, "a property whose value is ");
    type_ID_set_source_name(PROPERTY_VALUE_SPC, "PROPERTY_VALUE_SPC");
    type_ID_set_parsing_names(PROPERTY_VALUE_SPC, property_value_V, property_values_V);
    type_ID_set_flag(PROPERTY_VALUE_SPC, ARGUMENTS_SPCFLAG);
    type_ID_permit_pair(STORAGE_FMY, TABLE_ENTRY_SPC,
        TYPE_PARSED_SPCONTEXT + PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(TABLE_ENTRY_SPC, "an entry in a table");
    type_ID_set_parsing_names(TABLE_ENTRY_SPC, table_reference_V, table_references_V);
    type_ID_set_source_name(TABLE_ENTRY_SPC, "TABLE_ENTRY_SPC");
    type_ID_set_flag(TABLE_ENTRY_SPC, ARGUMENTS_SPCFLAG);
    type_ID_permit_pair(STORAGE_FMY, LIST_ENTRY_SPC,
        TYPE_PARSED_SPCONTEXT + PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(LIST_ENTRY_SPC, "an entry in a list");
    type_ID_set_parsing_names(LIST_ENTRY_SPC, list_entry_V, list_entries_V);
    type_ID_set_source_name(LIST_ENTRY_SPC, "LIST_ENTRY_SPC");
    type_ID_set_flag(LIST_ENTRY_SPC, ARGUMENTS_SPCFLAG);
}
```

The function create_STORAGE_species is called from 7/tids.

§**2.** And here are some convenient creators. Variables:

```
specification *new_LOCAL_VARIABLE_spec(int w1, int w2, int ix) {
    specification *spec = spec_new(STORAGE_FMY, LOCAL_VARIABLE_SPC);
    spec->word_ref1 = w1; spec->word_ref2 = w2;
    spec_set_data(spec, LOCAL_NUMBER_SPDATA, ix);
    return spec;
}
specification *new_generic_LOCAL_VARIABLE_type(kind_of_value *kov) {
    specification *spec = spec_new(STORAGE_FMY, LOCAL_VARIABLE_SPC);
    spec_make_generic(spec);
    spec_set_kind_of_value(spec, kov);
    return spec;
}
specification *new_actual_NONLOCAL_VARIABLE_type(quantity *q) {
    specification *spec = spec_new(STORAGE_FMY, NONLOCAL_VARIABLE_SPC);
```

```
    ATTACH_TO_SPEC(spec, quantity, q);
    spec->word_ref1 = q->word_ref1;
    spec->word_ref2 = q->word_ref2;
    return spec;
}
specification *new_generic_NONLOCAL_VARIABLE_type(kind_of_value *kov) {
    specification *spec = spec_new(STORAGE_FMY, NONLOCAL_VARIABLE_SPC);
    spec_make_generic(spec);
    spec_set_kind_of_value(spec, kov);
    return spec;
}
```

The function new_LOCAL_VARIABLE_spec is called from 5/aph, 5/tandv and 12/cinv.
The function new_generic_LOCAL_VARIABLE_type is called from 5/mlc.
The function new_actual_NONLOCAL_VARIABLE_type is called from 6/asp, 7/specv, 8/creat and 8/knowp.
The function new_generic_NONLOCAL_VARIABLE_type is called from 5/mlc.

§**3.** Table entries have their arguments filled in by the relevant routines in "Meaning List Conversion":

```
specification *new_TABLE_ENTRY_spec(void) {
    specification *spec = spec_new(STORAGE_FMY, TABLE_ENTRY_SPC);
    return spec;
}
```

The function new_TABLE_ENTRY_spec is called from 5/mlc.

§**4.** List entries:

```
specification *new_LIST_ENTRY_spec(specification *owner, specification *index) {
    specification *spec = spec_new(STORAGE_FMY, LIST_ENTRY_SPC);
    spec_set_argument(spec, 0, owner);
    spec_set_argument(spec, 1, index);
    return spec;
}
```

The function new_LIST_ENTRY_spec is called from 5/mlc.

§**5.** Property values are constructed out of what's often only implied text: for instance, "description" sometimes means "the description [of the `self` object]". We give them a word range which is minimal such that it must contain word ranges of both property and owner, if given. Thus "carrying capacity of the trunk" will result from "carrying capacity" and "trunk". This is not very scientific, perhaps, but it's done only to make problem messages more readable.

```
specification *new_PROPERTY_VALUE_spec(specification *prop, specification *owner) {
    specification *spec = spec_new(STORAGE_FMY, PROPERTY_VALUE_SPC);
    spec_set_argument(spec, 0, prop);
    spec_set_argument(spec, 1, owner);
    if ((prop->word_ref1 >= 0) && (owner->word_ref1 >= 0)) {
        spec->word_ref1 = prop->word_ref1;
        if (spec->word_ref1 > owner->word_ref1) spec->word_ref1 = owner->word_ref1;
        spec->word_ref2 = prop->word_ref2;
        if (spec->word_ref2 < owner->word_ref2) spec->word_ref2 = owner->word_ref2;
    }
    return spec;
}
```

The function new_PROPERTY_VALUE_spec is called from 5/mlc, 6/simp and 7/tc.

§6. Testing.

```
int spec_get_storage_form(specification *spec) {
    if (family_is(spec, STORAGE_FMY)) return spec_get_species(spec);
    return UNKNOWN;
}
```

The function spec_get_storage_form is called from 5/mlc, 6/simp, 6/equal, 6/defer, 6/cind, 7/tc, 8/mass, 9/qty, 11/ap, 12/phtd, 12/cinv and 12/ambig.

§7. More specifically:

```
int spec_is_actual_NONLOCAL_VARIABLE(specification *spec) {
    if ((species_is(spec, NONLOCAL_VARIABLE_SPC)) && (spec_is_actual(spec))) return TRUE;
    return FALSE;
}
int spec_is_generic_NONLOCAL_VARIABLE(specification *spec) {
    if ((species_is(spec, NONLOCAL_VARIABLE_SPC)) && (spec_is_generic(spec))) return TRUE;
    return FALSE;
}
```

The function spec_is_actual_NONLOCAL_VARIABLE is called from 6/equal and 8/mass.
The function spec_is_generic_NONLOCAL_VARIABLE is called from 8/creat, 8/mass and 9/pp.

§8. And more specifically still:

```
int spec_is_this_NONLOCAL_VARIABLE(specification *spec, quantity *q) {
    if ((spec_is_actual_NONLOCAL_VARIABLE(spec)) &&
        (q == (RETRIEVE_FROM_SPEC(spec, quantity)))) return TRUE;
    return FALSE;
}
```

The function spec_is_this_NONLOCAL_VARIABLE is called from 6/equal.

§9. Not all non-local variables are global – some have scope local to rulebooks, actions and the like:

```
int spec_is_global_variable(specification *spec) {
    if (spec_is_actual_NONLOCAL_VARIABLE(spec)) {
        quantity *q = RETRIEVE_FROM_SPEC(spec, quantity);
        if ((q) && (qty_is_a_global_variable(q))) return TRUE;
    }
    return FALSE;
}
```

The function spec_is_global_variable is called from 6/cind and 10/eqns.

§10. Pretty-printing.

```
void write_STORAGE_out_in_English(specification *spec, char *text) {
    switch(spec_get_species(spec)) {
        case LOCAL_VARIABLE_SPC:
            strcpy(text+strlen(text), "a temporary 'let' or 'repeat' variable");
            break;
        case NONLOCAL_VARIABLE_SPC:
            if (spec_get_kind_of_value(spec)) {
                copy_kov_to_string(spec_get_kind_of_value(spec), text, FALSE);
                strcpy(text+strlen(text), " that varies");
            } else strcpy(text+strlen(text), "a non-temporary variable");
            break;
        case TABLE_ENTRY_SPC:
            sprintf(text+strlen(text), "a table entry");
            break;
        case LIST_ENTRY_SPC:
            sprintf(text+strlen(text), "a list entry");
            break;
        case PROPERTY_VALUE_SPC:
            if ((spec_get_argc(spec) == 2) &&
                (spec_is_CONSTANT_of_kova(spec_get_argument(spec, 0), PROPERTY_TY))) {
                property_name *prn = spec_get_property_name_if_any(spec_get_argument(spec, 0));
                specification *pval = new_generic_CONSTANT_type(prn_get_kind_of_value(prn));
                sprintf(text+strlen(text), "a property whose value is ");
                write_specification_out_in_English(pval, text+strlen(text));
            } else sprintf(text+strlen(text), "a property belonging to something");
            break;
    }
}
```

The function write_STORAGE_out_in_English is called from 7/spec.

§11. And the log.

```
void log_STORAGE_spec_details(specification *spec) {
    switch (spec_get_species(spec)) {
        case LOCAL_VARIABLE_SPC:
            if (spec_get_data(spec, LOCAL_NUMBER_SPDATA) == -1) LOG("(existing)");
            else LOG("(t_%d;$u)",
                spec_get_data(spec, LOCAL_NUMBER_SPDATA),
                unproblematic_data_type_of_local(
                    spec_get_data(spec, LOCAL_NUMBER_SPDATA)));
            break;
        case NONLOCAL_VARIABLE_SPC:
            if (spec_is_actual(spec)) {
                quantity *q = RETRIEVE_FROM_SPEC(spec, quantity);
                if (qty_get_I6_representation(q))
                    LOG("(%s)", qty_get_I6_representation(q));
            }
            break;
    }
}
```

The function log_STORAGE_spec_details is called from 7/spec.

§12. Compilation.

```
kind_of_value *kov_when_STORAGE_is_evaluated(specification *spec) {
    if (spec == NULL) internal_error("kov_when_VALUE_is_evaluated on NULL");
    switch (spec_get_species(spec)) {
        case LOCAL_VARIABLE_SPC: ⟨Return the KOV of a local variable 13⟩;
        case NONLOCAL_VARIABLE_SPC: ⟨Return the KOV of a non-local variable 14⟩;
        case TABLE_ENTRY_SPC: ⟨Return the KOV of a table entry 15⟩;
        case LIST_ENTRY_SPC: ⟨Return the KOV of a list entry 16⟩;
        case PROPERTY_VALUE_SPC: ⟨Return the KOV of a property value 17⟩;
    }
    internal_error("unknown evaluating STORAGE species"); return NULL;
}
```

The function kov_when_STORAGE_is_evaluated is called from 7/spec.

§13.

⟨Return the KOV of a local variable 13⟩ ≡

```
    int k = spec_get_data(spec, LOCAL_NUMBER_SPDATA);
    if (k == -1) return kova(ANY_VALUE_TY);                    for "existing"
    return unproblematic_data_type_of_local(k);
```

This code is used in §12.

§14.

⟨Return the KOV of a non-local variable 14⟩ ≡

```
    if (spec_is_generic(spec)) return kova(ANY_VALUE_TY);
    quantity *q = RETRIEVE_FROM_SPEC(spec, quantity);
    return qty_kind_of_value(q);
```

This code is used in §12.

§15. In every form of table entry, argument 0 is the column, and the column is enough to determine the KOV:

⟨Return the KOV of a table entry 15⟩ ≡

```
    if (spec_get_argc(spec) > 0) {                  i.e., always, for actual table entry specifications
        specification *fts = spec_get_argument(spec, 0);
        table_column *tc = TABLE_COLUMN_spec_to_table_column(fts);
        return get_data_type_stored(tc);
    }
    return NULL;                                    can happen when scanning phrase arguments, which are generic
```

This code is used in §12.

§16.

⟨Return the KOV of a list entry 16⟩ ≡
```
if (spec_get_argc(spec) == 2) {                    i.e., always, for actual list entry specifications
    kind_of_value *kov1 = spec_evaluates_to(spec_get_argument(spec, 0));
    if (kovcon_get_base(kov1)) return kovcon_get_base(kov1);
    return kova(ANY_VALUE_TY);                     to help the type-checker produce better problem messages
}
return NULL;                                       can happen when scanning phrase arguments, which are generic
```

This code is used in §12.

§17.

⟨Return the KOV of a property value 17⟩ ≡
```
if (spec_get_argc(spec) == 2) {
    property_name *prn = spec_get_property_name_if_any(spec_get_argument(spec, 0));
    if ((prn) && (prn_is_either_or(prn) == FALSE)) return prn_get_kind_of_value(prn);
    return kova(ANY_VALUE_TY);                     to help the type-checker produce better problem messages
}
return NULL;                                       can happen when scanning phrase arguments, which are generic
```

This code is used in §12.

§18. **Rvalue compilation.** We finally reach the compilation routine which produces an I6 expression evaluating to the contents of the storage item specified.

```
void compile_STORAGE_spec(OUTPUT_STREAM, specification *spec_found) {
    switch (spec_get_species(spec_found)) {
        case LOCAL_VARIABLE_SPC: ⟨Compile a local variable specification 19⟩;
        case NONLOCAL_VARIABLE_SPC: ⟨Compile a non-local variable specification 20⟩;
        case PROPERTY_VALUE_SPC: ⟨Compile a property value specification 21⟩;
        case LIST_ENTRY_SPC: ⟨Compile a list entry specification 26⟩;
        case TABLE_ENTRY_SPC: ⟨Compile a table entry specification 27⟩;
        default: internal_error("unable to compile this STORAGE species");
    }
}
```

The function compile_STORAGE_spec is called from 7/cfsp.

§19.

⟨Compile a local variable specification 19⟩ ≡
```
if (spec_get_data(spec_found, LOCAL_NUMBER_SPDATA) == -1)
    internal_error("Compiled never-specified LOCAL VARIABLE SP");
WRITE("t_%d", spec_get_data(spec_found, LOCAL_NUMBER_SPDATA));
return;
```

This code is used in §18.

§**20.**

⟨Compile a non-local variable specification 20⟩ ≡

```
quantity *q = RETRIEVE_FROM_SPEC(spec_found, quantity);
compile_quantity_name_to_string(OUT, q);
return;
```

This code is used in §18.

§**21.**

⟨Compile a property value specification 21⟩ ≡

```
if (spec_get_argc(spec_found) != 2) internal_error("malformed PROPERTY_OF SP");
if (spec_get_argument(spec_found, 0) == NULL) internal_error("PROPERTY_OF with null arg 0");
if (spec_get_argument(spec_found, 1) == NULL) internal_error("PROPERTY_OF with null arg 1");
property_name *prn = spec_get_property_name_if_any(spec_get_argument(spec_found, 0));
if (prn == NULL) internal_error("PROPERTY_OF with null property");
specification *prop_spec = spec_get_argument(spec_found, 0);
specification *owner = spec_get_argument(spec_found, 1);
kind_of_value *owner_kov = spec_evaluates_to(owner);
⟨Reinterpret the "self" for what are unambiguously conditions of single things 22⟩;
if (is_kova(owner_kov, OBJECT_TY)) ⟨Compile a property value of an object 23⟩
else ⟨Compile a property value of another value 24⟩;
return;
```

This code is used in §18.

§**22.** When Inform reads a text with a substitution like so:

> if the signpost is visible, say "The signpost is still [signpost condition]."

...it has to decide which object is meant as the owner of the property "signpost condition". Ordinarily, missing property owners are the self object, which works nicely because `self` always has the right value at run-time when we're, e.g., printing names of things. But what if, as here, there is no formal indication of the owner? If we compile with the self object as owner, the code may fail at run-time, complaining about using a property of nothing.

The author who wrote the source text above, though, felt able to write "[signpost condition]" without any indication of its owner because there could only be one possible owner: the signpost. And so that's the convention we use here. We replace "self" as a default owner by the only possible owner.

⟨Reinterpret the "self" for what are unambiguously conditions of single things 22⟩ ≡

```
if (spec_is_self_object_constant(owner)) {
    world_object *wo = prn_condition_of_which_object(prn);
    if ((wo) && (wo->kind_flag == FALSE))
        owner = world_object_to_OBJECT_spec(wo);
}
```

This code is used in §21.

§**23.** For details of the routines called here, see "RTP.i6t" in the template.

⟨Compile a property value of an object 23⟩ ≡
```
WRITE("ValueProperty(");
⟨Compile the property's owner 25⟩;
WRITE(",");
spec_compile(OUT, prop_spec);
WRITE(")");
```
This code is used in §21.

§**24.**

⟨Compile a property value of another value 24⟩ ≡
```
int range = pp_get_prn_offset_in_kov(NULL, owner_kov);
int offset = pp_get_prn_offset_in_kov(prn, owner_kov);
if (offset < range) {
    WRITE("PropertyKOV(KOVP_%d, %d, ", kov_I6_ID(owner_kov), offset);
    ⟨Compile the property's owner 25⟩;
    WRITE(")");
}  else {
    WRITE("ValueProperty(");
    ⟨Compile the property's owner 25⟩;
    WRITE(",");
    spec_compile(OUT, prop_spec);
    WRITE(")");
}
```
This code is used in §21.

§**25.** During type-checking, a small number of `PROPERTY_VALUE_SPC` SPs are marked with the `RECORD_AS_SELF_SPFLAG` flag. Such a SP compiles not only to code performing the property lookup, but also setting the `self` I6 variable at run-time to the object whose property is being looked up. The point of this is to change the context used for implicit property lookups involved in the actual property: e.g., if the value of this property turns out to be text which contains a substitution referring vaguely to another property, then we need to make sure that this other property is looked up from the same object as produced the original text containing the substitution.

⟨Compile the property's owner 25⟩ ≡
```
if (spec_test_flag(spec_found, RECORD_AS_SELF_SPFLAG)) WRITE("self=");
spec_compile(OUT, owner);
```
This code is used in §23,24,23,24,23,24.

§**26.** List entries are blessedly simpler.

⟨Compile a list entry specification 26⟩ ≡
```
if (spec_get_argc(spec_found) != 2) internal_error("malformed LIST_OF SP");
if (spec_get_argument(spec_found, 0) == NULL) internal_error("LIST_OF with null arg 0");
if (spec_get_argument(spec_found, 1) == NULL) internal_error("LIST_OF with null arg 1");
WRITE("LIST_OF_TY_GetItem(");
spec_compile(OUT, spec_get_argument(spec_found, 0));
WRITE(",");
spec_compile(OUT, spec_get_argument(spec_found, 1));
WRITE(")");
return;
```

This code is used in §18.

§**27.** Table entries are simple too, but come in four variant forms:

⟨Compile a table entry specification 27⟩ ≡
```
switch(spec_get_argc(spec_found)) {
    case 1:
        we_need_ct_locals();
        WRITE("TableLookUpEntry(ct_0,");
        spec_compile(OUT, spec_get_argument(spec_found, 0));
        WRITE(",ct_1)");
        break;
    case 2:                                          never here except when printing debugging code
        WRITE("(false)");
        break;
    case 3:
        WRITE("TableLookUpEntry(");
        spec_compile(OUT, spec_get_argument(spec_found, 2));
        WRITE(",");
        spec_compile(OUT, spec_get_argument(spec_found, 0));
        WRITE(",");
        spec_compile(OUT, spec_get_argument(spec_found, 1));
        WRITE(")");
        break;
    case 4:
        WRITE("TableLookUpCorr(");
        spec_compile(OUT, spec_get_argument(spec_found, 3));
        WRITE(",");
        spec_compile(OUT, spec_get_argument(spec_found, 0));
        WRITE(",");
        spec_compile(OUT, spec_get_argument(spec_found, 1));
        WRITE(",");
        spec_compile(OUT, spec_get_argument(spec_found, 2));
        WRITE(")");
        break;
    default: internal_error("TABLE REFERENCE with bad number of args");
}
return;
```

This code is used in §18.

§**28. Lvalue compilation.** To recap, if an assignment takes the form "now X is Y" then X is the lvalue, Y is the rvalue. We only need to read Y, but we need to write X. `spec_compile` applied to a STORAGE item produces code suitable for reading it, i.e., suitable for use in position Y – but not in general suitable for X.

To compile the lvalue form of a storage item, we use the following schemas. These in effect take the rvalue form and modify it. There are three versions, according to the nature of the data being moved. In these schemas, `*1` expands to the storage item's rvalue form, and `*2` to the value being assigned to it.

```
define STORE_WORD_TO_WORD 1
define STORE_WORD_TO_POINTER 2
define STORE_POINTER_TO_POINTER 3

char *storage_class_schema(int storage_class, int kind_of_store) {
    switch(kind_of_store) {
        case STORE_WORD_TO_WORD:
            switch(storage_class) {
                case LOCAL_VARIABLE_SPC: return "*=-*1 = *2";
                case NONLOCAL_VARIABLE_SPC: return "*=-*1 = *2";
                case TABLE_ENTRY_SPC: return "*=-*1*-,1,*2)";
                case PROPERTY_VALUE_SPC: return "*=-Write*1*-,*2)";
                case LIST_ENTRY_SPC: return "*=-Write*1*-,*2)";
            }
            return "";
        case STORE_WORD_TO_POINTER:
            switch(storage_class) {
                case LOCAL_VARIABLE_SPC: return "*=-BlkValueCast(*1, *#1, *#2, *!2)";
                case NONLOCAL_VARIABLE_SPC: return "*=-BlkValueCast(*1, *#1, *#2, *!2)";
                case TABLE_ENTRY_SPC: return "*=-BlkValueCast(*1*-,5), *#1, *#2, *!2)";
                case PROPERTY_VALUE_SPC: return "*=-BlkValueCast(*1, *#1, *#2, *!2)";
                case LIST_ENTRY_SPC: return "*=-BlkValueCast(*1, *#1, *#2, *!2)";
            }
            return "";
        case STORE_POINTER_TO_POINTER:
            switch(storage_class) {
                case LOCAL_VARIABLE_SPC: return "*=-BlkValueCopy(*1, *2)";
                case NONLOCAL_VARIABLE_SPC: return "*=-BlkValueCopy(*1, *2)";
                case TABLE_ENTRY_SPC: return "*=-BlkValueCopy(*1*-,5), *2)";
                case PROPERTY_VALUE_SPC: return "*=-BlkValueCopy(*1, *2)";
                case LIST_ENTRY_SPC: return "*=-BlkValueCopy(*1, *2)";
            }
            return "";
    }
    return "";
}
```

The function storage_class_schema is called from 7/data.

CONDITION Specifications 7/cosp

Purpose

Documentation on and functions handling specifications which fall into the CONDITION family.

Definitions

¶1. One species of condition, `DESCRIPTION_SPC`, is complex enough to need its own packet of additional data, the "docket":

```
typedef struct description_docket {
    struct quantifier *quant;                                  such as "at most..." or "all"
    int quant_parameter;                                       such as 3 in "at most 3"
    int no_adjectives_applied;
    struct adjective_list_entry *adjectives_applied;           see below
    struct kind_of_value *specific_kov;                        everything of this KOV...
    struct world_object *specific_kind;                        ...or everything of this kind...
    struct world_object *specific_object;                      ...or just this specific object
    int calling_w1, calling_w2;                                "black box" if "...(called the black box)"
} description_docket;
```

The structure description_docket is private to this section.

¶2. An adjective list is a linked list of entry structures used with `DESCRIPTION_SPC` types, as follows:

```
typedef struct adjective_list_entry {
    adjectival_phrase *ref_to;
    int ref_positive;                                          one of the above forms
    struct adjective_list_entry *next;                         in the list in this docket
} adjective_list_entry;
```

The structure adjective_list_entry is private to this section.

---

§**1. Creation.** In Inform, conditions are not values, nor can values be used directly as conditions: we therefore need to provide the logical operations of AND, OR, and NOT structurally via the SP rather than implementing them as phrases like the arithmetic operators. (Conditions and values are kept separate even though it does complicate the type system because this provides cleaner resolution of ambiguities, and I don't repent of this, because the mixture of the two is sometimes unclear enough even in C: in natural language, it tends to look very odd indeed.)

So `LOGICAL_AND_SPC` and `LOGICAL_OR_SPC` imitate the effect of logical operators. They have two arguments which must themselves be CONDITIONs.

For a set of logical operators which is adequate in the Boolean algebra sense we also need negation, of course, but no `LOGICAL_NOT_SPC` type exists because instead we can simply mark a `CONDITION_FMY` type as negated by setting its `CONDITION_NEGATED_SPFLAG` flag. As a double-negative is a positive, a flag is all that is required.

§**2.** TEST_PROPOSITION_SPC and NOW_PROPOSITION_SPC each contain a predicate calculus sentence in the proposition fields of their SPs: there are no arguments.

When parsed, any such SP is always of TEST_PROPOSITION_SPC. It can only convert to the other form by successfully passing type-checking against a generic NOW_PROPOSITION_SPC token, such as the one which is the type of the argument of the phrase:

To now (P - now-condition): ...

Such checking can easily fail, because there are many conditions which can be tested but not asserted. (For instance, conditions in the past tense – you can ask whether it rained yesterday, but you can't demand that henceforth it didn't rain yesterday.)

§**3.** TEST_PHRASE_OPTION_SPC tests the use of a phrase option, and is the actual SP parsed for the second usage of the word "thoroughly" in the following example:

To prognosticate, swiftly or thoroughly: ...; if thoroughly, ...

It uses the SP's data field to refer to the option in question: its value is the bitmap value of the option, which will usually be 2^n where the option is the n-th in the list for this phrase, counting upwards from 0.

§**4.** TEST_ACTION_SPC and TEST_PAST_ACTION_SPC test either that the current action matches a given pattern, or that a given action has succeeded in the past, respectively. Each has an attached action_pattern * pointer.

§**5.** PHRASE_TO_DECIDE_IF_SPC is a usage of a phrase defined as "To decide if ...": as with other phrasal SPs, it has an attached invocation list.

§**6.** DESCRIPTION_SPC is the most complex species of all, and represents the most slippery idea: a noun phrase which describes certain values. It does not represent any given object or kind, even though it can in simple cases be a description so specific that it could only apply to a single object or kind, which may in practical terms be the same thing. We should probably regard a DESCRIPTION_SPC as defining a set of objects. But this is tricky for two reasons: first, the concept is broad enough to overlap in some cases with other types, which makes it ambiguous how we should parse certain text; and secondly, there are at least two different ways to manifest the idea of a set of objects in I6 at run-time, and we want to use both.

First, the parsing ambiguity. Given that a noun phrase consists of a noun as head-word together perhaps with 0 or more adjectives, and then with relative clauses added, there are clearly a wide range of possible outcomes. (And in fact in a few cases the head-word is itself optional: we can say "fixed in place scenery" even though this concatenates two either/or properties, which are in theory adjectival, though it doesn't look it here.) The various cases are:

(a) A single object unqualified by adjectives is always parsed to a constant value of KOV kova(OBJECT_TY), and so becomes a CONSTANT_SPC and not a DESCRIPTION_SPC. Thus, parsing treats the name of a specific object as a single value, not as a singleton set of that value.

(b) A single either/or property name is similarly parsed as a constant value of KOV kova(PROPERTY_TY).

(c) Otherwise, if there are no relative clauses attached, then the text is parsed as a DESCRIPTION_SPC with an attached docket, and the adjectives applied – which may be either/or properties, or adjectival enumerated values, or adjectival defined phrases – are accumulated in that docket.

(d) Otherwise, in the most complex cases, the text is parsed into a DESCRIPTION_SPC which has been "forced into propositional form", that is, we regard it as a set

$$\{x \mid P(x)\}$$

where P is a predicate calculus proposition with one free variable, and we record P in the proposition field of the SP.

We can convert format (c) to (d) easily, but vice versa is generally speaking impossible, and we never try. It might therefore seem easier to use format

(d) all of the time, but this would be a nuisance when trying to decide whether one description D_1 logically contains another, D_2 – something we need to do a lot of when sorting rules in specificity order. So in practice we prefer format (c) given the option.

Secondly, the compilation ambiguity. Used as a condition, a `DESCRIPTION_SPC` type compiles to a test of whether the currently understood object (the I6 value `self`, generally speaking) belongs to its set – i.e., matches the noun phrase – or not. But in order to make definitions like this one work, we also need to treat descriptions as values:

```
To decide which number is total (P - property) of (D - description):
```

The way this is done is that type-checking an actual `DESCRIPTION_SPC` type (say, "closed doors in lighted rooms") against the expectation of finding the data type `OBJECT_DESCRIPTION_TY` forces Inform to convert it to a constant of that type, compiling it as an iterator routine in I6 capable of (among other things) supplying the members in turn, and then using the address of this routine as the actual I6 value. (Constants with the KOV `OBJECT_DESCRIPTION_TY` cannot arise in any other way.)

```
void create_CONDITION_species(void) {
    type_ID_set_source_name(CONDITION_FMY, "CONDITION_FMY");
    type_ID_set_description(CONDITION_FMY, "yes or no");

    type_ID_permit_pair(CONDITION_FMY, DESCRIPTION_SPC,
        TYPE_PARSED_SPCONTEXT + PARSED_SPCONTEXT + TYPE_EXPECTED_SPCONTEXT +
        TYPE_FOUND_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(DESCRIPTION_SPC, "a description of an object");
    type_ID_set_source_name(DESCRIPTION_SPC, "DESCRIPTION_SPC");
    type_ID_set_flag(CONDITION_FMY, PROPOSITION_SPCFLAG + DOCKET_SPCFLAG);
}
```

The function create_CONDITION_species is called from 7/tids.

§**7.** Now some creator routines. `new_CONDITION_spec` is actually used only as a way to park time periods during meaning list construction; it doesn't generate SPs which persist later on.

```
specification *new_CONDITION_spec(time_period *tp) {
    specification *spec = spec_new(CONDITION_FMY, UNKNOWN);
    spec_set_condition_tense(spec, tp);
    return spec;
}
```

The function new_CONDITION_spec is called from 5/ml.

§**8.** Whereas this is used for type-checking:

```
specification *new_generic_CONDITION_type(void) {
    specification *spec = new_CONDITION_spec(NULL);
    spec_make_generic(spec);
    return spec;
}
```

The function new_generic_CONDITION_type is called from 7/tc, 9/scene and 11/ap.

§**9.** So, some more specific creators. The operators are easy:

```
specification *new_LOGICAL_AND_spec(specification *spec1, specification *spec2) {
    specification *spec = spec_new(CONDITION_FMY, LOGICAL_AND_SPC);
    spec_set_argument(spec, 0, spec1);
    spec_set_argument(spec, 1, spec2);
    return spec;
}
specification *new_LOGICAL_OR_spec(specification *spec1, specification *spec2) {
    specification *spec = spec_new(CONDITION_FMY, LOGICAL_OR_SPC);
    spec_set_argument(spec, 0, spec1);
    spec_set_argument(spec, 1, spec2);
    return spec;
}
```

The function new_LOGICAL_AND_spec is called from 5/mlc.
The function new_LOGICAL_OR_spec is called from 5/mlc.

§**10.** Testing propositions is also straightforward. There's no creator for `NOW_PREPOSITION_SPC`, since this is formed only by coercion of one of these.

```
specification *new_TEST_PROPOSITION_spec(pcalc_prop *prop) {
    specification *spec = spec_new(CONDITION_FMY, TEST_PROPOSITION_SPC);
    spec_set_proposition(spec, prop);
    return spec;
}
```

The function new_TEST_PROPOSITION_spec is called from 5/mlc.

§**11.** The option number here is actually 2^i, where $0 \leq i < 15$. This is just exactly feasible, since the specification data field is 16 bits wide.

```
specification *new_TEST_PHRASE_OPTION_spec(int opt_num) {
    specification *spec = spec_new(CONDITION_FMY, TEST_PHRASE_OPTION_SPC);
    spec_set_data(spec, PHRASE_OPTION_SPDATA, opt_num);
    return spec;
}
```

The function new_TEST_PHRASE_OPTION_spec is called from 5/ml.

§**12.** Past and present action tests have the pattern as an attachment:

```
specification *new_TEST_ACTION_spec(action_pattern *ap) {
    specification *spec = spec_new(CONDITION_FMY, TEST_ACTION_SPC);
    if (ap) ATTACH_TO_SPEC(spec, action_pattern, ap);
    return spec;
}
specification *new_TEST_PAST_ACTION_spec(action_pattern *ap) {
    specification *spec = spec_new(CONDITION_FMY, TEST_PAST_ACTION_SPC);
    if (ap) ATTACH_TO_SPEC(spec, action_pattern, ap);
    return spec;
}
```

The function new_TEST_ACTION_spec is called from 5/ml, 5/tandv and 12/phtd.
The function new_TEST_PAST_ACTION_spec is called from 5/ml.

§**13.** All phrasal specifications need to start with an attached empty invocation list, and this is no exception:

```
specification *new_PHRASE_TO_DECIDE_IF_spec(void) {
    specification *spec = spec_new(CONDITION_FMY, PHRASE_TO_DECIDE_IF_SPC);
    spec_create_invocation_list(spec);
    return spec;
}
```

The function new_PHRASE_TO_DECIDE_IF_spec is called from 5/mlc.

§**14.** And that leaves descriptions. Recall that these *either* have a docket *or* a proposition, with just one exception: a description meaning "any object at all" is allowed to have neither. This is because the empty proposition is universally true (see Chapter 6).

It follows that the bare result of calling the following routine is indeed a legal description, but not a very useful one. What generally happens is that the caller subsequently tacks on a docket or a preposition to narrow it down.

```
specification *new_DESCRIPTION_spec(void) {
    specification *spec = spec_new(CONDITION_FMY, DESCRIPTION_SPC);
    return spec;
}
```

The function new_DESCRIPTION_spec is called from 5/mlc and 11/ap.

§**15.** Since, in principle, any condition might also have a time period attached to it, we need a follow-up routine to attach this as necessary to a newly created condition:

```
void spec_attach_tense(specification *spec, int t) {
    if (spec_get_condition_tense(spec) == NULL)
        spec_set_condition_tense(spec, store_tp(new_time_period()));
    tp_set_tense(spec_get_condition_tense(spec), t);
}
```

The function spec_attach_tense is called from 5/mlc.

§**16. Coercions.** Recall that the following is the only way `NOW_PROPOSITION_SPC` can come into being:

```
void coerce_TEST_PROPOSITION_to_NOW_PROPOSITION(specification *spec) {
    if (spec == NULL) internal_error("can't coerce null type");
    if (species_is(spec, TEST_PROPOSITION_SPC))
        spec_coerce_to(spec, CONDITION_FMY, NOW_PROPOSITION_SPC);
    else internal_error("tried coerce_TEST_PROPOSITION_to_NOW_PROPOSITION inapplicably");
}
```

The function coerce_TEST_PROPOSITION_to_NOW_PROPOSITION is called from 7/tc.

§**17.** In general we represent "a number" as a generic constant value with KOV "number", but once we want to apply an adjective to it, say "even", we make something complex enough to become a description. So the following routine makes the DESCRIPTION_SPC specification, all ready for "even" to be added to its docket.

```
void coerce_generic_CONSTANT_to_DESCRIPTION(specification *spec) {
    if (spec == NULL) internal_error("can't coerce null type");
    if (spec_is_generic_CONSTANT(spec)) {
        kind_of_value *kov = spec_get_kind_of_value(spec);
        spec_coerce_to(spec, CONDITION_FMY, DESCRIPTION_SPC);
        spec_set_described_kov(spec, kov);
        /* empty_adjective_list(spec);
        spec_set_proposition(spec, NULL); */
        spec_make_actual(spec);
        return;
    }
    internal_error("tried coerce_generic_CONSTANT_to_DESCRIPTION inapplicably");
}
```

The function coerce_generic_CONSTANT_to_DESCRIPTION is called from 7/tc.

§**18. Testing.** A tricky test of a DESCRIPTION: does this consist *exactly* of "all objects of a given kind"? Qualification by adjective or proposition is not permitted.

```
int spec_is_DESCRIPTION_of_kind(specification *spec) {
    if (species_is(spec, DESCRIPTION_SPC) == FALSE) return FALSE;
    if (spec_is_qualified_DESCRIPTION(spec)) return FALSE;
    if (spec_get_described_object(spec)) return FALSE;
    return TRUE;
}
```

The function spec_is_DESCRIPTION_of_kind is called from 12/phtd.

§**19.** DESCRIPTIONs are "qualified" when adjectives, or relative clauses, make them dependent on context. For instance, "a vehicle" is unqualified, but "an even number" or "a vehicle in Trafalgar Square" are qualified – a given value V might satisfy the description at some times but not others during play.

```
int spec_is_qualified_DESCRIPTION(specification *spec) {
    if ((species_is(spec, DESCRIPTION_SPC)) &&
        ((spec_get_proposition(spec)) || (number_of_adjectives_applied_to(spec) > 0)))
        return TRUE;
    return FALSE;
}
```

The function spec_is_qualified_DESCRIPTION is called from 5/aph, 7/tc and 13/tfg.

§**20.** Given a DESCRIPTION specification, constrain it further by making it belong to the new domain supplied, which might be a kind or a specific object. If this is impossible because its existing domain is incompatible with its new one, cancel the specification out to UNKNOWN.

```
void restrict_DESCRIPTION_domain(specification *spec, world_object *new_domain) {
    if (new_domain == NULL) return;
    world_object *current_domain = spec_get_described_object(spec);
    if (current_domain == NULL) current_domain = spec_get_described_kind(spec);
    if (current_domain == NULL) current_domain = new_domain;
    else if ((current_domain == new_domain) || (wo_of_kind(current_domain, new_domain)))
        ;
    else if (wo_of_kind(new_domain, current_domain))
        current_domain = new_domain;
    else {
        if (new_domain != kind_room) coerce_spec_to_UNKNOWN(spec);
        return;
    }
    spec_set_described_object(spec, NULL);
    spec_set_described_kind(spec, NULL);
    if (current_domain) {
        if (current_domain->kind_flag) spec_set_described_kind(spec, current_domain);
        else spec_set_described_object(spec, current_domain);
    }
}
```

The function restrict_DESCRIPTION_domain is called from 5/mlc.

§21. Pretty-printing.

```
void write_CONDITION_out_in_English(specification *spec, char *text) {
    switch (spec_get_species(spec)) {
        case PHRASE_TO_DECIDE_IF_SPC:
            sprintf(text+strlen(text), "a yes or no question");
            break;
        case DESCRIPTION_SPC:
            sprintf(text+strlen(text), "an object matching a description");
            break;
        default:
            sprintf(text+strlen(text), "a condition");
    }
}
```

The function write_CONDITION_out_in_English is called from 7/spec.

§**22.** And the log:

```
void log_CONDITION_spec_details(specification *spec) {
    if (spec_test_flag(spec, CONDITION_NEGATED_SPFLAG)) LOG("(negated)");
    if (spec_get_condition_tense(spec)) log_time_period(spec_get_condition_tense(spec));
    if (species_is(spec, DESCRIPTION_SPC)) {
        adjective_list_entry *ale;
        int i = 0;
        LOOP_THROUGH_ADJECTIVE_LIST(ale, spec) {
            if (i == 0) LOG("(adjectives:"); else LOG(",");
            LOG("$r", ale);
            i++;
        }
        if (i > 0) LOG(")");
        if (spec_get_described_object(spec)) LOG("(object $O)", spec_get_described_object(spec));
        if (spec_get_described_kind(spec)) LOG("(kind $O)", spec_get_described_kind(spec));
        if (spec_get_described_kov(spec)) LOG("(KOV $u)", spec_get_described_kov(spec));
        if (spec_get_proposition(spec)) LOG("(such that $D)", spec_get_proposition(spec));
    }
}
```

The function log_CONDITION_spec_details is called from 7/spec.

§**23. Comparing.** Descriptions are used to set out the domain of rules, and rules have to be sorted in order of narrowness, which means we need a way to tell which is narrower of two descriptions.

```
int compare_specificity_of_DESCRIPTIONs(specification *spec1, specification *spec2) {
    ⟨If either of these two descriptions has a proposition, then propositional size decides it 24⟩;
    ⟨If the typechecker recognises one as properly within the other, then that's the more specific 25⟩;
    ⟨If either of these two descriptions have adjectives in their dockets, adjective count decides it 26⟩;
    return 0;
}
```

The function compare_specificity_of_DESCRIPTIONs is called from 7/spec.

§**24.** We have to be careful here because some descriptions use a docket, some a proposition, to represent the same conceptual information. However, since propositional form is only used when docket form can't hold so complex a condition, we will follow the rule that *a proposition beats a docket*. Thus any noun phrase containing a relative clause is deemed more specific than a noun phrase without.

That leaves us deciding which of two propositions is more specific. To perform that test perfectly, we would need a way to determine, given two proposition A and B, whether one implied the other or not. Since predicate calculus is complete, and our domains are mostly finite, there do in fact exist (slow and difficult) algorithms which could determine this. But there would be real problems with larger domains not amenable to model-checking, such as "number", and anyway – why not cheat?

Proposition length is admittedly a crude measure, but because of the fact that both propositions have come from the same generative algorithm, it does indeed turn out that $A \Rightarrow B$ means $\ell(A) \geq \ell(B)$, where ℓ is the number of atoms in the proposition. So we simply use it as a sorting key.

⟨If either of these two descriptions has a proposition, then propositional size decides it 24⟩ ≡

```
    int len1 = prop_length(spec_get_proposition(spec1));
    int len2 = prop_length(spec_get_proposition(spec2));
    if ((len1 > 0) || (len2 > 0)) {
        LOGIF(SPECIFICITIES,
            "Test %d: Comparing specificity of props:\n(%d) $D\n(%d) $D\n",
```

```
            cco, len1, spec_get_proposition(spec1), len2, spec_get_proposition(spec2));
    }
    if (len1 > len2) return 1;
    if (len1 < len2) return -1;
```

This code is used in §23.

§**25.**

⟨If the typechecker recognises one as properly within the other, then that's the more specific 25⟩ ≡

```
    if (can_we_match_value_descriptions(spec1, spec2) == ALWAYS_MATCH) {
        if (can_we_match_value_descriptions(spec2, spec1) != ALWAYS_MATCH) return 1;
    } else {
        if (can_we_match_value_descriptions(spec2, spec1) == ALWAYS_MATCH) return -1;
    }
```

This code is used in §23.

§**26.**

⟨If either of these two descriptions have adjectives in their dockets, adjective count decides it 26⟩ ≡

```
    int count1 = number_of_adjectives_applied_to(spec1);
    int count2 = number_of_adjectives_applied_to(spec2);
    if (count1 > count2) return 1;
    if (count1 < count2) return -1;
```

This code is used in §23.

§**27.** We also need a way of determining which of two conditions is more complex, so that action-based rules with "when..." clauses tacked on can be sorted: the following is used to compare such "when..." conditions. Again it is essentially a counting argument. Long conditions, with many clauses, beat shorter ones.

```
int compare_specificity_of_CONDITIONs(specification *spec1, specification *spec2) {
    int count1 = count_CONDITION_coverage(spec1);
    int count2 = count_CONDITION_coverage(spec2);
    if (count1 > count2) return 1;
    if (count1 < count2) return -1;
    return 0;
}
```

The function compare_specificity_of_CONDITIONs is called from 11/ap.

§**28.** The only justification for the following complexity score is that it does seem to accord well with what people expect. (There's clearly no theoretically perfect way to define complexity of conditions in a language as complex as Inform; this bit of scruffy, rather than neat, logic will have to do.)

```
int count_CONDITION_coverage(specification *spec) {
    if (spec == NULL) return 0;
    if (family_is(spec, CONDITION_FMY) == FALSE) return 1;
    switch (spec_get_species(spec)) {
        case LOGICAL_AND_SPC:
            return count_CONDITION_coverage(spec_get_argument(spec, 0))
                + count_CONDITION_coverage(spec_get_argument(spec, 1));
        case LOGICAL_OR_SPC:
            return -1;
        case TEST_PROPOSITION_SPC:
            return prop_length(spec_get_proposition(spec));
        case PHRASE_TO_DECIDE_IF_SPC:
        case TEST_PHRASE_OPTION_SPC:
        case TEST_ACTION_SPC:
        case TEST_PAST_ACTION_SPC:
            return 1;
    }
    return 0;
}
```

§**29. Compiling.** Conditions of course cannot be evaluated, so:

```
kind_of_value *kov_when_CONDITION_is_evaluated(specification *spec) {
    return NULL;
}
```

The function kov_when_CONDITION_is_evaluated is called from 7/spec.

§**30.** We clear two oddball cases out of the way, and then for the most part we delegate to potent routines elsewhere. Note that in some situations a valid I6 condition must be enclosed in round brackets, and that a redundant pair of brackets never does any harm; so we always compile one.

```
void compile_CONDITION_spec(OUTPUT_STREAM, specification *spec_found) {
    if (species_is(spec_found, NOW_PROPOSITION_SPC))
        ⟨Compile the not-really-conditional "now" propositions 31⟩;
    if (spec_get_condition_tense(spec_found))
        ⟨The use of a past tense pre-empts condition compilation 32⟩;
    WRITE("(");
    if (spec_test_flag(spec_found, CONDITION_NEGATED_SPFLAG)) WRITE("~~(");
    switch (spec_get_species(spec_found)) {
        case DESCRIPTION_SPC: compile_test_of_subst__v(OUT, spec_found); break;
        case TEST_PROPOSITION_SPC:
            compile_test_of_proposition(OUT, NULL, spec_get_proposition(spec_found));
            break;
        case LOGICAL_AND_SPC: case LOGICAL_OR_SPC: ⟨Compile a logical operator 33⟩; break;
        case TEST_ACTION_SPC:
            compile_action_pattern_match(OUT,
                *(RETRIEVE_FROM_SPEC(spec_found, action_pattern)), FALSE);
            break;
```

```
        case TEST_PAST_ACTION_SPC:
            compile_past_tense_action(OUT, RETRIEVE_FROM_SPEC(spec_found, action_pattern));
            break;
        case TEST_PHRASE_OPTION_SPC: ⟨Compile a phrase option test 34⟩; break;
        case PHRASE_TO_DECIDE_IF_SPC:
            compile_invocational_phrase(OUT, spec_found);
            break;
    }
    if (spec_test_flag(spec_found, CONDITION_NEGATED_SPFLAG)) WRITE(")");
    WRITE(")");
}
```

The function compile_CONDITION_spec is called from 7/cfsp.

§**31.** In fact, "now" propositions are never empty, but there's nothing in principle wrong with asserting that the universally true proposition is henceforth to be true, so we simply compile empty code in that case.

⟨Compile the not-really-conditional "now" propositions 31⟩ ≡

```
    if (spec_get_proposition(spec_found))
        compile_now_proposition(OUT, spec_get_proposition(spec_found));
    return;
```

This code is used in §30.

§**32.** A condition SP has a valid `condition_tense` time period field only if the tense in question is not the present. What happens is basically that we defer evaluating the condition to another part of the I6 source text, and here write something different. Tenses therefore pre-empt the rest of condition compilation.

⟨The use of a past tense pre-empts condition compilation 32⟩ ≡

```
    compile_past_tense_condition(OUT, *(spec_get_condition_tense(spec_found)),
        spec_copy(spec_found));
    return;
```

This code is used in §30.

§**33.** An easy case, running straight out to I6 operators:

⟨Compile a logical operator 33⟩ ≡

```
    if (spec_get_argc(spec_found) != 2)
        internal_error("Compiled malformed CONDITION/AND SP");
    specification *left_operand = spec_get_argument(spec_found, 0);
    specification *right_operand = spec_get_argument(spec_found, 1);
    if ((left_operand == NULL) || (right_operand == NULL))
        internal_error("Compiled CONDITION/AND with LHS operands");
    spec_compile(OUT, left_operand);
    if (species_is(spec_found, LOGICAL_AND_SPC)) WRITE(" && ");
    if (species_is(spec_found, LOGICAL_OR_SPC)) WRITE(" || ");
    spec_compile(OUT, right_operand);
```

This code is used in §30.

§**34.** Phrase options are stored as bits in a 16-bit map, so that each individual option is a power of two from 2^0 to 2^15. We test if this is valid by performing logical-and against the I6 local variable `phrase_options`, which exists if and only if the enclosing I6 routine takes phrase options. The type-checker won't allow these specifications to be compiled anywhere else.

⟨Compile a phrase option test 34⟩ ≡

```
WRITE("phrase_options & %d", spec_get_data(spec_found, PHRASE_OPTION_SPDATA));
```

This code is used in §30.

§**35. Dockets attached to DESCRIPTION types.** A docket takes a modest amount of storage, so is allocated only when needed; of course most specifications are not DESCRIPTIONs, and will certainly never need one. The docket is created only when there's a need to store some non-trivial data in one.

```
void spec_clear_docket(specification *spec) {
    empty_adjective_list(spec);
    spec_set_described_kind(spec, NULL);
    spec_set_described_kov(spec, NULL);
    spec_set_described_object(spec, NULL);
    description_docket *dd = spec_get_docket(spec);
    dd->calling_w1 = -1;
    dd->calling_w2 = -1;
}
description_docket *spec_find_docket(specification *spec, int create_if_necessary) {
    if (spec == NULL) {
        if (create_if_necessary) internal_error("creating docket for null type");
        return NULL;
    }
    description_docket *dd = spec_get_docket(spec);
    if (dd == NULL) {
        if (create_if_necessary == FALSE) return NULL;
        dd = CREATE(description_docket);
        spec_set_docket(spec, dd);
        spec_clear_docket(spec);
        dd->quant = NULL;
        dd->quant_parameter = 0;
    }
    return dd;
}
```

§**36.** Because a specification structure contains a pointer to a docket, copying the specification bitwise leaves two different specifications pointing to the same docket. That very rarely matters, but in cases where it might, we must copy thus:

```
specification *spec_copy_and_copy_docket(specification *spec) {
    if (spec == NULL) return NULL;
    specification *nts = spec_copy(spec);
    if (spec_get_docket(spec)) {
        description_docket *ndd = CREATE(description_docket);
        spec_set_docket(nts, ndd);
        *ndd = *(spec_get_docket(spec));
    }
    return nts;
}
```

The function spec_copy_and_copy_docket is called from 11/los.

§**37.** The crucial moment in the life of any interesting DESCRIPTION comes when its docket is converted to a proposition – as it must be in order for it to be asserted true about the model world, or to be compiled in a "now".

```
void spec_convert_docket_to_proposition(specification *spec) {
    pcalc_prop *prop = prop_from_spec(spec, FALSE);
    spec_set_proposition(spec, prop);
    spec_clear_docket(spec);
}
```

The function spec_convert_docket_to_proposition is called from 6/defer, 8/refpt, 11/ap and 12/cinv.

§**38.** And now, many dull but straightforward routines for handling the docket's contents.

```
int number_of_adjectives_applied_to(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) return 0;
    return dd->no_adjectives_applied;
}
adjective_list_entry *first_adjective_list_entry(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if ((dd == NULL) || (dd->no_adjectives_applied == 0))
        internal_error("adjective list has no entries");
    return dd->adjectives_applied;
}
void empty_adjective_list(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd) {
        dd->adjectives_applied = NULL;
        dd->no_adjectives_applied = 0;
    }
}
void add_to_adjective_list(adjective_list_entry *ale, specification *spec) {
    description_docket *dd = spec_find_docket(spec, TRUE);
    dd->no_adjectives_applied++;
    ale->next = NULL;
```

```
    adjective_list_entry *last = dd->adjectives_applied;
    if (last == NULL) { dd->adjectives_applied = ale; return; }
    while (last->next) last = last->next;
    last->next = ale;
}

int types_have_same_adjective_list(specification *spec1, specification *spec2) {
    description_docket *dd1 = spec_find_docket(spec1, FALSE);
    description_docket *dd2 = spec_find_docket(spec2, FALSE);
    if ((dd1 == NULL) && (dd2 == NULL)) return TRUE;
    if ((dd1) && (dd2) && (dd1->adjectives_applied == dd2->adjectives_applied)) return TRUE;
    return FALSE;
}
```

The function number_of_adjectives_applied_to is called from 5/mlc, 7/tc, 8/refpt, 8/assem, 8/knowp, 9/pp, 10/tab, 11/act, 11/av, 12/phtd, 12/rb and 13/tfg.
The function first_adjective_list_entry is called from 7/tc, 8/refpt, 10/tab and 13/tfg.
The function add_to_adjective_list is called from 5/mlc.

§39. Quantification.

```
void spec_attach_quantifier(specification *spec, quantifier *q, int par) {
    description_docket *dd = spec_find_docket(spec, TRUE);
    dd->quant = q;
    dd->quant_parameter = par;
}

quantifier *spec_get_quantifier(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) return NULL;
    return dd->quant;
}

int spec_get_quantification_parameter(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) return 0;
    return dd->quant_parameter;
}
```

The function spec_attach_quantifier is called from 5/mlc.
The function spec_get_quantifier is called from 6/pform and 8/refpt.
The function spec_get_quantification_parameter is called from 6/pform, 8/refpt, 8/creat and 8/mass.

§40. Callings.

```
void spec_attach_calling(specification *spec, int c1, int c2) {
    description_docket *dd = spec_find_docket(spec, TRUE);
    dd->calling_w1 = c1;
    dd->calling_w2 = c2;
}
void spec_get_calling(specification *spec, int *c1, int *c2) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) { *c1 = -1; *c2 = -1; }
    else { *c1 = dd->calling_w1; *c2 = dd->calling_w2; }
}
void spec_clear_calling(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd) { dd->calling_w1 = -1; dd->calling_w2 = -1; }
}
int spec_makes_callings(specification *spec) {
    if (spec == NULL) return FALSE;
    int c1, c2;
    spec_get_calling(spec, &c1, &c2);
    if (c1 >= 0) return TRUE;
    return FALSE;
}
```

The function spec_attach_calling is called from 5/mlc.
The function spec_get_calling is called from 6/pform and 11/ap.
The function spec_clear_calling is called from 11/los.
The function spec_makes_callings is called from 7/spec and 11/ap.

§41. The kind.

```
void spec_set_described_kov(specification *spec, kind_of_value *kov) {
    description_docket *dd = spec_find_docket(spec, TRUE);
    dd->specific_kov = kov;
}
kind_of_value *spec_get_described_kov(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) return NULL;
    return dd->specific_kov;
}
void spec_set_described_kind(specification *spec, world_object *k) {
    description_docket *dd = spec_find_docket(spec, TRUE);
    dd->specific_kind = k;
}
world_object *spec_get_described_kind(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) return NULL;
    return dd->specific_kind;
}
void spec_set_described_object(specification *spec, world_object *wo) {
    description_docket *dd = spec_find_docket(spec, TRUE);
    dd->specific_object = wo;
```

```
}
world_object *spec_get_described_object(specification *spec) {
    description_docket *dd = spec_find_docket(spec, FALSE);
    if (dd == NULL) return NULL;
    return dd->specific_object;
}
```

The function spec_set_described_kov is called from 5/mlc.

The function spec_get_described_kov is called from 5/aph, 5/mlc, 6/pform, 7/tc, 8/refpt, 8/creat, 11/ap, 12/phud, 12/phtd, 12/cinv and 13/gtok.

The function spec_set_described_kind is called from 5/mlc and 11/ap.

The function spec_get_described_kind is called from 2/prob2, 5/aph, 5/mlc, 6/pform, 6/asp, 7/tc, 8/refpt, 8/creat, 8/assem, 9/pp, 10/tab, 10/isin, 11/act, 11/av, 12/phtd, 12/cinv, 12/rb and 13/tfg.

The function spec_set_described_object is called from 5/mlc.

The function spec_get_described_object is called from 2/prob2, 5/mlc, 6/pform, 6/asp, 7/specv, 8/refpt, 10/tab, 10/isin, 11/ap, 12/phtd and 13/tfg.

§**42.** Adjective lists are attached to descriptions as part of the docket: thus "lockable open door" generates a SP including the adjective list (lockable, open). It's often convenient to loop through the adjectives for a given SP:

```
define LOOP_THROUGH_ADJECTIVE_LIST(ale, spec)
    for (ale = (spec_find_docket(spec, FALSE))?((spec_find_docket(spec, FALSE))->adjectives_applied):NULL;
        ale; ale=ale->next)
```

```
adjective_list_entry *new_adjective_list_entry(adjectival_phrase *aph, int pos) {
    adjective_list_entry *ale = CREATE(adjective_list_entry);
    ale->ref_to = aph;
    ale->ref_positive = pos;
    ale->next = NULL;
    return ale;
}
void log_adjective_list_entry(adjective_list_entry *ale) {
    adjectival_phrase *aph = get_adjective_from_list_entry(ale);
    if (ale->ref_positive == FALSE) LOG("~");
    LOG("<adj:$W>", aph->word_ref1, aph->word_ref2);
}
adjective_list_entry *copy_adjective_list_entry(adjective_list_entry *ale_from) {
    return new_adjective_list_entry(ale_from->ref_to, ale_from->ref_positive);
}
adjectival_phrase *get_adjective_from_list_entry(adjective_list_entry *ale) {
    if (ale == NULL) return NULL;
    return ale->ref_to;
}
int adjective_used_positively(adjective_list_entry *ale) {
    if (ale == NULL) internal_error("null adjective tested for positivity");
    return ale->ref_positive;
}
```

The function new_adjective_list_entry is called from 5/mlc, 6/term and 6/aprop.

The function log_adjective_list_entry is called from 2/dl.

The function copy_adjective_list_entry is called from 5/mlc.

The function get_adjective_from_list_entry is called from 5/mlc, 6/term, 6/aprop, 6/prop, 6/pform, 6/tcpr, 6/asp, 6/atoms, 7/tc, 8/refpt, 8/imp, 10/tab and 13/tfg.

The function adjective_used_positively is called from 6/aprop, 6/pform, 6/asp, 6/atoms, 8/refpt and 13/tfg.

COMMAND Specifications 7/cmsp

Purpose

Documentation on and functions handling specifications which fall into the COMMAND family.

7/cmsp.§1-8 Creation; §9 Coercion; §10 Pretty-printing; §11-19 Compilation

---

Definitions

---

§**1. Creation.** There are a variety of specific types here, but most are variations on a theme: the phrase used as part of the definition of a rule or another phrase. For instance, in the rule

```
Before looking: say "You blink in surprise."
```

the test

```
say "You blink in surprise."
```

is parsed to an actual `TO_PHRASE_SPC` specification.

§**2.** `TO_PHRASE_SPC` has an invocation list attached, as all phrasal specifications do.

§**3.** `END_BLOCK_SPC` signifies an "end if", "end repeat", etc., phrase ending a block of code. Such phrases are unambiguous and do not in any case correspond to formal definitions (i.e., there is no line in the Standard Rules reading "To end if: ..."), so they are represented by this species rather than `TO_PHRASE_SPC`. In order to distinguish a use of "end if" from an "end while", or some other, a pointer is attached to the `phrase` which is ending ("if", "while" or whatever).

§**4.** `OTHERWISE_SPC` signifies an "otherwise", and since this applies only to "if" constructions, there is no need for any pointer this time.

§**5.** `CASE_SPC` signifies a case in a switch statement. This can either have a single argument, the value for this case, or no arguments, marking it out as the default case.

§**6.** `RULEBOOK_OUTCOME_PHRASE_SPC` is a rulebook outcome – such as "persuasion succeeds" in the persuasion rules – used as if it were a phrase: it means, of course, stop the rulebook here and use this as the outcome. It can only be parsed in rules belonging to that rulebook, so there is no danger of it being used in a phrase to decide a value or an outcome. A pointer to the named outcome in question is attached.

§**7.** TRY_ACTION_SPC is the cuckoo in the nest, and there are arguments for it being a form of CONDITION rather than COMMAND. Strictly speaking, it represents not a phrase like

try eating the buttercup;

but rather the action described, viz., "eating the buttercup". This is parsed as a TEST_ACTION_SPC – where it is indeed a condition – but is converted into a TRY_ACTION_SPC on being type-checked against a generic TRY_ACTION_SPC specification. For this to succeed, the action must be exact in every way, so relatively few TRY_ACTION_SPC types chosen at random would be eligible. All the same, that makes it sound like a species of CONDITION, so why isn't it? The answer really is that it compiles into I6 code which executes in a void context to perform the action in question, not into anything which is syntactically an I6 condition.

```
void create_COMMAND_species(void) {
    type_ID_set_description(COMMAND_FMY, "a phrase");
    type_ID_set_source_name(COMMAND_FMY, "COMMAND_FMY");
    type_ID_set_parsing_names(COMMAND_FMY, phrase_V, phrases_V);
    type_ID_permit_pair(COMMAND_FMY, UNKNOWN,
        TYPE_PARSED_SPCONTEXT + TYPE_EXPECTED_SPCONTEXT);
    type_ID_permit_pair(COMMAND_FMY, TO_PHRASE_SPC,
        PARSED_SPCONTEXT + TYPE_PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(TO_PHRASE_SPC, "no value resulting");
    type_ID_set_source_name(TO_PHRASE_SPC, "TO_PHRASE_SPC");
    type_ID_set_flag(TO_PHRASE_SPC, PHRASAL_SPCFLAG + INVLIST_SPCFLAG);
    type_ID_permit_pair(COMMAND_FMY, OTHERWISE_SPC,
        PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(OTHERWISE_SPC, "a phrase between blocks of phrases");
    type_ID_set_source_name(OTHERWISE_SPC, "OTHERWISE_SPC");
    type_ID_set_flag(OTHERWISE_SPC, PHRASAL_SPCFLAG);
    type_ID_permit_pair(COMMAND_FMY, CASE_SPC,
        PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(CASE_SPC, "a case in an 'if X is...' switch");
    type_ID_set_source_name(CASE_SPC, "CASE_SPC");
    type_ID_set_flag(CASE_SPC, PHRASAL_SPCFLAG + ARGUMENTS_SPCFLAG);
    type_ID_permit_pair(COMMAND_FMY, END_BLOCK_SPC,
        PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(END_BLOCK_SPC, "a phrase ending a block of phrases");
    type_ID_set_source_name(END_BLOCK_SPC, "END_BLOCK_SPC");
    type_ID_set_flag(END_BLOCK_SPC, PHRASAL_SPCFLAG);
    type_ID_permit_pair(COMMAND_FMY, RULEBOOK_OUTCOME_PHRASE_SPC,
        PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT + TYPE_EXPECTED_SPCONTEXT +
        COMPILED_SPCONTEXT);
    type_ID_set_description(RULEBOOK_OUTCOME_PHRASE_SPC,
        "a phrase providing an outcome to a rulebook");
    type_ID_set_source_name(RULEBOOK_OUTCOME_PHRASE_SPC,
        "RULEBOOK_OUTCOME_PHRASE_SPC");
    type_ID_set_flag(RULEBOOK_OUTCOME_PHRASE_SPC, PHRASAL_SPCFLAG);
    type_ID_permit_pair(COMMAND_FMY, TRY_ACTION_SPC,
        PARSED_SPCONTEXT + TYPE_PARSED_SPCONTEXT + TYPE_FOUND_SPCONTEXT +
        TYPE_EXPECTED_SPCONTEXT + COMPILED_SPCONTEXT);
    type_ID_set_description(TRY_ACTION_SPC, "an action");
    type_ID_set_parsing_names(TRY_ACTION_SPC, action_V, actions_V);
    type_ID_set_source_name(TRY_ACTION_SPC, "TRY_ACTION_SPC");
```

```
    type_ID_set_flag(TRY_ACTION_SPC, ARGUMENTS_SPCFLAG);
}
```

The function create_COMMAND_species is called from 7/tids.

§**8.** And the usual creator routines:

```
specification *new_COMMAND_spec(void) {
    specification *spec = spec_new(COMMAND_FMY, UNKNOWN);
    return spec;
}
specification *new_TO_PHRASE_spec(void) {
    specification *spec = spec_new(COMMAND_FMY, TO_PHRASE_SPC);
    spec_create_invocation_list(spec);
    return spec;
}
specification *new_OTHERWISE_spec(void) {
    specification *spec = spec_new(COMMAND_FMY, OTHERWISE_SPC);
    return spec;
}
specification *new_CASE_spec(specification *case_val) {
    specification *spec = spec_new(COMMAND_FMY, CASE_SPC);
    spec_set_argument(spec, 0, case_val);
    return spec;
}
specification *new_default_CASE_type(void) {
    specification *spec = spec_new(COMMAND_FMY, CASE_SPC);
    return spec;
}
specification *new_RULEBOOK_OUTCOME_COMMAND_spec(named_rulebook_outcome *nro) {
    specification *spec = spec_new(COMMAND_FMY, RULEBOOK_OUTCOME_PHRASE_SPC);
    ATTACH_TO_SPEC(spec, named_rulebook_outcome, nro);
    return spec;
}
specification *new_END_BLOCK_spec(phrase *ph) {
    specification *spec = spec_new(COMMAND_FMY, END_BLOCK_SPC);
    ATTACH_TO_SPEC(spec, phrase, ph);
    return spec;
}
```

The function new_COMMAND_spec is called from 12/cph.
The function new_TO_PHRASE_spec is called from 5/mlc.
The function new_OTHERWISE_spec is called from 5/mlc.
The function new_CASE_spec is called from 5/mlc.
The function new_default_CASE_type is called from 5/mlc.
The function new_RULEBOOK_OUTCOME_COMMAND_spec is called from 5/mlc.
The function new_END_BLOCK_spec is called from 5/mlc.

§**9. Coercion.** As noted above, TRY_ACTION_SPC specifications come into existence only through coercion:

```
void coerce_TEST_ACTION_to_TRY_ACTION(specification *spec,
    specification *nspec, specification *sspec, specification *aspec,
    int other_flag, action_name_list *anl) {
    if (spec == NULL) internal_error("coerce_TEST_ACTION_to_TRY_ACTION on NULL");
    spec_coerce_to(spec, COMMAND_FMY, TRY_ACTION_SPC);
    spec_set_argument(spec, 0, nspec);
    spec_set_argument(spec, 1, sspec);
    spec_set_argument(spec, 2, aspec);
    if (other_flag) spec_set_flag(spec, ACTION_FOR_OTHER_SPFLAG);
    else spec_clear_flag(spec, ACTION_FOR_OTHER_SPFLAG);
    ATTACH_TO_SPEC(spec, action_name_list, anl);
}
```

The function coerce_TEST_ACTION_to_TRY_ACTION is called from 11/ap.

§**10. Pretty-printing.** Was never so plain:

```
void write_COMMAND_out_in_English(specification *spec, char *text) {
    sprintf(text+strlen(text), "an instruction to do something");
}
void log_COMMAND_spec_details(specification *spec) {
}
```

The function write_COMMAND_out_in_English is called from 7/spec.
The function log_COMMAND_spec_details is called from 7/spec.

§**11. Compilation.** Some phrases do decide values, but those can't be compiled in a void context: they live in the VALUE family, not here. So:

```
kind_of_value *kov_when_COMMAND_is_evaluated(specification *spec) {
    return NULL;
}
```

The function kov_when_COMMAND_is_evaluated is called from 7/spec.

§**12.** So, then:

```
int compile_To_phrase_recursion_depth = 0;
void compile_COMMAND_spec(OUTPUT_STREAM, specification *spec_found) {
    switch (spec_get_species(spec_found)) {
        case CASE_SPC: ⟨Compile a switch case 15⟩;
        case END_BLOCK_SPC: ⟨Compile an "end..." 14⟩;
        case OTHERWISE_SPC: ⟨Compile an "otherwise" 13⟩;
        case RULEBOOK_OUTCOME_PHRASE_SPC: ⟨Compile a rulebook outcome 17⟩;
        case TO_PHRASE_SPC: ⟨Compile a usage of a "To..." phrase 16⟩;
        case TRY_ACTION_SPC: ⟨Compile a try of an action 18⟩;
    }
}
```

The function compile_COMMAND_spec is called from 7/cfsp.

§**13.** Because the type-checker works only locally, not at a level as large as an entire rule definition, there's no good way to issue this problem message at the type-checking stage. But it does no harm to leave it until now, anyway.

⟨Compile an "otherwise" 13⟩ ≡
```
    if (increment_otherwise_count() == 1) {
        sentence_problem(_P_(C7DoubleOtherwise),
            "that makes two unconditional 'otherwise' or 'else' clauses "
            "for this 'if'",
            "which is forbidden since 'otherwise' is meant to be a single "
            "(optional) catch-all clause at the end.");
    }
    WRITE("} else {\n");
    return;
```

This code is used in §12.

§**14.**

⟨Compile an "end..." 14⟩ ≡
```
    WRITE("}\n");
    if (ct_variables_saved_in_this_block() >= 0) WRITE("@pull ct_1; @pull ct_0;");
    close_code_block();
    return;
```

This code is used in §12.

§**15.** Switch statements in I6 look much like those in C, but are written without the ceaseless repetition of the keyword "case". Thus, `15:` does what `case 15:` would do in C. But `default:` is the same in both.

⟨Compile a switch case 15⟩ ≡
```
    if ((spec_get_argc(spec_found) != 0) && (spec_get_argc(spec_found) != 1))
        internal_error("Compiled malformed CASE SP");
    if (increment_otherwise_count() != 0) WRITE(";\n");
    if (spec_get_argc(spec_found) == 0) WRITE("default");
    else spec_compile(OUT, spec_get_argument(spec_found, 0));
    WRITE(":\n");
    return;
```

This code is used in §12.

§**16.** The following problem messages are issued here rather than in typechecking because, in fact, the constructions in question "ought" to be legal – from a formal point of view they are reasonable. But they lead to horrible ambiguities which end up being resolved in ways the author doesn't expect, or so experience showed. Our mechanism for blocking them is admittedly ugly, but works nicely in practice.

⟨Compile a usage of a "To..." phrase 16⟩ ≡

```
compile_To_phrase_recursion_depth++;
if ((compile_To_phrase_recursion_depth > 1) &&
    (detect_control_structure(spec_found->word_ref1, spec_found->word_ref2))) {
    sentence_problem(_P_(C7BlockWithinNonblock),
        "structural phrases like 'if', 'repeat', 'while' or 'otherwise' "
        "can't be used as part of the abbreviated form of other structural "
        "phrases",
        "so for instance 'if in darkness, repeat with X running through rooms' "
        "is not allowed because the 'repeat' is too important a phrase to be "
        "put at the end of a simple 'if' like this. Instead, the 'if' must be "
        "written out in full, so for instance 'if in darkness begin; "
        "repeat ... begin; ...; end repeat; end if;' would be fine.");
}
if ((is_otherwise_if(spec_found->word_ref1, spec_found->word_ref2)) &&
    (read_otherwise_count() > 0)) {
    sentence_problem(_P_(C7OtherwiseIfAfterOtherwise),
        "this seems to be misplaced since it is out of sequence within its 'if'",
        "with an 'otherwise if...' coming after the more general 'otherwise' "
        "rather than before. (If there's an 'otherwise' clause, it has to be "
        "the last clause of the 'if'.)");
}
compile_invocational_phrase(OUT, spec_found);
compile_To_phrase_recursion_depth--;
return;
```

This code is used in §12.

§**17.**

⟨Compile a rulebook outcome 17⟩ ≡

```
rb_compile_outcome(OUT, RETRIEVE_FROM_SPEC(spec_found, named_rulebook_outcome));
return;
```

This code is used in §12.

§**18.** `TryAction` is a template routine with four arguments: a bitmap of flags about the nouns and actor, the actor object, and the noun and second noun values.

⟨Compile a try of an action 18⟩ ≡

```
    if (spec_get_argc(spec_found) != 3) internal_error("Compiled malformed ACTION SP");
    specification *spec0 = spec_get_argument(spec_found, 0);                    the noun
    specification *spec1 = spec_get_argument(spec_found, 1);                    the second noun
    specification *spec2 = spec_get_argument(spec_found, 2);                    the actor
    if ((spec_is_CONSTANT_of_kova(spec0, UNDERSTANDING_TY)) && ([[spec0 == it]] == FALSE))
        coerce_UNDERSTANDING_to_TEXT(spec0);
    if ((spec_is_CONSTANT_of_kova(spec1, UNDERSTANDING_TY)) && ([[spec1 == it]] == FALSE))
        coerce_UNDERSTANDING_to_TEXT(spec1);
    action_name_list *anl = RETRIEVE_FROM_SPEC(spec_found, action_name_list);
    action_name *an = anl_get_singleton_action(anl);
    LOGIF(EXPRESSIONS, "Compiling from action name list:\n$L\n", anl);
    int flag_bits = 0;
    if (is_kova(spec_evaluates_to(spec0), TEXT_TY)) flag_bits += 16;
    if (is_kova(spec_evaluates_to(spec1), TEXT_TY)) flag_bits += 32;
    if (flag_bits > 0) ensure_basic_heap_present();
    if (spec_test_flag(spec_found, ACTION_FOR_OTHER_SPFLAG)) flag_bits += 1;
    WRITE("TryAction(%d, ", flag_bits);
    if (spec2) compile_try_action_parameter(OUT, spec2, kova(OBJECT_TY));
    else WRITE("player");
    WRITE(", ##%s, ", an_get_I6_representation(an));
    if (spec0) compile_try_action_parameter(OUT, spec0, act_get_data_type_of_noun(an));
    else WRITE("0");
    WRITE(", ");
    if (spec1) compile_try_action_parameter(OUT, spec1, act_get_data_type_of_second_noun(an));
    else WRITE("0");
    WRITE(");");
    return;
```

This code is used in §12.

§**19.** Which requires the following. As ever, there have to be hacks to ensure that text as an action parameter is correctly read as parsing grammar rather than text when the action expects that.

```
void compile_try_action_parameter(OUTPUT_STREAM, specification *spec, kind_of_value *required_kov) {
    specification *spec_expected = kov_as_spec(required_kov);
    if (is_kova(required_kov, UNDERSTANDING_TY)) {
        kind_of_value *kov = spec_evaluates_to(spec);
        if ((can_we_cast_kovs(kov, kova(UNDERSTANDING_TY))) ||
            (can_we_cast_kovs(kov, kova(INDEXED_TEXT_TY)))) {
            spec_expected = spec;
        }
    }
    if (typecheck(spec, spec_expected)) spec_compile(OUT, spec);
}
```

Type Checking 7/tc

Purpose

To decide whether a given specification, representing a value or construct found in the source text, can be used in a given context: the possible answers being yes, no, or "possibly, contingent on run-time type checking".

Definitions

```
typedef struct inv_token_problem_token {
    int word_ref1, word_ref2;
    struct specification *as_parsed;
    int already_described;
    MEMORY_MANAGEMENT
} inv_token_problem_token;
```

The structure inv_token_problem_token is private to this section.

---

§**1. The middle level.** Recall that the typechecker is built on three layers. The innermost layer, which is like typechecking in C, tests to see if one kind of value (KOV) can be used in place of another. This is provided by the `can_we_cast_kovs` routine, from "Kinds of Value.w".

The following modest little routine forms the entire middle layer of the typechecker, which expands outwards from single values to think about descriptions. Each of `from_spec` and `to_spec` is either an evaluating specification (an lvalue or rvalue), or a `DESCRIPTION_SPC`.

We find the narrowest possible KOVs for the two specifications and try to compare them. The wrinkle is that if the target `to_spec` is qualified, by adjectives or some proposition, then we can only know at run-time whether a match can be made, so we must return `SOMETIMES_MATCH` instead of `ALWAYS_MATCH`.

```
int can_we_match_value_descriptions(specification *from_spec, specification *to_spec) {
    LOGIF(TYPE_CASTS, "[Can we match from: $S to: $S?]\n", from_spec, to_spec);
    kind_of_value *from_kov = narrowest_KOV_of_value_or_description(from_spec);
    kind_of_value *to_kov = narrowest_KOV_of_value_or_description(to_spec);
    int result = NEVER_MATCH;
    if ((from_kov) && (to_kov)) result = can_we_cast_kovs(from_kov, to_kov);
    else if (to_kov) result = SOMETIMES_MATCH;
    if ((spec_is_qualified_DESCRIPTION(to_spec)) && (result == ALWAYS_MATCH))
        result = SOMETIMES_MATCH;
    switch(result) {
        case ALWAYS_MATCH:    LOGIF(TYPE_CASTS, "[Always]\n"); break;
        case SOMETIMES_MATCH: LOGIF(TYPE_CASTS, "[Sometimes]\n"); break;
        case NEVER_MATCH:     LOGIF(TYPE_CASTS, "[Never]\n"); break;
    }
    return result;
}
```

The function can_we_match_value_descriptions is called from 7/cosp, 11/ap, 12/phtd, 12/cinv and 13/gl.

§**2.** Either the docket or the proposition of a DESCRIPTION_SPC will tell us what it describes. If there's no other indication, it always describes objects.

```
kind_of_value *narrowest_KOV_of_value_or_description(specification *spec) {
    kind_of_value *kov = NULL;
    if (spec_is_evaluating(spec)) kov = spec_evaluates_to(spec);
    else if (species_is(spec, DESCRIPTION_SPC)) {
        if (spec_get_described_kov(spec))
            kov = spec_get_described_kov(spec);
        if (spec_get_described_kind(spec))
            kov = kovko(spec_get_described_kind(spec));
        if (spec_get_proposition(spec))
            kov = prop_describes_KOV(spec_get_proposition(spec));
        if (spec == NULL) kov = kova(OBJECT_TY);
    } else internal_error("tried to narrow KOV for inappropriate specification");
    return kov;
}
```

§**3. The outermost level.** We now have the two inner levels of the type-checker in place, and must write the outermost level: which handles the general case of any specification compared with any other, and which diagnoses failures in detail, producing Problem messages when things go wrong. The main reason that the outermost level is the most complicated is simply that, when checking fails, we need to distinguish between the many reasons why it failed, in order to produce worthwhile Problems. At the inner levels, a fail is a fail.

The outermost level of the typechecker sometimes performs coercion: it will sometimes modify the SP found to amend it in light of the circumstances indicated by the SP expected. It will also remove the one remaining ambiguity in the SP structure: for a phrasal SP with rival invocations, it will decide which invocation(s) will be compiled (or else will issue a Problem if none can be).

Partly because of the need to do this, the type-checker has a top-down approach. It aims to prove that the SP found can match the SP expected, making selections and coercions as needed to do this. For instance, when

> change the score to the score plus 10

is checked to see that it is valid in code, an actual COMMAND_FMY of species TO_PHRASE_SPC is checked against a generic COMMAND_FMY. The typechecker sees at once that this is provably correct, so long as the arguments to the phrase work. There are several valid interpretations of "change ... to ...", and these are all present in the SP found as alternative invocations, so the typechecker tries each in turn, accepting one (or more) if the arguments can be proved to be of the right type. This means proving that argument 0 ("the score") matches a generic NONLOCAL_VARIABLE_SPC and also that argument 1 ("the score plus 10") matches a generic VALUE_FMY. A further rule requires that the kind of value of argument 1 must match the kind of value stored in the variable, here a NUMBER_TY, so we must prove that too. Now "plus" is polymorphic and can produce different kinds of value depending on the kinds of value it acts upon, so again we must check all possible interpretations. But we finally succeed in showing that "score" is a number, "10" is a number, and that "plus" on two numbers gives a number, so we complete the proof and the phrase is accepted.

§**4. Global state information.** Throughout the recursive use of our typechecker, we need some global state data to keep track of two decidedly global side-effects of checking: the issuing of problem messages, and the creation of variables. These irrevocable acts can't be mere flickering possibilities on the stack, like other intermediate results of typechecking a complex expression.

First, we keep track of the problem messages issued, if any. Three grades of problem can appear: "ordinary", "gross" and "grosser than gross". We distinguish these in order to produce a Problem message which reflects the biggest thing wrong, rather than being so esoteric that it misses the main point. Changing a particular error condition from an ordinary to a gross problem, or vice versa, has no effect on the result of `typecheck()`: only on the Problem messages given to the user.

```
define THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM
    no_gross_problems_thrown++;                          problems this gross cannot be suppressed
define THIS_IS_A_GROSS_PROBLEM
    no_gross_problems_thrown++;                          this increments even if the message is suppressed
    if (problem_threshold >= 1) return NEVER_MATCH;      meaning "suppress even gross problems"
define THIS_IS_AN_ORDINARY_PROBLEM
    if (problem_threshold >= 2) return NEVER_MATCH;      meaning "suppress ordinary problems"

int no_gross_problems_thrown = 0;
int problem_count_at_typecheck_start = 0;
```

§**5.**

⟨Zero the counts of problems produced in typechecking 5⟩ ≡

```
    no_gross_problems_thrown = 0;
    problem_count_at_typecheck_start = problem_count;
```

This code is used in §9.

§**6.** And subsequently we detect whether anything untoward has happened:

```
int problems_issued_during_typechecking(void) {
    if (problem_count_at_typecheck_start < problem_count) return TRUE;
    return FALSE;
}
```

§**7.** The other piece of state data is to do with the creation of local variables through the "let" phrase, which happens in the typechecker (since the kind of value for the variable can only be discovered by typechecking). We do not want to allow the recursive typechecker the power to create variables, because it might then use this power in a branch of checking which doesn't work out for some other reason – that would leave us with a bogus variable. Instead, the typechecker records a *request* to make a local variable in the following state variables. If the typechecker succeeds in proving a "let" phrase valid, only then will the variable be created.

```
typedef struct local_variable_request {
    int word_ref1, word_ref2;                                   name of the requested variable
    struct kind_of_value *KOV_from_prototype;                   the KOV it should have
    int depth_made_at;                  the depth of typechecking recursion at which the request was made
    struct specification *local_initial_value;
    struct kind_of_value *recently_discovered_KOV;          used when polymorphism makes this unexpected
} local_variable_request;

local_variable_request requested = { -1, -1, NULL, 0, NULL, NULL };
kind_of_value *KOV_of_recently_created_local = NULL;
```

The structure local_variable_request is private to this section.

§**8.**

⟨Empty any local variable request 8⟩ ≡

```
requested.word_ref1 = -1; requested.word_ref2 = -1;
requested.KOV_from_prototype = NULL;
requested.depth_made_at = 0;
requested.local_initial_value = NULL;
requested.recently_discovered_KOV = NULL;
```

This code is used in §9,97,9,97.

§**9. Capping the recursion.** At this top level, something checks out or it doesn't, so the two top-level routines return `TRUE` or `FALSE`. But beneath this head, the type-checker acts recursively, because the SP structure is itself recursive: some SPs include pointers to further SPs, and these must be type-checked in turn. In that recursion, each call to `typecheck_recursive` returns one of the three values `ALWAYS_MATCH`, `SOMETIMES_MATCH` or `NEVER_MATCH`.

Note that although `typecheck` is not *directly* recursive, it can sometimes be indirectly so, because it calls out to `prop_type_check` at rule (d), which can in turn start fresh rounds of `typecheck`. So we carefully preserve the local variable request on entry and exit – not because `prop_type_check` is likely to make requests (it's in fact not able to, I think), but because its calls to `typecheck` have the side-effect of emptying the request. This was at one time the source of some very subtle bugs occurring only very seldom.

```
int typecheck_without_expectations(specification *found) {
    return typecheck(found, found);
}
int typecheck(specification *found, specification *expected) {
    local_variable_request saved_request = requested;
    ⟨Empty any local variable request 8⟩;
    ⟨Zero the counts of problems produced in typechecking 5⟩;
    int rv = typecheck_recursive(found, expected, 0, 1);
    requested = saved_request;
    if (rv == NEVER_MATCH) return FALSE;
    return TRUE;
}
```

The function typecheck_without_expectations is called from 6/tcpr, 6/cind, 12/cinv, 13/test and 14/i6t.
The function typecheck is called from 7/cmsp, 9/scene, 11/ap and 12/cph.

§**10.** We still cannot quite begin the work, since a wrapper routine provides for careful debug logging of all that goes on. I have spent far too many hours staring at the log of what the typechecker has done. During Inform's infancy, it was not so much that this was the great habitat and breeding ground for bugs; more that those bugs which *were* here were by far the hardest to root out. So careful logging on demand is vital.

```
define LOG_STAGE_LEFT(stage)
    LOGIF(INVOCATIONS, "[%d%s] %s $S",
        unique_TR_call_identifier,
        (problem_threshold == 0)?"":
            ((problem_threshold == 1)?"-quiet":"-silent"), stage, found);
define LOG_STAGE(stage)
    { LOG_STAGE_LEFT(stage); LOGIF(INVOCATIONS, "\n"); }

int unique_TR_call_identifier = 0, TR_call_counter = 0;
int typecheck_recursive(specification *found, specification *expected,
    int problem_threshold, int depth) {
```

```
    int outer_id = unique_TR_call_identifier;
    unique_TR_call_identifier = TR_call_counter++;
    STREAM_INDENT(dl);
    LOG_STAGE_LEFT("try"); LOGIF(INVOCATIONS, " --?--> $S\n", expected);
    STREAM_INDENT(dl);
    int return_value = typecheck_recursive_inner(found, expected, problem_threshold, depth);
    STREAM_OUTDENT(dl);
    switch(return_value) {
        case ALWAYS_MATCH:    LOG_STAGE("always match"); break;
        case SOMETIMES_MATCH: LOG_STAGE("sometimes match"); break;
        case NEVER_MATCH:     LOG_STAGE("never match"); break;
        default: internal_error("impossible verdict from recursive typechecker");
    }
    STREAM_OUTDENT(dl);
    unique_TR_call_identifier = outer_id;
    return return_value;
}
```

§**11.** We first do a little fussing over `found` and `expected`.

```
int typecheck_recursive_inner(specification *found, specification *expected,
    int problem_threshold, int depth) {
    if ((expected) && (!(spec_is_UNKNOWN(expected))))
        type_ID_observe(expected, TYPE_EXPECTED_SPCONTEXT);
    if ((found) && (!(spec_is_UNKNOWN(found))))
        type_ID_observe(found, TYPE_FOUND_SPCONTEXT);
    if (spec_is_generic_CONSTANT(found))
        ⟨Coerce a found generic constant to a description 12⟩;
    if (spec_is_generic(found)) internal_error("type-check on a generic found specification");
    ⟨Perform the type-checking algorithm 13⟩;
}
```

§**12.** Inside the belly of the typechecker, `found` has to be an actual specification, because it's something which may be compiled some day. The only way we can see a generic `found` is as a result of an ambiguity in English. Consider:

> Colour is a kind of value.
>
> [1] Red is a colour.
>
> [2] let N be the number of colours;

In excerpt [1], "colour" is generic and will never be compiled as a value, but in [2] "colours" is something actual – it has to be compiled to a routine enumerating colours, which can be passed to the "number of ..." phrase. But both usages parse to generic `CONSTANT_SPC` specifications.

It's only when we typecheck that we realise we must mean this as an actual description, and we perform a coercion to turn the specification from a generic `CONSTANT_SPC` to an actual `DESCRIPTION_SPC`.

As can be seen, we can get rid of some easy typechecking cases straight away: a generic K_1 value matches a generic K_2 value if $K_1 \subseteq K_2$. In particular this ensures that a generic K_1 matches itself. But even if there's a match, the specification is still coerced. So even in this one permitted case when `found` is allowed into the typechecker while generic, it can't leave that way.

⟨Coerce a found generic constant to a description 12⟩ ≡

```
int x = NEVER_MATCH;
if (spec_is_generic_CONSTANT(expected))
    x = can_we_cast_kovs(spec_get_kind_of_value(found),
            spec_get_kind_of_value(expected));
coerce_generic_CONSTANT_to_DESCRIPTION(found);
if (x != NEVER_MATCH) return x;
```

This code is used in §11.

§**13.** From here on `found` is certainly an actual SP, and `expected` can be either actual or generic. It's time to perform some checking.

The best way to think about this algorithm is that it nearly does something simple: it compares the species of `found` and `expected` to see if they match or not. This is called the Main Rule, and even though it is partially buried under a great heap of exceptions and finicky special cases, it remains most of the story. Here is a less sketchy account:

(a) Handle the creation of new local variable names, using either text with no known meaning, or in some cases allowing the overloading of an existing meaning. Reject unknown meanings found in all other cases.

(b) Handle the case where a specific constant value expected.

(c) Make coercions, 1: expand bare property names into what they seem to be intended as properties of. For instance, "carrying capacity" might be interpreted as "carrying capacity of the item discussed". Reject bad property values.

(d) Make coercions, 2: typecheck any proposition attached to the SP found, and coerce to "now" rather than "test" form if that's expected.

(e) Make coercions, 3: miscellaneous other coercions to bring the SP found into line with what was expected.

(f) To match a generic constant value of KOV K, the SP found has to evaluate to a KOV which implicitly casts to K. To match a description, the SP found has to either specify an object which satisfies it, or has to be a description provably contained within it. In all other cases, the SP found matches if and only if it has the same species as the SP expected.

(g) Recurse downwards to typecheck any arguments.

(h) Make sure that structural commands are used in the right places: for instance, cases appear inside switches, and so on.

(i) Check through the list of invocations, if there is one, and select which possibilities remain for consideration at run-time. (Usually in fact there is just one possibility.)

⟨Perform the type-checking algorithm 13⟩ ≡

```
int best_result = ALWAYS_MATCH;      drops to SOMETIMES_MATCH if a need for run-time checking is realised
⟨Step (a) Deal with the UNKNOWN 14⟩;
⟨Step (b) Deal with expected actual CONSTANT types 26⟩;
⟨Step (c) Deal with bare property names 29⟩;
⟨Step (d) Deal with any attached proposition 34⟩;
⟨Step (e) Apply miscellaneous other coercions 38⟩;
⟨Step (f) The Main Rule of Type-Checking 45⟩;
if (spec_get_argc(found) > 0) ⟨Step (g) Recurse down to check arguments 53⟩;
if (family_is(found, COMMAND_FMY)) ⟨Step (h) Police the global structure of phrase bodies 62⟩;
if (spec_has_invocation_list(found)) ⟨Step (i) Typecheck the invocations, choosing among them 67⟩;
return best_result;
```

This code is used in §11.

§14. Rule (a). It might seem rather odd that the typechecker should ever have to deal with `found` being unknown text. Surely that's a sign that the parsing went wrong, so how did things get to this stage?

In a C-like language, where variables are predeclared, that would be true. But in Inform, a phrase like:

```
let the monster be a random pterodactyl;
```

can be valid even where "the monster" is text not known to the S-parser as yet – indeed, that's how local variables are made. It's the typechecker which sorts this out, because only the typechecker can decide which of the subtly different forms of "let" is being used. So, in short, we do need to cope with `found` containing an `UNKNOWN` specification. We get it out of the way first.

⟨Step (a) Deal with the UNKNOWN 14⟩ ≡
```
⟨Step (a.1) Deal with "kind of word value" and "kind of problem value" 15⟩;
⟨Step (a.2) Deal with text where a nonexisting variable name is expected 17⟩;
⟨Step (a.3) Let all other UNKNOWN text lead to a problem message 19⟩;
```

This code is used in §13.

§15. Rule (a.1) is a delicate manoeuvre, but luckily it takes action only very rarely and in very specific circumstances. The data type IDs `KIND_OF_WORD_VALUE_TY` and `KIND_OF_POINTER_VALUE_TY` are the way we match phrase definitions like

```
let (name - nonexisting variable) be (type - kind of word value);
```

where the "type" parameter has to be the name of any KOV which can be stored in a single word (rather than a pointer to data on the heap) – thus, we match [1] and [2] but not [3], [4] or [5] from:

```
[1] let X be a number;
[2] let X be a vehicle;
[3] let X be indexed text;
[4] let X be 21;
[5] let X be {1, 2, 3};
```

`KIND_OF_POINTER_VALUE_TY` represents "kind of pointer value" and would contrariwise allow only [3].

What all of this has to do with being `UNKNOWN` is that text parsed in the expectation of a value will usually not recognise something like "a list of numbers", so that would be here as `UNKNOWN`. We take the otherwise unheard-of measure of reparsing the text, but we only impose the result on `found` if the match can definitely be made successfully.

⟨Step (a.1) Deal with "kind of word value" and "kind of problem value" 15⟩ ≡
```
LOG_STAGE("(a.1)");
int pointer_status = NOT_APPLICABLE;

        "this is a phrase which I don't recognise",
        "possibly because it is one you meant to define but never got round "
        "to, or because the wording is wrong (see the Phrasebook section of "
        "the Index to check). Alternatively, it may be that the text "
        "immediately previous to this was a definition whose ending, normally "
        "a full stop, is missing?");
    return NEVER_MATCH;
```

This code is used in §19.

§**22.**

⟨Unknown found text occurs as a text substitution 22⟩ ≡

```
if [[found == COMMA ...]] {
    handmade_problem(_P_(C7SayComma));
    issue_problem_segment(
        "In the line %1, I was expecting that '%2' would be something to "
        "'say', but unexpectedly it began with a comma. The usual form is "
        "just 'say \"text\"', perhaps with some substitutions in square "
        "brackets within the quoted text, but no commas.");
    issue_problem_end();
} else if [[found == unicode ...]] {
    handmade_problem(_P_(C7SayUnicode));
    issue_problem_segment(
        "In the line %1, I was expecting that '%2' would be something to "
        "'say', but it didn't look like any form of 'say' that I know. "
        "So I tried to read '%2' as a Unicode character, which seemed "
        "likely because of the word 'unicode', but that didn't work either. "
        "%PUnicode characters can be written either using their decimal "
        "numbers - for instance, 'Unicode 2041' - or with their standard "
        "names - 'Unicode Latin small ligature oe'. For efficiency reasons "
        "these names are only available if you ask for them; to make them "
        "available, you need to 'Include Unicode Character Names by Graham "
        "Nelson' or, if you really need more, 'Include Unicode Full "
        "Character Names by Graham Nelson'.");
    issue_problem_end();
} else {
    if [[found == ... condition]] handmade_problem(_P_(C7SayUnknownCondition));
    else handmade_problem(_P_(C7SayUnknown));
    issue_problem_segment(
        "In the line %1, I was expecting that '%2' would be something to "
        "'say', but it didn't look like any form of 'say' that I know. So "
        "I tried to read '%2' as a value of some kind (because it's legal "
        "to say values), but couldn't make sense of it that way either. "
        "%PSometimes this happens because punctuation has gone wrong - "
        "for instance, if you've omitted a semicolon or full stop at the "
        "end of the 'say' phrase.");
    if [[found == ... condition]] {
        issue_problem_segment(
            "%PNames which end in 'condition' often represent the current "
            "state of something which can be in any one of three or more "
            "states. This will only be the case if you have explicitly said "
            "so, with a line like 'The rocket is either dry, fuelled or launched.' - "
            "in which case the value 'rocket condition' will always be one "
            "of 'dry', 'fuelled' or 'launched'. Note that all of this only "
            "applies to a list of three or more possibilities - a thing can "
            "have any number of either/or properties. For instance, a "
            "container is open or closed, but it also transparent or opaque. "
            "Neither of these counts as its 'condition'.");
    }
    issue_problem_end();
}
```

This code is used in §19.

§**23.** It's a bit unenlightening when an entire condition is rejected as unknown if, in fact, only one of perhaps many clauses is broken. We therefore produce quite an elaborate problem message which goes through the clauses, summing up their status in turn:

⟨Issue a problem message for a compound condition which has gone bad 23⟩ ≡

```
handmade_problem(_P_(C7CompoundConditionFailed));
issue_problem_segment(
    "In the sentence %1, I was expecting that '%2' would be a condition. "
    "It didn't make sense as one long phrase, but because it was divided up by "
    "'and'/'or', I tried breaking it down into smaller conditions, but "
    "that didn't work either. ");
if (issue_condition_error_bit(found->word_ref1, found->word_ref2))
    issue_problem_segment(
        "but that combination of conditions isn't allowed to be joined "
        "together with 'and' or 'or', because that would just be too confusing. "
        "%PFor example, 'if the player is carrying a container or a "
        "supporter' has an obvious meaning in English, but Inform reads "
        "it as two different conditions glued together: 'if the player is "
        "carrying a container', and also 'a supporter'. The meaning of "
        "the first is obvious. The second part is true if the current "
        "item under discussion is a supporter - for instance, the noun of "
        "the current action, or the item to which a definition applies. "
        "Both of these conditions are useful in different circumstances, "
        "but combining them in one condition like this makes a very "
        "misleading line of text. So Inform disallows it.");
else
    issue_problem_segment(
        "so I ran out of ideas.");
issue_problem_end();
```

This code is used in §19.

§**24.** These are cases where the wording used in the source text suggests some common misunderstanding.

⟨Issue a problem message for miscellaneous suspicious wordings 24⟩ ≡

```
int w1 = found->word_ref1 - 2, w2 = found->word_ref2;
if [[w1, w2 == number of turns]] {
    handmade_problem(_P_(C7NumberOfTurns));
    ⟨Issue the generic unknown wording message 25⟩;
    issue_problem_segment(
        "%PGenerally speaking, 'number of ...' constructions are only "
        "allowed when counting up rooms or things: if by 'number of "
        "turns' you meant the number of turns of play to date, try "
        "'turn count' instead.");
    issue_problem_end();
} else if [[found == ... is/are out of play]] {
    handmade_problem(_P_(C7OutOfPlay));
    ⟨Issue the generic unknown wording message 25⟩;
    issue_problem_segment(
        "%PPeople sometimes say that things or people removed from all "
        "rooms are 'out of play', but Inform uses the adjective "
```

```
        "'off-stage' - for instance, 'if the ball is off-stage'. "
        "If you would like 'out of play' to work, you could always "
        "write 'Definition: A thing is out of play if it is off-stage.' "
        "Then the two would be equivalent.");
    issue_problem_end();
} else if ((is_kova(spec_get_kind_of_value(expected), USEOPTION_TY)) &&

    ⟨Issue the generic unknown wording message 25⟩;
    issue_problem_segment(
        "%PNames which end in 'condition' often represent the current "
        "state of something which can be in any one of three or more "
        "states. Names like this only work if you've declared them, with "
        "a line like 'The rocket is either dry, fuelled or launched.' - "
        "in which case the value 'rocket condition' will always be one "
        "of 'dry', 'fuelled' or 'launched'. Maybe you forgot to declare "
        "something like this, or mis-spelled the name of the owner?");
    issue_problem_end();
} else if [[found == OPENBRACE ... CLOSEBRACE]] {
    handmade_problem(_P_(C7BadConstantList));
    ⟨Issue the generic unknown wording message 25⟩;
```

```
        issue_problem_segment(
            "%PNote that lists have to be written with spaces before commas, "
            "so I like '{2, 4}' but not '{2,4}', for instance.");
        issue_problem_end();
    } else {
        handmade_problem(_P_(C7Unknown));
        ⟨Issue the generic unknown wording message 25⟩;
        issue_problem_end();
    }
```

This code is used in §19.

§**25.**

⟨Issue the generic unknown wording message 25⟩ ≡

```
    issue_problem_segment(
        "In the sentence %1, I was expecting to read %3, but instead found some "
        "text that I couldn't understand - '%2'. ");
```

This code is used in §24.

§**26. Rule (b).** This is something else that wouldn't appear in a typical compiler's typechecker. Here we are dealing with a phrase specification such as:

To attract (N - 10) things: ...

where the "N" argument will be accepted if and only if it's the value 10. The fact that Inform allows this is further evidence of the slippery way that natural language doesn't distinguish values from types; early designs of Inform didn't allow it, but many people reported this as a bug.

⟨Step (b) Deal with expected actual CONSTANT types 26⟩ ≡

```
    LOG_STAGE("(b)");
    if ((spec_is_evaluating(found)) && (spec_is_actual_CONSTANT(expected)) &&
        (found != expected)) {
        kind_of_value *kov_found = spec_evaluates_to(found);
        kind_of_value *kov_expected = spec_get_kind_of_value(expected);
        int failed = FALSE;
        if (spec_is_actual_CONSTANT(found)) {
            if (!(spec_compare_CONSTANT(found, expected))) failed = TRUE;
        } else if (is_kova(kov_found, ANY_VALUE_TY)) {
            best_result = SOMETIMES_MATCH;
            LOGIF(INVOCATIONS, "dropping to sometimes level for polymorphism\n");       see
below
        } else if (can_we_cast_kovs(kov_found, kov_expected) != NEVER_MATCH) {
            best_result = SOMETIMES_MATCH;
            LOGIF(INVOCATIONS, "dropping to sometimes level for value matching\n");
        } else failed = TRUE;
        if (failed) ⟨Fail typechecking rule (b) 28⟩;
    }
```

This code is used in §13.

§**27.** To explain the cryptic use of `ANY_VALUE_TY`:

When `found` appears to have KOV "value" – the broadest KOV that could possibly exist – what this usually means is that the KOV isn't known yet. That will be the case if `found` invokes a polymorphic arithmetic phrase, so that only typechecking (which isn't finished yet) will tell its KOV. For instance, rule (b) applied to `found` being "10km plus 20km" in the following:

```
attract 10km plus 20km things;
```

...will result in `best_result` being lowered to `SOMETIMES_MATCH`. This does *not* have the effect of accepting `found` – which is good, because it needs to be rejected – but only of saying "If we ever accept this, it will have to be subject to run-time checking."

§**28.** We fail `found` in only two circumstances: (i) where we can demonstrate that `found` is a different constant from `expected`, or (ii) where we can demonstrate that `found` and `expected` have incomparable KOVs.

⟨Fail typechecking rule (b) 28⟩ ≡

```
LOGIF(INVOCATIONS, "(b) on $S rejected: found $u, expected $u\n",
    found, kov_found, kov_expected);
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
quote_spec(3, found);
quote_spec(4, expected);
handmade_problem(_P_(C7NotExactValueWanted));
issue_problem_segment(
    "In the sentence %1, I was expecting that '%2' would be the specific "
    "value '%4'.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §26.

§**29. Rule (c).** This is all concerned with a shorthand far more convenient to an Inform author than it is to us – where a property's name is used without any indication of its owner.

⟨Step (c) Deal with bare property names 29⟩ ≡

```
LOG_STAGE("(c)");
if (spec_is_CONSTANT_of_kova(found, PROPERTY_TY)) {
    ⟨Step (c.1) If a bare property name is used where we expect one, accept it 30⟩;
    ⟨Step (c.2) If a bare property name is used where we expect a property value, coerce it 31⟩;
    ⟨Step (c.3) If a bare property name is used where we expect a value, coerce it if the KOVs allow 32⟩;
}
```

This code is used in §13.

§**30.** Step (c.1) is needed only to avoid rejecting this case wrongly at (c.3).

⟨Step (c.1) If a bare property name is used where we expect one, accept it 30⟩ ≡

```
LOG_STAGE("(c.1)");
if (spec_is_generic_CONSTANT_of_kova(expected, PROPERTY_TY)) return ALWAYS_MATCH;
```

This code is used in §29.

§**31.** Sometimes we definitely want a property value, for instance in a phrase explicitly set up to manipulate those.

⟨Step (c.2) If a bare property name is used where we expect a property value, coerce it 31⟩ ≡

```
LOG_STAGE("(c.2)");
if (spec_get_storage_form(expected) == PROPERTY_VALUE_SPC) {
    property_name *prn = spec_get_property_name_if_any(found);
    if (prn_is_value_property(prn)) {
        ⟨Coerce into a property of the "self" object 33⟩;
        return ALWAYS_MATCH;
    }
}
```

This code is used in §29.

§**32.** But more often we want a value which just happens in this case to come from a property. For instance, in a text routine printing a description like "The cedarwood box could hold [carrying capacity in words] item[s].", we want "carrying capacity" to be a number value, and we treat it as if it read "carrying capacity of the cedarwood box".

⟨Step (c.3) If a bare property name is used where we expect a value, coerce it if the KOVs allow 32⟩ ≡

```
LOG_STAGE("(c.3)");
if (spec_is_generic_CONSTANT(expected)) {
    property_name *prn = spec_get_property_name_if_any(found);
    if (prn_is_value_property(prn)) {
        kind_of_value *kov_if_coerced = prn_get_kind_of_value(prn);
        kind_of_value *kov_expected = spec_get_kind_of_value(expected);
        int verdict = can_we_cast_kovs(kov_if_coerced, kov_expected);
        if (verdict != NEVER_MATCH) {
            ⟨Coerce into a property of the "self" object 33⟩;
        } else {
            LOGIF(INVOCATIONS, "(c.3) declining to cast into property value form\n");
        }
        return verdict;
    }
}
```

This code is used in §29.

§**33.** The tricky part is working out what the implicitly meant object is, a classic donkey anaphora-style problem in linguistics. We don't even begin to solve that here: indeed the decision is taken rather indirectly, because we simply compile code which uses Inform 6's `self` variable to refer to the owner. The I6 library and our own run-time code conspire to ensure that `self` is always equal to something sensible.

⟨Coerce into a property of the "self" object 33⟩ ≡

```
specification *become = new_PROPERTY_VALUE_spec(spec_copy(found), new_self_object_constant());
*found = *become;
spec_set_flag(found, COERCED_SPFLAG);
LOGIF(INVOCATIONS, "(c) coercing PROPERTY to PROPERTY VALUE: $S\n", found);
```

This code is used in §31,32,31,32,31,32.

§34. Rule (d).

⟨Step (d) Deal with any attached proposition 34⟩ ≡
```
⟨Step (d.1) Typecheck any proposition found 35⟩;
⟨Step (d.2) Coerce tested proposition to NOW form 36⟩;
```

This code is used in §13.

§35. An unchecked SP can contain a proposition which, though valid as a predicate calculus sentence, makes no sense for type reasons: for instance, "the Orange Room is 10" compiles to a valid sentence but one in which the binary predicate for equality is applied to incomparable SPs. To typecheck, we must prove that any proposition needed is valid on these grounds, and we delegate that to "Type Check Propositions.w".

⟨Step (d.1) Typecheck any proposition found 35⟩ ≡
```
LOG_STAGE("(d.1)");
char *desired_to = NULL;
if (species_is(found, TEST_PROPOSITION_SPC)) desired_to = "be a condition";
if (species_is(found, DESCRIPTION_SPC)) desired_to = "be a description";
if (desired_to) {
    if (prop_type_check(spec_get_proposition(found), tc_no_problem_reporting())
        == NEVER_MATCH) {
        LOGIF(INVOCATIONS, "(d.1) on $S failed proposition type-checking\n", found);
        THIS_IS_A_GROSS_PROBLEM;
        prop_type_check(spec_get_proposition(found),
            tc_problem_reporting(found->word_ref1, found->word_ref2, desired_to));
        return NEVER_MATCH;
    }
}
```

This code is used in §34.

§36. The text in a phrase such as

now the cat is on the mat;

is parsed as a condition, which means `found` for the single argument to "now" will belong to the `CONDITION_FMY` family. But the only valid sort of condition here is a `TEST_PROPOSITION_SPC`, such as "the cat is on the mat". We want to reject other sorts of condition, and we find it convenient to coerce even a test into `NOW_PROPOSITION_SPC` form, to mark it out.

⟨Step (d.2) Coerce tested proposition to NOW form 36⟩ ≡
```
LOG_STAGE("(d.2)");
if (species_is(expected, NOW_PROPOSITION_SPC)) {
    if (species_is(found, TEST_PROPOSITION_SPC))
        coerce_TEST_PROPOSITION_to_NOW_PROPOSITION(found);
    else if (family_is(found, CONDITION_FMY))
        ⟨Issue a problem message for the wrong sort of condition in a "now" 37⟩;
}
```

This code is used in §34.

§**37.** Another deluxe problem message.

⟨Issue a problem message for the wrong sort of condition in a "now" 37⟩ ≡

```
THIS_IS_A_GROSS_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
if (species_is(found, PHRASE_TO_DECIDE_IF_SPC)) {
    handmade_problem(_P_(C7BadNow1));
    issue_problem_segment(
        "You wrote %1, but although '%2' is a condition which it is legal "
        "to test with 'if', 'when', and so forth, it is not something I "
        "can arrange to happen on request. Whether it is true or not "
        "depends on current circumstances: so to make it true, you will "
        "need to adjust those circumstances.");
    issue_problem_end();
} else if (species_is(found, LOGICAL_AND_SPC)) {
    handmade_problem(_P_(C7BadNow2));
    issue_problem_segment(
        "You wrote %1, but 'now' does not work with the condition '%2' "
        "because it can only make one wish come true at a time: so it "
        "doesn't like the 'and'. Try rewriting as two 'now's in a row?");
    issue_problem_end();
} else {
    handmade_problem(_P_(C7BadNow3));
    issue_problem_segment(
        "You wrote %1, but '%2' isn't the sort of condition which can be "
        "made to be true, in the way that 'the box is on the table' can be "
        "made true with a straightforward movement of one object (the ball).");
    issue_problem_end();
}
return NEVER_MATCH;
```

This code is used in §36.

§**38. Rule (e).** Something of a grab-bag, this one. What these three situations have in common is that all use the typechecker to clarify ambiguities in syntax.

⟨Step (e) Apply miscellaneous other coercions 38⟩ ≡

```
⟨Step (e.1) Coerce TEST ACTION to TRY ACTION 39⟩;
⟨Step (e.2) Coerce constant TEXT and TEXT ROUTINE to UNDERSTANDING 40⟩;
⟨Step (e.3) Coerce a description to a value, if we expect a noun-like description 41⟩;
⟨Step (e.4) Reject plausible but wrong uses due to use of inline-only types in phrases 44⟩;
```

This code is used in §13.

§39. An action pattern can be an action if specific enough, and this is crucial: it enables phrases such as "try taking the box" to work. When such phrases are type-checked, they expect the argument to be an `TRY_ACTION_SPC`, which is a specific action: but what they find is an `TEST_ACTION_SPC`, which may be a vague pattern-matching definition applying to many possible actions.

⟨Step (e.1) Coerce TEST ACTION to TRY ACTION 39⟩ ≡

```
LOG_STAGE("(e.1)");
if ((species_is(found, TEST_ACTION_SPC)) && (species_is(expected, TRY_ACTION_SPC))) {
    action_pattern *ap = RETRIEVE_FROM_SPEC(found, action_pattern);
    if (ap_is_unspecific(ap)) {
        THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
        quote_source(1, current_sentence);
        quote_words(2, found->word_ref1, found->word_ref2);
        handmade_problem(_P_(C7ActionNotSpecific));
        issue_problem_segment(
            "You wrote %1, but '%2' is too vague to describe a specific action. "
            "%PIt has to be an exact instruction about what is being done, and "
            "to what. For instance, 'taking the box' is fine, but 'dropping or "
            "taking something openable' is not.");
        issue_problem_end();
        return NEVER_MATCH;
    }
    if (ap_is_overspecific(ap)) {
        THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
        quote_source(1, current_sentence);
        quote_words(2, found->word_ref1, found->word_ref2);
        handmade_problem(_P_(C7ActionTooSpecific));
        issue_problem_segment(
            "You wrote %1, but '%2' imposes too many restrictions on the "
            "action to be carried out, by saying something about the "
            "circumstances which you can't guarantee will be true. "
            "%PSometimes this problem appears because I've misread text like "
            "'in ...' as a clause saying that the action takes place in a "
            "particular room, when in fact it was part of the name of one of "
            "the items involved. If that's the problem, try using 'let' to "
            "create a simpler name for it, and then rewrite the 'try' to use "
            "that simpler name - the ambiguity should then vanish.");
        issue_problem_end();
        return NEVER_MATCH;
    }
    coerce_TEST_ACTION_to_TRY_ACTION_by_ap(found, ap);
    return ALWAYS_MATCH;
}
```

This code is used in §38.

§**40.** The following applies only to literal text in double-quotes, which might or might not include text substitutions in square brackets: if we check it against `UNDERSTANDING_TY`, then we are trying to interpret it as a grammar to parse rather than text to print. We need to coerce since these have very different representations at run-time.

⟨Step (e.2) Coerce constant TEXT and TEXT ROUTINE to UNDERSTANDING 40⟩ ≡

```
LOG_STAGE("(e.2)");
if (((spec_is_CONSTANT_of_kova(found, TEXT_TY)) ||
    (spec_is_CONSTANT_of_kova(found, TEXT_ROUTINE_TY))) &&
    (spec_is_CONSTANT_of_kova(expected, UNDERSTANDING_TY))) {
    spec_set_flag(found, COERCED_SPFLAG);
    spec_set_kind_of_value(found, kova(UNDERSTANDING_TY));
}
```

This code is used in §38.

§**41.** Another ambiguity is that the text "women who are in lighted rooms" in:

```
let N be the number of women who are in lighted rooms;
```

...is parsed as a `DESCRIPTION_SPC`, in the `CONDITION_FMY` family. But in fact it's a noun here – it has to be a value, in fact, which can go into the "number of..." phrase as an argument. We make this happen by coercing it to a constant value.

We distinguish between two forms of noun-like description:

```
[1] to scrutinise (D - description);

[2] to scrutinise (V - value description);
```

which coerce to `kova(OBJECT_DESCRIPTION_TY)` and `kova(VALUE_DESCRIPTION_TY)` respectively. This is done because the implementation of "scrutinise" generally has to be very different when ranging over values than when ranging over objects, so we can give two different definitions and the type-checker will sort out which is needed – "scrutinise open containers" will match [1], but "scrutinise even numbers" will match [2].

⟨Step (e.3) Coerce a description to a value, if we expect a noun-like description 41⟩ ≡

```
LOG_STAGE("(e.3)");
int D_not_V = NOT_APPLICABLE;
if (spec_is_CONSTANT_of_kova(expected, OBJECT_DESCRIPTION_TY)) D_not_V = TRUE;
else if (spec_is_CONSTANT_of_kova(expected, VALUE_DESCRIPTION_TY)) D_not_V = FALSE;
if ((D_not_V != NOT_APPLICABLE) && (species_is(found, DESCRIPTION_SPC))) {
    int describes_objects = TRUE;
    kind_of_value *kov = spec_get_described_kov(found);
    if ((kov) && (can_we_cast_kovs(kov, kova(OBJECT_TY)) != ALWAYS_MATCH))
        describes_objects = FALSE;
    LOGIF(INVOCATIONS, "(e.3) D_not_V is %d, describes_objects is %d\n",
        D_not_V, describes_objects);
    ⟨Throw out the wrong sort of description with a seldom-seen problem message 42⟩;
    if (coerce_DESCRIPTION_to_VALUE(found, describes_objects) == FALSE)
        ⟨Issue a problem message for a malformed proposition in the description 43⟩;
    return ALWAYS_MATCH;
}
```

This code is used in §38.

§**42.** The following message is seldom seen since most phrases using descriptions are set up with two parallel versions. As every description matches exactly one of these, there won't be a problem. But just in case the user has intentionally defined a phrase for only one case:

⟨Throw out the wrong sort of description with a seldom-seen problem message 42⟩ ≡

```
if (D_not_V != describes_objects) {
    THIS_IS_AN_ORDINARY_PROBLEM;
    quote_source(1, current_sentence);
    quote_words(2, found->word_ref1, found->word_ref2);
    if (D_not_V == TRUE) {
        handmade_problem(_P_(C7WrongDescriptionAsNoun1));
        issue_problem_segment(
            "In the line %1, the text '%2' is given where a description of "
            "a collection of objects was required. For instance, 'rooms which "
            "contain something' would be fine, or 'closed containers' - but "
            "not a description of values which aren't objects, like 'all "
            "scenes' or 'even numbers'.");
        issue_problem_end();
    } else {
        handmade_problem(_P_(C7WrongDescriptionAsNoun2));
        issue_problem_segment(
            "In the line %1, the text '%2' is given where a description of "
            "values was required. For instance, 'recurring scenes' or 'even "
            "numbers' would be fine, but not something like 'closed containers' "
            "or 'things which are in lighted rooms' - those describe objects.");
        issue_problem_end();
    }
    return NEVER_MATCH;
}
```

This code is used in §41.

§**43.** I can't see an easy proof that this can never occur, but nor can I make it happen. The problem message is just in case someone finds a way. It appears if the description has a proposition with other than one free variable, once any universal quantifier ("all", etc.) is removed.

⟨Issue a problem message for a malformed proposition in the description 43⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
handmade_problem(_P_(BelievedImpossible));
issue_problem_segment(
    "In the line %1, the text '%2' is given where a description of a collection "
    "of things or values was required. For instance, 'rooms which contain "
    "something', or 'closed containers' - note that there is no need to say "
    "'all' or 'every' in this context, as that is understood already.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §41.

§**44.** It might look as if this ought to be checked when phrase definitions are made; the trouble is, "action", "condition" and so on *are* valid in phrase definitions, but only in inline-defined ones. We don't want to get into all that here, because the message is aimed more at Inform novices who have made an understandable confusion.

⟨Step (e.4) Reject plausible but wrong uses due to use of inline-only types in phrases 44⟩ ≡

```
if (family_is(found, STORAGE_FMY)) {
    kind_of_value *kov = spec_evaluates_to(found);
    if (kov == NULL) {
        THIS_IS_AN_ORDINARY_PROBLEM;
        quote_source(1, current_sentence);
        quote_words(2, found->word_ref1, found->word_ref2);
        handmade_problem(_P_(C7PhraseParameterInlineOnly));
        issue_problem_segment(
            "In the line %1, '%2' ought to be a value, but isn't - there must be "
            "something fishy about the way it was created. %P"
            "Usually this happens because it is one of the named items in "
            "a phrase definition, but stood for a chunk of text which can't "
            "be a value - for instance, 'To marvel at (feat - an action)' "
            "doesn't make 'feat' a value. (Calling it a 'stored action' "
            "would have been fine; and similarly, if you want something "
            "which is either true or false, use 'truth state' not 'condition'.)");
        issue_problem_end();
        return NEVER_MATCH;
    }
}
```

This code is used in §38.

§**45. Rule (f).** The "main rule" is, as we shall see, that `found` should have the same species as `expected`, or if `expected` give no species then at least it should have the same family. The two exceptional cases are when `expected` is a description such as "an even number", or the name of a kind of value such as "a scene", in which case we allow `found` if it's a value which meets these requirements.

⟨Step (f) The Main Rule of Type-Checking 45⟩ ≡

```
int exceptional_case = FALSE;
⟨Step (f.1) Exception: when expecting a DESCRIPTION 46⟩;
⟨Step (f.2) Exception: when expecting a generic or actual CONSTANT 49⟩;
if (exceptional_case == FALSE) ⟨Step (f.3) Main rule 51⟩;
```

This code is used in §13.

§**46.** Suppose we are matching the parameter of a phrase like this:

To inspect (D - an open door): ...

Then we might have `found` set to a constant value – "the Marble Portal", say – and `expected` would be a `DESCRIPTION_SPC` for open doors.

What we must do is to see whether `found` is a value that satisfies the description. Any match will be at best at the "sometimes" level, since by definition a `DESCRIPTION_SPC` is something we can't always prove that a value meets until run-time.

⟨Step (f.1) Exception: when expecting a DESCRIPTION 46⟩ ≡

```
LOG_STAGE("(f.1)");
if ((species_is(expected, DESCRIPTION_SPC)) &&
    (spec_is_actual(expected)) &&
    (found != expected)) {
    if ((spec_is_nothing_object_constant(found)) &&
        (spec_get_described_kind(expected)))
        ⟨Disallow "nothing" as a match for a description requiring a kind of object 47⟩;
    int rv = NEVER_MATCH;
    if (!(species_is(found, DESCRIPTION_SPC)))
        rv = can_we_match_value_descriptions(found, expected);
    if (rv == NEVER_MATCH)
        ⟨Fail on the grounds that the description has not been met 48⟩;
    best_result = rv;
    if (rv == SOMETIMES_MATCH)
        LOGIF(INVOCATIONS, "dropping to sometimes level for description\n");
    exceptional_case = TRUE;
}
```

This code is used in §45.

§**47.** "You can't have/ Something for nothing," as Canadian power-trio *Rush* tell us with the air of having just made a great discovery; well, you can't have "nothing" for something, either –

⟨Disallow "nothing" as a match for a description requiring a kind of object 47⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
quote_object(3, spec_get_described_kind(expected));
handmade_problem(_P_(C7NothingForSomething));
issue_problem_segment(
    "You wrote %1, but '%2' is literally no thing, and it consequently does "
    "not count as %3.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §46.

§**48.** More orthodox failures:

⟨Fail on the grounds that the description has not been met 48⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
if (spec_get_described_kind(expected)) quote_object(3, spec_get_described_kind(expected));
else quote_words(3, expected->word_ref1, expected->word_ref2);
if (species_is(found, DESCRIPTION_SPC)) {
    LOG("Description found: $S\nDescription expected: $S\n", found, expected);
    if (spec_get_proposition(found)) {
        handmade_problem(_P_(C7GenericDescription));
        issue_problem_segment(
            "In the line %1, I read '%2' where I was expecting to find a "
            "(single) specific example of '%3'. Although what you wrote did "
            "make sense as a description, it could refer to many different "
            "values or to none, so it wasn't specific enough.");
        issue_problem_end();
    } else {
        handmade_problem(_P_(C7NotSpecificDescription2));
        issue_problem_segment(
            "In the line %1, I read '%2' where I was expecting to find a "
            "(single) specific example of '%3'.");
        issue_problem_end();
    }
} else {
    if (spec_is_actual_CONSTANT_of_kova(found, OBJECT_TY))
        quote_object(4, OBJECT_spec_to_world_object(found)->kind);
    else
        quote_spec(4, found);
    handmade_problem(_P_(C7WrongKind));
    issue_problem_segment(
        "You wrote %1, but '%2' has the wrong kind of value to go there: %4 "
        "instead of %3.");
    issue_problem_end();
}
return NEVER_MATCH;
```

This code is used in §46.

§**49.** Now for the related, but slightly simpler, case of matching the name of a KOV. Suppose we are parsing "award 5 points" against

> To award (N - a number) points: ...

Here `found` will be the actual constant value 5, and `expected` the generic constant value with KOV "number".

A phrase which returns a value must have its own return value's data type checked. Unfortunately we can't do that yet: we want to wait until recursive type-checking has removed incorrect invocations before drawing a conclusion about the return data type of the phrase.

⟨Step (f.2) Exception: when expecting a generic or actual CONSTANT 49⟩ ≡

```
LOG_STAGE("(f.2)");
if ((species_is(expected, CONSTANT_SPC)) &&
    (spec_is_evaluating(found)) &&
    (found != expected)) {
    if (species_is(found, PHRASE_TO_DECIDE_VALUE_SPC)) {
        LOGIF(INVOCATIONS, "(f.2) exempting phrase from return value checking for now\n");
    } else {
        switch (can_we_match_value_descriptions(found, expected)) {
            case NEVER_MATCH: ⟨Fail with a mismatched value problem message 50⟩;
            case SOMETIMES_MATCH:
                best_result = SOMETIMES_MATCH;
                LOGIF(INVOCATIONS, "dropping to sometimes level\n");
                break;
            case ALWAYS_MATCH: break;
        }
    }
    exceptional_case = TRUE;
}
```

This code is used in §45.

§**50.** This is the error message a typical C compiler's type-checker would issue; it says the value has the wrong kind.

⟨Fail with a mismatched value problem message 50⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
quote_type_of(3, expected);
if (species_is(found, LOCAL_VARIABLE_SPC)) {
    kind_of_value *kov = kov_of_local(spec_get_data(found, LOCAL_NUMBER_SPDATA));
    quote_kov(4, kov);
    handmade_problem(_P_(C7LocalMismatch));
    issue_problem_segment(
        "You wrote %1, but '%2' is a temporary name for %4 (created by 'let' "
        "or 'repeat'), whereas I was expecting to find %3 there.");
    issue_problem_end();
} else {
    quote_kov(4, spec_evaluates_to(found));
    handmade_problem(_P_(C7TypeMismatch));
    issue_problem_segment(
        "You wrote %1, but '%2' has the wrong kind of value: %4 rather than %3.");
```

```
        issue_problem_end();
    }
    return NEVER_MATCH;
```

This code is used in §49.

§**51.** We now apply the main rule, supposing that neither of the exceptional cases has intervened to stop us getting here. The found and expected specifications must have the same family and, unless the expected species is `UNKNOWN`, the same species as well.

⟨Step (f.3) Main rule 51⟩ ≡

```
    LOG_STAGE("(f.3)");
    int mtf = spec_get_family(found), stf = spec_get_species(found);
    int mte = spec_get_family(expected), ste = spec_get_species(expected);
    if ((mtf != mte) || ((ste != UNKNOWN) && (stf != ste)))
        ⟨Fail with a catch-all typechecking problem message 52⟩;
```

This code is used in §45.

§**52.** This is the general-purpose Problem message to which the type-checker resorts when it has nothing more specific to say.

⟨Fail with a catch-all typechecking problem message 52⟩ ≡

```
    THIS_IS_AN_ORDINARY_PROBLEM;
    quote_source(1, current_sentence);
    quote_words(2, found->word_ref1, found->word_ref2);
    quote_type_of(3, expected);
    quote_type_of(4, found);
    handmade_problem(_P_(BelievedImpossible));          well, at any rate I haven't seen it lately
    issue_problem_segment(
        "You wrote %1, but '%2' seems to be %4, whereas I was expecting to "
        "find %3 there.");
    issue_problem_end();
    return NEVER_MATCH;
```

This code is used in §51.

§**53. (g) Recurse down to check arguments.** We have now agreed that the current node in the type tree checks correctly. It remains only to see that any arguments also check, and this is where recursion comes in.

⟨Step (g) Recurse down to check arguments 53⟩ ≡

```
    LOG_STAGE("(g)");
    if ((species_is(found, LOGICAL_AND_SPC)) ||
        (species_is(found, LOGICAL_OR_SPC)))
        ⟨Step (g.1) Check individual conditions in a compound one 54⟩
    else {
        int i, an_arg_failed = FALSE;
        for (i=0; i<spec_get_argc(found); i++) {
            specification *ith_argument = spec_get_argument(found, i);
            if (ith_argument) {
                int rv = NEVER_MATCH;
                if (!(spec_is_UNKNOWN(ith_argument)))
                    rv = typecheck_recursive(ith_argument, ith_argument, 2, depth+1);
                if (rv != ALWAYS_MATCH) an_arg_failed = TRUE;
```

```
            }
        }
        if (species_is(found, LIST_ENTRY_SPC))
            ⟨Step (g.2) Check arguments of a list entry 55⟩;
        if (species_is(found, PROPERTY_VALUE_SPC))
            ⟨Step (g.3) Check arguments of a property value 56⟩;
        if (an_arg_failed) return NEVER_MATCH;
    }
```

This code is used in §13.

§**54.** LOGICAL_AND_SPC and LOGICAL_OR_SPC each take two arguments, both conditions, and we want to typecheck those against "condition".

⟨Step (g.1) Check individual conditions in a compound one 54⟩ ≡

```
    LOG_STAGE("(g.1)");
    specification *cond_spec = new_generic_CONDITION_type();
    if (typecheck_recursive(spec_get_argument(found, 0),
        cond_spec, problem_threshold, depth+1) != ALWAYS_MATCH)
            return NEVER_MATCH;
    if (typecheck_recursive(spec_get_argument(found, 1),
        cond_spec, problem_threshold, depth+1) != ALWAYS_MATCH)
            return NEVER_MATCH;
```

This code is used in §53.

§**55.** For a list entry, we have to have a list and an index.

⟨Step (g.2) Check arguments of a list entry 55⟩ ≡

```
    LOG_STAGE("(g.2)");
    kind_of_value *kov1 = spec_evaluates_to(spec_get_argument(found, 0));
    kind_of_value *kov2 = spec_evaluates_to(spec_get_argument(found, 1));
    if (kovcon_get_base(kov1) == NULL) {
        THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
        sentence_problem(_P_(C7EntryOfNonList),
            "that doesn't make sense to me as a list entry",
            "since the entry is taken from something which isn't a list.");
        return NEVER_MATCH;
    }
    if (is_kova(kov2, NUMBER_TY) == FALSE) {
        THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
        sentence_problem(_P_(C7NonNumericListEntry),
            "that doesn't make sense to me as a list entry",
            "because the indication of which entry is not a number. "
            "For instance, 'entry 3 of L' is allowed, but not 'entry "
            "\"six\" of L'. (List entries are numbered 1, 2, 3, ...)");
        return NEVER_MATCH;
    }
```

This code is used in §53.

§**56.** For a property value, we have to have a property and an owner (perhaps an object, perhaps a value).

⟨Step (g.3) Check arguments of a property value 56⟩ ≡
```
LOG_STAGE("(g.3)");
specification *the_property = spec_get_argument(found, 0);
kind_of_value *kov1 = spec_evaluates_to(the_property);
if (is_kova(kov1, PROPERTY_TY) == FALSE) ⟨Issue a "not a property" problem message 57⟩;
property_name *prn = PROPERTY_spec_to_property_name(the_property);
if (prn == NULL)
    internal_error("null property name in type checking");
if (prn_is_either_or(prn)) ⟨Issue a "not a value property" problem message 58⟩;
specification *the_owner = spec_get_argument(found, 1);
kind_of_value *kov2 = spec_evaluates_to(the_owner);
if (kov2) {
    int owner_is_object = is_kova(kov2, OBJECT_TY);
    int owner_should_be_value = prn_belongs_to_value(prn);
    if ((owner_should_be_value == FALSE) && (owner_is_object == FALSE))
        ⟨Issue a problem message for using a value's property of an object 59⟩;
    if ((owner_should_be_value) && (owner_is_object))
        ⟨Issue a problem message for using an object's property of a value 60⟩;
} else {
    ⟨Issue a problem message for being too vague about the owner 61⟩;
}
```

This code is used in §53.

§**57.** Inform constructs property-value specifications quite carefully, and I think it's only possible for the typechecker to see one where the property isn't a property when recovering from other problems.

⟨Issue a "not a property" problem message 57⟩ ≡
```
THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
quote_words(3, the_property->word_ref1, the_property->word_ref2);
handmade_problem(_P_(C7PropertyOfNonProperty));
issue_problem_segment(
    "In the sentence %1, it looks as if you intend '%2' to be a property "
    "of something, but there is no such property as '%3'.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §56.

§58.

⟨Issue a "not a value property" problem message 58⟩ ≡
```
THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
handmade_problem(_P_(C7EitherOrAsValue));
issue_problem_segment(
    "In the sentence %1, it looks as if you intend '%2' to be the value "
    "of a property of something, but that property has no value: it's "
    "something which an object either is or is not.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §56.

§59.

⟨Issue a problem message for using a value's property of an object 59⟩ ≡
```
THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
if (the_owner->word_ref1 >= 0) {
    quote_words(3, the_owner->word_ref1, the_owner->word_ref2);
    handmade_problem(_P_(C7PropertyOfNonObject));
    issue_problem_segment(
        "In the sentence %1, it looks as if you intend '%2' to be a property, "
        "but '%3' is not an object.");
    issue_problem_end();
} else {
    handmade_problem(_P_(BelievedImpossible));
    issue_problem_segment(
        "In the sentence %1, it looks as if you intend '%2' to be a property, "
        "but if so it is unclear to what object it would belong.");
    issue_problem_end();
}
return NEVER_MATCH;
```

This code is used in §56.

§60.

⟨Issue a problem message for using an object's property of a value 60⟩ ≡
```
THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, prn->word_ref1, prn->word_ref2);

issue_problem_segment(
    "In the sentence %1, it looks as if you are applying '%2' "
    "to an object, but it is really a property of a value.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §56.

§**61.**

⟨Issue a problem message for being too vague about the owner 61⟩ ≡

```
THIS_IS_A_GROSSER_THAN_GROSS_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, found->word_ref1, found->word_ref2);
if (spec_get_described_kind(the_owner))
    quote_object(3, spec_get_described_kind(the_owner));
else
    quote_words(3, the_owner->word_ref1, the_owner->word_ref2);
handmade_problem(_P_(C7PropertyOfKind));
if (found->word_ref1 >= 0)
    issue_problem_segment(
        "In the sentence %1, it looks as if you intend '%2' to be a property, "
        "but '%3' is not specific enough about who or what the owner is. ");
else
    issue_problem_segment(
        "In the sentence %1, it looks as if you intend to look up a property "
        "of something, but '%3' is not specific enough about who or what "
        "the owner is. ");
issue_problem_segment(
    "%PSometimes this mistake is made because Inform mostly doesn't understand "
    "the English language habit of referring to something indefinite by a "
    "common noun - for instance, writing 'change the carrying capacity of "
    "the container to 10' throws Inform because it doesn't understand "
    "that 'the container' means one which has been discussed recently.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §56.

§**62.** Rule (h). It's a bit of a curiosity that this is done in the type-checker, but here we go, just the same. We will reject the use of "end if" outside of an "if", and apply similar constraints on other structural phrases.

⟨Step (h) Police the global structure of phrase bodies 62⟩ ≡

```
LOG_STAGE_LEFT("(h)");
char *block_name = name_of_current_block();
LOGIF(INVOCATIONS, "Current block: <%s>\n", (block_name)?(block_name):"none");
⟨Step (h.1) Rulebook outcomes are legal only in rules belonging to rulebooks having them 63⟩;
⟨Step (h.2) "Otherwise" can only be used in an "if" 64⟩;
⟨Step (h.3) A switch case must have a value of the right kind 65⟩;
⟨Step (h.4) An "end structure" phrase can only occur at the end of the right structure 66⟩;
```

This code is used in §13.

§63.

⟨Step (h.1) Rulebook outcomes are legal only in rules belonging to rulebooks having them 63⟩ ≡

```
if (species_is(found, RULEBOOK_OUTCOME_PHRASE_SPC)) {
    named_rulebook_outcome *nrbo = RETRIEVE_FROM_SPEC(found, named_rulebook_outcome);
    if (rb_allow_outcome(nrbo)) return ALWAYS_MATCH;
    THIS_IS_AN_ORDINARY_PROBLEM;
    sentence_problem(_P_(C7MisplacedRulebookOutcome),
        "this is a rulebook outcome which can only be used in rules "
        "belonging to rulebooks which recognise it",
        "and is not meaningful in general phrases or other rules. (For "
        "instance, the outcome 'persuasion succeeds' is allowed in a persuasion "
        "rule, but not anywhere else.)");
    return NEVER_MATCH;
}
```

This code is used in §62.

§64.

⟨Step (h.2) "Otherwise" can only be used in an "if" 64⟩ ≡

```
if (species_is(found, OTHERWISE_SPC)) {
    if (block_name == NULL) {
        THIS_IS_AN_ORDINARY_PROBLEM;
        sentence_problem(_P_(C7OtherwiseWithoutIf),
            "this is an 'else' or 'otherwise' with no matching 'if' (or 'unless')",
            "which must be wrong.");
        return NEVER_MATCH;
    }
    if ((strcmp(block_name, "if") != 0) && (strcmp(block_name, "unless") != 0)) {
        THIS_IS_AN_ORDINARY_PROBLEM;
        quote_source(1, current_sentence);
        quote_text(2, block_name);
        handmade_problem(_P_(C7OtherwiseInNonIf));
        issue_problem_segment(
            "The 'else' or 'otherwise' here did not make sense inside a "
            "'%2' structure: it's provided for 'if' (or 'unless').");
        issue_problem_end();
        return NEVER_MATCH;
    }
}
```

This code is used in §62.

§**65.**

⟨Step (h.3) A switch case must have a value of the right kind 65⟩ ≡

```
if ((species_is(found, CASE_SPC)) && (spec_get_argc(found) > 0)) {
    kind_of_value *switch_kov = kov_for_current_block();
    kind_of_value *case_kov = spec_get_kind_of_value(spec_get_argument(found, 0));
    LOGIF(INVOCATIONS, "(h.3) switch kov is $u, case kov is $u\n", switch_kov, case_kov);
    if (case_kov == NULL) {
        THIS_IS_AN_ORDINARY_PROBLEM;
        quote_source(1, current_sentence);
        quote_kov(2, switch_kov);
        handmade_problem(_P_(C7CaseValueNonConstant));
        issue_problem_segment(
            "The case %1 is required to be a constant value, rather than "
            "something which has different values at different times: "
            "specifically, it has to be %2.");
        issue_problem_end();
        return NEVER_MATCH;
    }
    if (can_we_cast_kovs(case_kov, switch_kov) != ALWAYS_MATCH) {
        THIS_IS_AN_ORDINARY_PROBLEM;
        quote_source(1, current_sentence);
        quote_kov(2, case_kov);
        quote_kov(3, switch_kov);
        handmade_problem(_P_(C7CaseValueMismatch));
        issue_problem_segment(
            "The case %1 has the wrong kind of value for the possibilities "
            "being chosen from: %2 instead of %3.");
        issue_problem_end();
        return NEVER_MATCH;
    }
}
```

This code is used in §62.

§**66.** This used to be a much-seen problem message, until Inform moved to Pythonesque structure-by-indentation. Nowadays "end if", "end while" and such are automatically inserted into the stream of commands, always in the right place, and always passing these checks. But the problem messages are kept for the sake of old-format source text, and for refuseniks.

⟨Step (h.4) An "end structure" phrase can only occur at the end of the right structure 66⟩ ≡

```
if (species_is(found, END_BLOCK_SPC)) {
    if (block_name == NULL) {
        THIS_IS_AN_ORDINARY_PROBLEM;
        if (problem_count == 0)
            sentence_problem_with_note(_P_(C7EndWithoutBegin),
                "this is an 'end' with no matching 'begin'",
                "which should not happen: every phrase like 'if ... begin;' "
                "should eventually be followed by its bookend 'end if'. "
                "It makes no sense to have an 'end ...' on its own.",
                "Perhaps the problem is actually that you opened several "
                "such begin... end 'blocks' and accidentally closed them "
                "once too many? This is very easily done.");
        else problem_count++;
```

```
            return NEVER_MATCH;
        } else {
            phrase *ended = RETRIEVE_FROM_SPEC(found, phrase);
            if (strcmp(lw_array[ended->type_data.words[0]].lw_text, block_name) != 0) {
                THIS_IS_AN_ORDINARY_PROBLEM;
                quote_source(1, current_sentence);
                quote_text(2, block_name);
                quote_source(3, start_of_current_block());
                handmade_problem(_P_(C7WrongEnd));
                issue_problem_segment(
                    "You wrote %1, but the end I was expecting next was 'end %2', "
                    "finishing the block you began with %3.");
                issue_problem_end();
                return NEVER_MATCH;
            }
        }
    }
```

This code is used in §62.

§**67.** Rule (i). This is the big one. It's applied whenever `found` has an invocation list.

```
⟨Step (i) Typecheck the invocations, choosing among them 67⟩ ≡
    invocation_list *found_invl = spec_invocation_list(found);
    invocation *list_of_invocations_to_test[MAX_INVOCATIONS_PER_PHRASE];
    int test_count = 0;
    int issue_interesting_problems = FALSE;
    int current_group = -1;
    int invocation_list_passes = FALSE;
    phrase *ph;
    ⟨Step (i.1) Set up the list of invocations to test 68⟩;
    ⟨Step (i.2) Type-check each invocation in turn 70⟩;
    if (problems_issued_during_typechecking()) return NEVER_MATCH;
    if (invocation_list_passes) ⟨Step (i.3) Preserve successful invocations 96⟩
    else ⟨Step (i.4) All invocations failed error 104⟩;
```

This code is used in §13.

§68. Phrase definitions are kept in a linked list with a total ordering which properly contains the partial ordering in which $P_1 \leq P_2$ if they are lexically identical and if each parameter of P_1 provably, at compile time, also satisfies the requirements for the corresponding parameter of P_2. They have already been lexically parsed in that order, so the list of invocations (which will have accumulated during parsing) is also in that same order. Now this is nearly the correct order for type-checking. But we make one last adjustment: the phrase being compiled is moved to the back of the list. This is to make recursion always the last thing checked, so that later rules can override earlier ones but still make use of them.

The following amounts to an $O(G^2)$ sorting algorithm, where G is the number of groups in the invocation list, but the coefficient is very low and G small: for everything except text, $G = 1$, and otherwise G is the number of pieces of text or substitutions in a double-quoted literal text. This seldom exceeds 10, in practice.

⟨Step (i.1) Set up the list of invocations to test 68⟩ ≡

```
LOG_STAGE("(i.1)");
INVOCATION_VARIABLE(inv);
int g = -1, g_max = 0;
for (g = 0; g <= g_max; g++) {
    LOOP_THROUGH_INVOCATION_LIST(inv, found_invl) {
        int n = inv_get_group(inv);
        if (n > g_max) g_max = n;
        if ((g == n) && (inv->phrase_invoked != phrase_being_compiled))
            ⟨Add this invocation to the list of test cases 69⟩;
    }
    LOOP_THROUGH_INVOCATION_LIST(inv, found_invl) {
        int n = inv_get_group(inv);
        if ((g == n) && (inv->phrase_invoked == phrase_being_compiled))
            ⟨Add this invocation to the list of test cases 69⟩;
    }
}
if (test_count != length_of_invocation_list(found_invl))
    internal_error("invocation list broken");
```

This code is used in §67.

§69.

⟨Add this invocation to the list of test cases 69⟩ ≡

```
if (test_count >= MAX_INVOCATIONS_PER_PHRASE) internal_error("overrun");
list_of_invocations_to_test[test_count++] = inv;
inv_clear_flag(inv, TESTED_INVFLAG);
inv_clear_flag(inv, PASSED_INVFLAG);
inv_clear_flag(inv, UNPROVEN_INVFLAG);
inv_clear_flag(inv, GROSSLY_FAILED_INVFLAG);
inv_clear_flag(inv, INTERESTING_PROBLEM_INVFLAG);
```

This code is used in §68.

§**70.** Now we work through the list of tests, which is in a sequence of groups numbered 0, 1, 2, ... Each group must produce at least one invocation passing at least at the "sometimes" level marked by the `UNPROVEN_INVFLAG`, or else the whole specification fails its match. Within each group, the first proven match stops our work, since we can never need lower-priority interpretations.

⟨Step (i.2) Type-check each invocation in turn 70⟩ ≡

```
    LOG_STAGE("(i.2)");
    STREAM_INDENT(dl);
    int ref, skip_rest_of_group = FALSE, passed_in_group = 0;
    for (ref = 0, current_group = -1; ref<test_count; ref++) {
        invocation *inv = list_of_invocations_to_test[ref];

    first_in_group = TRUE;
```

This code is used in §70.

§72.

⟨Describe the result for this particular invocation 72⟩ ≡
```
char *verdict = "Failed";
if (inv_test_flag(inv, PASSED_INVFLAG)) verdict = "Passed";
if (inv_test_flag(inv, UNPROVEN_INVFLAG)) verdict = "Passed (with qualifications)";
if (inv_test_flag(inv, GROSSLY_FAILED_INVFLAG)) verdict = "Failed grossly";
LOGIF(INVOCATIONS, "%s: P%d: $e\n", verdict, ref, inv);
```

This code is used in §70.

§73.

⟨Summarise the results in the debugging log 73⟩ ≡
```
int g = -1, i;
for (i=0; i<test_count; i++) {
    invocation *inv = list_of_invocations_to_test[i];
    if (g != inv_get_group(inv)) { g = inv_get_group(inv); LOGIF(INVOCATIONS, "| "); }
    if (inv_test_flag(inv, TESTED_INVFLAG) == FALSE) { LOGIF(INVOCATIONS, "- "); }
    else if (inv_test_flag(inv, UNPROVEN_INVFLAG)) { LOGIF(INVOCATIONS, "? "); }
    else if (inv_test_flag(inv, GROSSLY_FAILED_INVFLAG)) { LOGIF(INVOCATIONS, "g "); }
    else if (inv_test_flag(inv, PASSED_INVFLAG)) { LOGIF(INVOCATIONS, "p "); }
    else { LOGIF(INVOCATIONS, "f "); }
}
LOGIF(INVOCATIONS, "|\n");
```

This code is used in §70.

§74.

⟨Test the current invocation and set its results flags accordingly 74⟩ ≡
```
int invocation_passed = TRUE, with_qualifications = FALSE;
int no_gross_problems_thrown_before = no_gross_problems_thrown;
LOGIF(INVOCATIONS, "(P%d) Trying invocation <$W>: $e\n",
    ref, inv->invocation_w1, inv->invocation_w2, inv);
⟨Type-check this particular invocation 75⟩;
inv_set_flag(inv, TESTED_INVFLAG);
if (invocation_passed) {
    inv_set_flag(inv, PASSED_INVFLAG);
    if (with_qualifications) inv_set_flag(inv, UNPROVEN_INVFLAG);
} else if (no_gross_problems_thrown > no_gross_problems_thrown_before)
    inv_set_flag(inv, GROSSLY_FAILED_INVFLAG);
```

This code is used in §70,107,70,107,70.

§**75.** We can now forget about groups, and the rest of the list, and concentrate only on the current invocation `inv`. To fail it, we have to clear the `invocation_passed` flag; the failure will be deemed gross if and only if gross problem messages are called for during the checking process. We accept matches of arguments at the "sometimes" level, but need to set the `with_qualifications` flag if any arise.

We are *not* allowed to return from the routine here, because no matter how bad this particular invocation looks, others might be better. So we issue problem messages using the following macro only.

```
define THIS_IS_AN_INTERESTING_PROBLEM
    inv_set_flag(inv, INTERESTING_PROBLEM_INVFLAG);
    invocation_passed = FALSE;
    if (issue_interesting_problems)
```

⟨Type-check this particular invocation 75⟩ ≡

```
    ph = inv->phrase_invoked;
    inv->kov_resulting = phtd_get_return_kov(&(ph->type_data));
    if (phtd_is_any_let_phrase(&(ph->type_data))) {
        requested.local_initial_value = inv_get_token_as_parsed(inv, 1);
        requested.recently_discovered_KOV = NULL;
        LOGIF(INVOCATIONS, "Setting let-value to $S\n", requested.local_initial_value);
    }
    int arithmetical_phrase = FALSE;
    if ((ph->type_data.arithmetical_operation >= 0) &&
        (ph->type_data.arithmetical_operation < NO_OPERATIONS)) arithmetical_phrase = TRUE;
    are the arguments of the right kind?
    if (invocation_passed) ⟨Step (i.2.1) Take care of polymorphic phrases 76⟩;
    if (invocation_passed) ⟨Step (i.2.2) Take care of monomorphic phrases 84⟩;
    if (invocation_passed) ⟨Step (i.2.3) Match type templates in the argument specifications 85⟩
    if (invocation_passed) ⟨Step (i.2.4) Match KOVs in assignment phrases 86⟩;
    if this evaluates something, is it a value of the right kind?
    if (invocation_passed) ⟨Step (i.2.5) Check kind of value returned 92⟩;
    are there any special rules about invoking this phrase?
    if (invocation_passed) ⟨Step (i.2.6) Check any phrase options 93⟩;
    if (invocation_passed) ⟨Step (i.2.7) Worry about self in say property of 94⟩;
    if (invocation_passed) ⟨Step (i.2.8) Worry about using a phrase outside of the control structure it belongs to 95⟩;
```

This code is used in §74.

§**76.** "Polymorphic" here means that the phrase (i) produces a value, and (ii) that the kind of this value depends on the kinds of its arguments. Inform supports only a few polymorphic phrases, all clearly declared as such in the Standard Rules, and they come in two sorts: those marked with a "polymorphism exception", and those marked as "arithmetic operations".

⟨Step (i.2.1) Take care of polymorphic phrases 76⟩ ≡

```
LOG_STAGE("(i.2.1)");
switch (ph->type_data.polymorphism_exception) {
    case -1: break;                          this is the default value, for unexceptional phrases
    case 0: ⟨Step (i.2.1.1) "List of D" has KOV list-of-K 77⟩; break;
    case 1: ⟨Step (i.2.1.2) "A random D" has KOV K 78⟩; break;
    default: internal_error("Unknown polymorphism exception"); break;
}
if (ph->type_data.arithmetical_operation == TOTAL_OPERATION)
    ⟨Step (i.2.1.3) "Total P of O" has KOV the KOV of P 79⟩
else if (arithmetical_phrase) ⟨Step (i.2.1.4) Dimension-check arithmetic phrases 81⟩;
```

This code is used in §75.

§**77.** Exception 0 arises for "list of D", where D describes some domain: for instance, "the list of colours", which constructs the list of all valid colours and returns it as a value. Clearly "list of D" returns a value which needs to be "list of K" where K is the KOV of the members of the domain D – hence the polymorphism.

⟨Step (i.2.1.1) "List of D" has KOV list-of-K 77⟩ ≡

```
LOG_STAGE("(i.2.1.1)");
specification *domain_description = inv_get_token_as_parsed(inv, 0);
kind_of_value *K;
if (spec_is_generic_CONSTANT(domain_description))
    K = kov_when_VALUE_is_evaluated(domain_description);
else K = spec_get_described_kov(domain_description);
inv->kov_resulting = kov_list_of(K);
requested.recently_discovered_KOV = inv->kov_resulting;
LOGIF(INVOCATIONS, "'List of D' polymorphism exception: $u\n", inv->kov_resulting);
```

This code is used in §76.

§**78.** Exception 1 is similar, but simpler: the KOV of "a random D" is the same as the KOV of the members of the domain D.

⟨Step (i.2.1.2) "A random D" has KOV K 78⟩ ≡

```
LOG_STAGE("(i.2.1.2)");
specification *domain_description = inv_get_token_as_parsed(inv, 0);
kind_of_value *K;
if (spec_is_generic_CONSTANT(domain_description))
    K = kov_when_VALUE_is_evaluated(domain_description);
else K = spec_get_described_kov(domain_description);
inv->kov_resulting = K;
requested.recently_discovered_KOV = inv->kov_resulting;
LOGIF(INVOCATIONS, "'A random D' polymorphism exception: $u\n", inv->kov_resulting);
```

This code is used in §76.

§**79.** For instance, the KOV of "total carrying capacity of people in the Dining Room" is a number, because the KOV of the property "carrying capacity" is "number".

⟨Step (i.2.1.3) "Total P of O" has KOV the KOV of P 79⟩ ≡
```
LOG_STAGE("(i.2.1.3)");
specification *P = inv_get_token_as_parsed(inv, 0);
if (spec_is_CONSTANT_of_kova(P, PROPERTY_TY)) {
    property_name *prn = PROPERTY_spec_to_property_name(P);
    if (prn_is_value_property(prn)) inv->kov_resulting = prn_get_kind_of_value(prn);
    else {
        THIS_IS_AN_INTERESTING_PROBLEM {
            sentence_problem(_P_(C7TotalEitherOr),
                "this seems to be an attempt to total up an either/or property",
                "and by definition such a property has nothing to total.");
        }
    }
} else ⟨Fail the invocation for totalling something other than a property 80⟩;
```

This code is used in §76.

§**80.** The problem message here is to help what turns out to be quite a popular mistake. (Perhaps we should simply implement column-totalling and be done with it.)

⟨Fail the invocation for totalling something other than a property 80⟩ ≡
```
if (is_kova(spec_get_kind_of_value(P), TABLE_COLUMN_TY)) {
    THIS_IS_AN_INTERESTING_PROBLEM {
        sentence_problem(_P_(C7TotalTableColumn),
            "this seems to be an attempt to total up the column of a table",
            "whereas it's only legal to use 'total' for properties.");
    }
}
invocation_passed = FALSE;
```

This code is used in §79.

§**81.** For instance, the following blocks an attempt to add a number to a text.

⟨Step (i.2.1.4) Dimension-check arithmetic phrases 81⟩ ≡
```
LOG_STAGE("(i.2.1.4)");
int op_number = ph->type_data.arithmetical_operation;
LOGIF(INVOCATIONS, "(P%d) Arithmetic operation <op-%d>\n", ref, op_number);
specification *L, *R;
kind_of_value *kov_wanted, *left_kov, *right_kov, *kov_produced;
⟨Work out the KOVs of the operands, and what we want, and what we get 82⟩;
if (kov_produced) inv->kov_resulting = kov_produced;
else ⟨Fail the invocation for a dimensional problem 83⟩;
```

This code is used in §76.

§**82.** For the way this is actually worked out, see the section on "Dimensions".

⟨Work out the KOVs of the operands, and what we want, and what we get 82⟩ ≡

```
L = inv_get_token_as_parsed(inv, 0);
left_kov = fix_arithmetic_operand(L, depth);
if (arithmetic_op_is_unary(op_number)) {
    R = NULL; right_kov = NULL;
} else {
    R = inv_get_token_as_parsed(inv, 1); right_kov = fix_arithmetic_operand(R, depth);
}
kov_wanted = spec_get_kind_of_value(expected);
kov_produced = arithmetic_on_kovs(left_kov, right_kov, op_number);
```

This code is used in §81.

§**83.** Note that "value" – the vaguest KOV of all – might come up here as a result of some problem evaluating one of the operands, which has already been reported in a problem message; so we only issue this problem message when L and R are more definite.

⟨Fail the invocation for a dimensional problem 83⟩ ≡

```
if ((left_kov) && (is_kova(left_kov, ANY_VALUE_TY) == FALSE) &&
    (right_kov) && (is_kova(right_kov, ANY_VALUE_TY) == FALSE)) {
    THIS_IS_AN_INTERESTING_PROBLEM {
        quote_source(1, current_sentence);
        quote_words(2, L->word_ref1, L->word_ref2);
        quote_words(3, R->word_ref1, R->word_ref2);
        quote_spec(4, new_generic_CONSTANT_type(left_kov));
        quote_spec(5, new_generic_CONSTANT_type(right_kov));
        switch(op_number) {
            case PLUS_OPERATION: quote_text(6, "adding"); quote_text(7, "to"); break;
            case MINUS_OPERATION: quote_text(6, "subtracting"); quote_text(7, "from"); break;
            case TIMES_OPERATION: quote_text(6, "multiplying"); quote_text(7, "by"); break;
            case DIVIDE_OPERATION:
            case REMAINDER_OPERATION: quote_text(6, "dividing"); quote_text(7, "by"); break;
            case APPROXIMATION_OPERATION: quote_text(6, "rounding"); quote_text(7, "to");
break;
        }
        handmade_problem(_P_(C7BadArithmetic));
        issue_problem_segment(
            "You wrote %1, but that seems to involve %6 %4 ('%2') %7 %5 ('%3'), "
            "which is not good arithmetic.");
        issue_problem_end();
    }
}
invocation_passed = FALSE;
```

This code is used in §81.

§84. I really have no idea if computer scientists ever use the word "monomorphic" for a function whose type is definitely known, but I suppose it's the opposite of being polymorphic. Anyway, this is the general case: almost all phrases fall into this category, including all phrases created outside the Standard Rules.

The deal is simply that every argument must match its specification. For instance, if `inv` is an invocation of this phrase:

> To truncate (L - a list of values) to (N - a number) entries: ...

...then token 0 must match "list of values", and token 1 must match "number".

⟨Step (i.2.2) Take care of monomorphic phrases 84⟩ ≡

```
if (!arithmetical_phrase) {
    LOG_STAGE("(i.2.2)");
    int i, exit_at_once = FALSE;
    for (i=0; i<inv_get_number_tokens(inv); i++) {
        specification ith_token = *(inv_get_token_as_parsed(inv, i));
        specification *ith_spec = ph->type_data.tokens_spec[i];
        inv_set_token_check_to_do(inv, i, NULL);
        switch(typecheck_recursive(&ith_token, ith_spec, 2, depth+1)) {
            case NEVER_MATCH:
                LOGIF(INVOCATIONS, "(i.2.2) on $S failed at token %d\n", found, i);
                invocation_passed = FALSE;
                if (problems_issued_during_typechecking()) exit_at_once = TRUE;
                break;
            case SOMETIMES_MATCH:
                LOGIF(INVOCATIONS, "(i.2.2) on $S qualified at token %d\n", found, i);
                inv_set_token_check_to_do(inv, i, ith_spec);
                with_qualifications = TRUE;
                break;
        }
        if (exit_at_once) break;
        if (spec_test_flag(&ith_token, COERCED_SPFLAG)) {
            LOGIF(INVOCATIONS, "(i.2.2) duplicates $S\n", &ith_token);
            inv_set_token_as_parsed(inv, i, spec_copy(&ith_token));
        } else {
            LOGIF(INVOCATIONS, "(i.2.2) declines to duplicate $S\n", &ith_token);
            *(inv_get_token_as_parsed(inv, i)) = ith_token;
        }
    }
    if (invocation_passed) LOGIF(INVOCATIONS, "(i.2.2) argument type matching passed\n");
}
```

This code is used in §75.

§**85.** For templates and the meaning of `prototype_checking_pass`, see the section on "Kinds of Value". But basically this handles the matching of an invocation against a definition like:

To remove (N - value = kov reference 1) from (L - list of values = list of kov marker 1): ...

⟨Step (i.2.3) Match type templates in the argument specifications 85⟩ ≡

```
    LOG_STAGE("(i.2.3)");
    int template_present = FALSE, i, exit_at_once = FALSE;
    for (i=0; i<inv_get_number_tokens(inv); i++)
        if (ph->type_data.tokens_template[i]) template_present = TRUE;
    if (template_present) {
        for (prototype_checking_pass = 1; prototype_checking_pass <= 2; prototype_checking_pass++)
{
            LOGIF(INVOCATIONS, "(i.2.3) prototype check pass %d\n", prototype_checking_pass);
            for (i=0; i<inv_get_number_tokens(inv); i++) {
                if (ph->type_data.tokens_template[i]) {
                    switch(can_we_cast_kovs(
                        spec_evaluates_to(inv_get_token_as_parsed(inv, i)),
                        ph->type_data.tokens_template[i])) {
                        case NEVER_MATCH:
                            LOGIF(INVOCATIONS, "(i.2.3) failed at token %d\n", i);
                            invocation_passed = FALSE;
                            if (problems_issued_during_typechecking()) exit_at_once = TRUE;
                            break;
                        case SOMETIMES_MATCH:
                            best_result = SOMETIMES_MATCH;
                            we won't use with_qualifications – we don't know exactly what they
are
                            LOGIF(INVOCATIONS, "(i.2.3) dropping to sometimes at token %d\n",
i);
                            break;
                        case ALWAYS_MATCH:
                            break;
                    }
                }
                if (exit_at_once) break;
            }
            if (exit_at_once) break;
        }
        if (invocation_passed) LOGIF(INVOCATIONS, "(i.2.3) prototype check passed\n");
    }
```

This code is used in §75.

§**86.** Although we don't implement it with prototypes as such, there's a similar constraint on the arguments of an assignment. If we are checking an invocation against:

To let (t - existing variable) be (u - assignable-value): ...

then we have so far checked that argument 0 is indeed the name of a variable which already exists, and that argument 1 does indeed evaluate a permissible value. But suppose the invocation is

let N be "there'll be no mutant enemy";

where N has already been created as a variable of KOV "number". This clearly has to be rejected, as it would violate type-safety. Step (i.2.4) therefore makes sure that all assignments match the KOV of the new value against the KOV of the storage item to which it is being written.

A reasonable question might be why we don't implement this using the prototype system of (i.2.3), thus removing a rule from this already-complex algorithm. The answer is that we would need much more elaborate syntax to express the specifications of the tokens (e.g., "value = kov reference 1 table-reference"), which would be icky, and that we would get less helpful problem messages when an invocation failed.

⟨Step (i.2.4) Match KOVs in assignment phrases 86⟩ ≡

```
LOG_STAGE("(i.2.4)");
if (ph->type_data.assignment_exception) {
    specification *target = inv_get_token_as_parsed(inv, 0);
    specification *new_value = inv_get_token_as_parsed(inv, 1);
    specification *target_spec = ph->type_data.tokens_spec[0];
    specification *new_value_spec = ph->type_data.tokens_spec[1];
    if (is_kova(spec_get_kind_of_value(target_spec), OBJECT_TY))
        ⟨Step (i.2.4.1) Police an assignment to an object 87⟩;
    if (family_is(target_spec, STORAGE_FMY))
        ⟨Step (i.2.4.2) Police an assignment to a storage item 91⟩;
}
```

This code is used in §75.

§**87.** It doesn't always look like an assignment, but a phrase such as:

change the Marble Door to open;

has similar type-checking needs.

⟨Step (i.2.4.1) Police an assignment to an object 87⟩ ≡

```
LOG_STAGE("(i.2.4.1)");
world_object *target_wo = wo_of_CONSTANT_OBJECT_if_any(target);
property_name *prn = NULL;
int make_check = FALSE;
if (is_kova(spec_get_kind_of_value(new_value_spec), ANY_VALUE_TY))
    ⟨Maybe we're changing an object to a value of a KOV coinciding with a property 88⟩;
if (spec_is_CONSTANT_of_kova(new_value_spec, PROPERTY_TY))
    ⟨Maybe we're changing an object to a named either/or property or condition state 89⟩;
if (make_check)
    ⟨Check that the property exists and that the object is allowed to have it 90⟩;
```

This code is used in §86.

§**88.** There are actually two definitions like this in the Standard Rules:

[1] To change (o - object) to (w - value): ...

[2] To change (o - object) to (p - property): ...

Here's the code for [1], the less obvious case. This is needed for something like

change the canvas to blue;

where "blue" is a constant colour, and "colour" is both a KOV and also a property. (This case really is an assignment – it assigns the value "blue" to the colour property of the canvas.)

⟨Maybe we're changing an object to a value of a KOV coinciding with a property 88⟩ ≡

```
LOG_STAGE("(i.2.4.1a)");
quantity *q = spec_get_constant_quantity_if_any(new_value);
if (q == NULL) invocation_passed = FALSE;
else {
    prn = kov_get_coinciding_property(qty_kind_of_value(q));
    if (prn == NULL) invocation_passed = FALSE;
    else make_check = TRUE;
}
```

This code is used in §87.

§**89.** And here's the simpler case, [2]. A small quirk here is that it will also pick up "change the Atrium to spiffy" in the following:

Atrium is a room. The Atrium can be spiffy, cool or lame.

When play begins: change the Atrium to spiffy.

...where "spiffy" is deemed a property rather than a constant value of a KOV because of the way the condition of the Atrium is declared. This is a little bit horrid, but works fine in practice. (If we try to accommodate this case within (1.2.4.1a), which might seem more logical, we run into trouble because the property name is cast to a property value of `self` when being typechecked against "value".)

⟨Maybe we're changing an object to a named either/or property or condition state 89⟩ ≡

```
LOG_STAGE("(i.2.4.1b)");
if (spec_is_CONSTANT_of_kova(new_value, PROPERTY_TY))
    prn = PROPERTY_spec_to_property_name(new_value);
else if (number_of_adjectives_applied_to(new_value) == 1) {
    adjectival_phrase *aph = get_adjective_from_list_entry(first_adjective_list_entry(new_value));
    if (aph_has_ENUMERATIVE_meaning(aph))
        prn = kov_get_coinciding_property(qty_kind_of_value(aph_has_ENUMERATIVE_meaning(aph)));
    else if (aph_has_EORP_meaning(aph))
        prn = aph_has_EORP_meaning(aph);
}
make_check = TRUE;
```

This code is used in §87.

§**90.** We do something quite interesting here, if the object is not explicitly named: we deliberately allow an assignment which may not be type-safe, and without even dropping to the "sometimes" level. This is for phrases like so:

change the item to closed;

Here the author seems to know what he's doing, and is pretty sure that the current contents of "item" will accept closure. All we can prove is that "item" contains an object (or perhaps `nothing`, the non-object). But we allow the assignment because it will compile to code which will issue a helpful run-time problem message if it goes wrong.

⟨Check that the property exists and that the object is allowed to have it 90⟩ ≡

```
LOGIF(INVOCATIONS, "Property appears to be $Y\n", prn);
if (prn == NULL) {
    THIS_IS_AN_INTERESTING_PROBLEM {
        quote_source(1, current_sentence);
        quote_words(2, target->word_ref1, target->word_ref2);
        quote_words(3, new_value->word_ref1, new_value->word_ref2);
        handmade_problem(_P_(BelievedImpossible));      the parser seems not to allow these
        issue_problem_segment(
            "You wrote %1, asking to change the object '%2'. This would "
            "make sense if '%3' were an either/or property like 'open' "
            "(or perhaps a named property value like 'blue') - but it "
            "isn't, so the change makes no sense.");
        issue_problem_end();
    }
}
if ((target_wo) && (prn) && (does_object_provide(target_wo, prn) == FALSE)) {
    THIS_IS_AN_INTERESTING_PROBLEM {
        quote_source(1, current_sentence);
        quote_words(2, target->word_ref1, target->word_ref2);
        quote_property(3, prn);
        handmade_problem(_P_(C7PropertyNotAllowed));
        issue_problem_segment(
            "You wrote %1, but '%2' is not allowed to have the property '%3'.");
        issue_problem_end();
    }
}
```

This code is used in §87.

§**91.** This is more straightforward, with just a tiny glitch to make the rules tougher on variables which hold text to be parsed. (Because the regular rules for exchanging the subtly different forms of text which a double-quoted literal can mean are too generous.)

⟨Step (i.2.4.2) Police an assignment to a storage item 91⟩ ≡

```
kind_of_value *kov_wanted, *kov_found;
LOGIF(INVOCATIONS, "Check assignment of $S to $S\n", new_value, target);
switch(spec_get_storage_form(target_spec)) {
    case LOCAL_VARIABLE_SPC: quote_text(6, "the name of"); break;
    case PROPERTY_VALUE_SPC: quote_text(6, "a property whose kind of value is"); break;
    case NONLOCAL_VARIABLE_SPC: quote_text(6, "a variable whose kind of value is"); break;
    case TABLE_ENTRY_SPC: quote_text(6, "a table entry whose kind of value is"); break;
    case LIST_ENTRY_SPC: quote_text(6, "an entry in a list whose kind of value is"); break;
}
kov_wanted = spec_evaluates_to(target);
kov_found = spec_evaluates_to(new_value);
if (requested.recently_discovered_KOV) kov_found = requested.recently_discovered_KOV;
if (((is_kova(kov_wanted, UNDERSTANDING_TY)) &&
    (is_kova(kov_found, UNDERSTANDING_TY) == FALSE))
    || (can_we_cast_kovs(kov_found, kov_wanted) == NEVER_MATCH)) {
    THIS_IS_AN_INTERESTING_PROBLEM {
        quote_source(1, current_sentence);
        quote_words(2, target->word_ref1, target->word_ref2);
        quote_kov(3, spec_evaluates_to(target));
        quote_words(4, new_value->word_ref1, new_value->word_ref2);
        quote_kov(5, spec_evaluates_to(new_value));
        handmade_problem(_P_(C7ChangeToWrongValue));
        issue_problem_segment(
            "You wrote %1, but '%2' is supposed to be "
            "%6 %3, so it cannot be set equal to %4, whose kind is %5.");
        issue_problem_end();
    }
}
```

This code is used in §86.

§**92.** Suppose we have something like this:

award the current action points;

and we are typechecking `found` as "the current action" (a phrase deciding a value) against `expected` as "number", the parameter expected in "award (N - a number) points".

No matter how peculiar this invocation of `found` was, we have now successfully worked out the kind of the value it would return if compiled, and this is stored in `inv->kov_resulting`. We now check to see if this matches the KOV expected – in this example, it won't, because a stored action does not cast to a number.

⟨Step (i.2.5) Check kind of value returned 92⟩ ≡

```
LOG_STAGE("(i.2.5)");
if (species_is(found, PHRASE_TO_DECIDE_VALUE_SPC)) {
    kind_of_value *kov_needed = spec_get_kind_of_value(expected);
    int outcome_test = ALWAYS_MATCH;
    if (kov_needed) {
        LOGIF(INVOCATIONS, "(P%d) Checking returned $u against desired $u\n",
            ref, inv->kov_resulting, kov_needed);
```

```
            outcome_test = can_we_cast_kovs(inv->kov_resulting, kov_needed);
        }
        switch (outcome_test) {
            case NEVER_MATCH: invocation_passed = FALSE; break;
            case SOMETIMES_MATCH: best_result = SOMETIMES_MATCH; break;
        }
    }
```

This code is used in §75.

§**93.** The final stage in type-checking a phrase is to ensure that any phrase options are properly used.

⟨Step (i.2.6) Check any phrase options 93⟩ ≡

```
    LOG_STAGE("(i.2.6)");
    if ((invocation_passed) && (inv->phrase_options_invoked)) {
        int ow1, ow2;
        inv_get_phrase_options(inv, &ow1, &ow2);
        int cso = ph_To_check_supplied_options(ph,
            (problem_threshold >= 2)?TRUE:FALSE, inv, ow1, ow2);
        if (cso == FALSE) invocation_passed = FALSE;
    }
```

This code is used in §75.

§**94.** A say phrase which involves a property of something implicitly changes the scope for any vaguely described properties within the text supplied as that property (if it is indeed text). We have to mark any such property, and any such say. For instance, suppose we are typechecking

[1] "Oh, look: [initial appearance of the escritoire]"

and the initial appearance in question is:

[2] "A small, portable writing desk holding up to [carrying capacity] letters."

Printing text [2], it's important for the `self` object to be the escritoire, which might not be the case otherwise; so during the printing of [1], we have to change `self` temporarily and restore it afterwards.

⟨Step (i.2.7) Worry about self in say property of 94⟩ ≡

```
    LOG_STAGE("(i.2.7)");
    if ((ph->type_data.say_phrase) &&
        (inv_get_number_tokens(inv) == 1) &&
        (spec_get_storage_form(inv_get_token_as_parsed(inv, 0)) == PROPERTY_VALUE_SPC)) {
        spec_set_flag(inv_get_token_as_parsed(inv, 0), RECORD_AS_SELF_SPFLAG);
        inv_set_flag(inv, SAVE_SELF_INVFLAG);
    }
```

This code is used in §75.

§**95.** Some phrases are defined with a notation making them allowable only inside loops, or other control structures; for instance,

To break – in loop: ...

And here is where we check that "break" is indeed used only in a loop.

⟨Step (i.2.8) Worry about using a phrase outside of the control structure it belongs to 95⟩ ≡

```
LOG_STAGE("(1.2.8)");
if ((ph) && (ph->type_data.only_in_loop)) {
    LOGIF(INVOCATIONS, "Required to be inside loop body\n");
    if (inside_a_loop_body() == FALSE) {
        THIS_IS_AN_INTERESTING_PROBLEM {
            quote_source(1, current_sentence);
            quote_text(2, lw_array[ph->type_data.only_in_block_wn].lw_text);
            handmade_problem(_P_(C7CantUseOutsideLoop));
            issue_problem_segment(
                "%1 makes sense only inside a 'while' or 'repeat' loop.");
            issue_problem_end();
        }
    }
}
if ((ph) && (ph->type_data.only_in_block_wn >= 0)) {
    char *required = lw_array[ph->type_data.only_in_block_wn].lw_text;
    char *actual = name_of_current_block();
    LOGIF(INVOCATIONS, "Required to be inside block '%s'\n", required);
    if ((actual) && (strcmp(actual, "unless") == 0)) actual = "if";
    if ((actual == NULL) || (strcmp(required, actual) != 0)) {
        THIS_IS_AN_INTERESTING_PROBLEM {
            quote_source(1, current_sentence);
            quote_text(2, lw_array[ph->type_data.only_in_block_wn].lw_text);
            handmade_problem(_P_(C7CantUseOutsideStructure));
            issue_problem_segment(
                "%1 makes sense only inside a '%2' block.");
            issue_problem_end();
        }
    }
}
```

This code is used in §75.

§**96. Preserving successful invocations.** This is the happy ending, in which the phrase can probably be passed, though there are still a handful of pitfalls. We know definitely which phrase(s) to invoke for each group, and there's no group where everything failed.

⟨Step (i.3) Preserve successful invocations 96⟩ ≡

```
LOG_STAGE("(i.3)");
⟨Step (i.3.1) Create any requested local variable 97⟩;
⟨Step (i.3.2) Winnow the invocation list down to the survivors 102⟩;
```

This code is used in §67.

§**97.** Here's the usual way a local variable is made. One invocation we matched is for the phrase whose prototype reads:

To let (T - nonexisting variable) be (V - value): ...

To be definite, let's suppose we are working on:

let the magic word be "Shazam [turn count] times!";

The checking code above filled out a request when it handled the T argument, further down in the recursion from the current call, to say that a new local should be made. It set `requested.word_ref1` and `requested.word_ref2` to the word range "magic word", and `requested.KOV_from_prototype` to "value" – meaning that T's prototype did not require any specific KOV. (It would have been legal to write "To let (T - nonexisting number variable) be...", for instance, and then `requested.KOV_from_prototype` would be "number".) So in this case, at least, the prototype didn't tell us what the KOV of this local should be – we must deduce it from the initial value,

"Shazam [turn count] times!"

which is stored in `requested.local_initial_value`. It occasionally happens that we have already worked out some ingenious KOV for this as a result of a polymorphism exception or arithmetic rules, in which case `requested.recently_discovered_KOV` will be set. But more often not, and certainly not in this example.

⟨Step (i.3.1) Create any requested local variable 97⟩ ≡

```
LOG_STAGE("(i.3.1)");
if ((requested.word_ref1 >= 0) && (depth <= requested.depth_made_at) &&
    (!(TEST_COMPILATION_MODE(DO_NOT_CREATE_LOCAL_VARS_CMODE)))) {
    int w1 = requested.word_ref1, w2 = requested.word_ref2;          name of new local
    kind_of_value *kov = requested.KOV_from_prototype;                  and its KOV
    specification *initial_value = requested.local_initial_value;
    kind_of_value *discovered_kov = requested.recently_discovered_KOV;
    ⟨Empty any local variable request 8⟩;
    if ((is_kova(kov, ANY_VALUE_TY)) && (initial_value))
        ⟨Where no KOV was explicitly stated, infer this from the supplied initial value 98⟩;
    phrase_made_local = make_new_local(w1, w2, kov);
    KOV_of_recently_created_local = kov;
}
```

This code is used in §96.

§**98.** Unusually, it's legal for the initial value to be a generic constant –

let the magic digraph be an indexed text;

This doesn't give us an initial value as such, but it explicitly tells us the KOV, which is good enough.

Otherwise, we either know the KOV already from polymorphism calculations, or we can work it out by seeing what the initial value evaluates to.

But there's a wrinkle. The KOV of the initial value is not always the same as the KOV of a variable to store it in – we sometimes want to widen this. For instance, the KOV of

"Shazam [turn count] times!"

is "text-routine", meaning, text with substitutions in. We want to widen this to "text"; the widening is done by `kov_for_storage_to_hold`.

⟨Where no KOV was explicitly stated, infer this from the supplied initial value 98⟩ ≡

```
kind_of_value *seems_to_be;
```

```
if (discovered_kov)
    seems_to_be = discovered_kov;
else if (spec_is_generic_CONSTANT(initial_value))
    seems_to_be = spec_get_kind_of_value(initial_value);
else
    seems_to_be = spec_evaluates_to(initial_value);
LOGIF(LOCAL_VARIABLES, "New variable $W from $S seems to be: $u\n",
    w1, w2, initial_value, seems_to_be);
if (seems_to_be == NULL) ⟨Fail: the initial value of the local is unknown 99⟩;
if ((is_kovcon(seems_to_be)) &&
    (is_kova(kovcon_get_base(seems_to_be), NO_ENTRIES_TY)))
    ⟨Fail: the initial value of the local is the empty list 100⟩;
kov = kov_for_storage_to_hold(seems_to_be);
if (kov == NULL) ⟨Fail: the initial value can't be stored 101⟩;
LOGIF(LOCAL_VARIABLES, "Inferred the KOV: $u\n", kov);
```

This code is used in §97.

§**99.** So there are various things that can go wrong:

⟨Fail: the initial value of the local is unknown 99⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
quote_words(2, initial_value->word_ref1, initial_value->word_ref2);
handmade_problem(_P_(BelievedImpossible));
issue_problem_segment(
    "The phrase %1 tries to use 'let' to give a temporary name to a value, "
    "but the value ('%2') is one that I can't understand.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §98.

§**100.** Bet you didn't think of this one:

⟨Fail: the initial value of the local is the empty list 100⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
handmade_problem(_P_(C7CantLetEmptyList));
issue_problem_segment(
    "The phrase %1 tries to use 'let' to give a temporary name to the "
    "empty list '{ }', but because it's empty, I can't tell what kind of "
    "value the list should have. Try 'let X be a list of numbers' (or "
    "whatever) instead.");
issue_problem_end();
return NEVER_MATCH;
```

This code is used in §98.

§**101.** And some KOVs are just forbidden in storage, and can't even be widened to something legitimate ("property", for instance):

⟨Fail: the initial value can't be stored 101⟩ ≡
```
LOGIF(INVOCATIONS, "Unable to store the KOV: $u\n", kov);
THIS_IS_AN_ORDINARY_PROBLEM;
sentence_problem(_P_(C7BadLocalKOV),
    "this is a value which can't be given a temporary name",
    "using 'let'.");
return NEVER_MATCH;
```

This code is used in §98.

§**102.** To recap, each group in the list has been checked. Each group contains 1 or more invocations which passed; the last of these is either the end of the group, or an invocation which passed without qualification. Within each group, failed invocations are interleaved with passed ones, and there will also be unchecked invocations if they occurred after an unqualified pass. A typical group might produce:

```
f ? f g ? ? p - - -
```

We can now throw away the `f`, `g` and `-` invocations to leave just those which will be compiled:

```
? ? ? p
```

This will eventually result in a Resolver routine to check if the arguments allow the first invocation and run it if so; then the second; then the third; and, if those three fell through, run the fourth invocation without further checking. See "Compile Invocations" in Chapter 12.

⟨Step (i.3.2) Winnow the invocation list down to the survivors 102⟩ ≡
```
LOG_STAGE("(i.3.2)");
invocation_list *invl = new_invocation_list();
int nfi = 0, nfi_group = -1, number_ambiguity = FALSE;
INVOCATION_VARIABLE(inv);
LOOP_THROUGH_INVOCATION_LIST(inv, found_invl) {
    if (inv_test_flag(inv, PASSED_INVFLAG)) {
        int nti = inv_get_number_tokens(inv);
        if (nfi_group != inv_get_group(inv)) {
            nfi = nti;
            nfi_group = inv_get_group(inv);
        } else {
            if (nfi != nti) number_ambiguity = TRUE;
        }
        add_to_invocation_list(invl, inv);
    }
}
if (number_ambiguity) ⟨Issue the number ambiguity problem message 103⟩;
spec_set_invocation_list(found, invl);
found_invl = invl;
```

This code is used in §96.

§**103.** This is another sort of error which couldn't happen with a conventional programming language – in C, for instance, it's syntactically obvious how many arguments a function call has, because the brackets and commas are unambiguous. But in Inform, there are no reserved tokens of syntax acting like that. So we could easily have two accepted invocations in the list which have different numbers of arguments to each other, and there's no way safely to adjudicate that at run-time.

⟨Issue the number ambiguity problem message 103⟩ ≡

```
THIS_IS_AN_ORDINARY_PROBLEM;
quote_source(1, current_sentence);
handmade_problem(_P_(C7UnequalValueAmbiguity));
issue_problem_segment(
    "The phrase %1 is ambiguous in a way that I can't disentangle. "
    "It has more than one plausible interpretation, such that it "
    "would only be possible to tell which is valid at run-time: "
    "ordinarily that would be fine, but because the different "
    "interpretations are so different (and involve different "
    "numbers of values being used) there's no good way to cope. "
    "Try rewording one of the phrases which caused this clash: "
    "there's a good chance the problem will then go away.");
issue_problem_end();
it_is_not_worth_adding = TRUE;
int i = 0;
LOOP_THROUGH_INVOCATION_LIST(inv, invl) {
    i++;
    quote_number(1, &i);
    quote_invocation(2, inv);
    issue_problem_begin("*");
    issue_problem_segment("%1. %2");
    issue_problem_end();
}
describe_inv_token_problems();
it_is_not_worth_adding = FALSE;
return NEVER_MATCH;
```

This code is used in §102.

§**104. Problems, problems, problems.** Where (i.3) was the happy ending, this is the unhappy one. We are now in a situation where none of the invocations in group `current_group` passed, so that it's impossible compile legal code which would do anything at run-time. Thus `found` unequivocally fails to match, so it would be legitimate simply to perform `return NEVER_MATCH` here.

But of course we actually want to produce helpful problem messages. It's not entirely clear how best to do this. Often, when `found` fails, it fails for seven different reasons – each different possibility fails for a different cause. We want, somehow, to guess which was the most likely to have been intended and to report the problem with that one.

⟨Step (i.4) All invocations failed error 104⟩ ≡

```
LOG_STAGE("(i.4)");
THIS_IS_AN_ORDINARY_PROBLEM;
if (current_group < 0) return NEVER_MATCH;      just in case found had an empty invocation list
LOGIF(INVOCATIONS, "All invocations failed: issuing problem\n$E", found_invl);
invocation *first_inv_in_group = NULL;
invocation *first_failing_interestingly = NULL;
```

```
invocation *first_not_failing_grossly = NULL;
int say_w1 = -1, say_w2 = -1;
int list_includes_lets = FALSE;
int nongross_count = 0;
⟨Scan through the invocations in the problematic group, gathering information 105⟩;
invocation *most_likely_to_have_been_intended = NULL;
⟨Decide which invocation is the one most likely to have been intended 106⟩;
if (first_failing_interestingly)
    ⟨Re-typecheck the first interesting invocation, allowing interesting problems this time 107⟩
else if (most_likely_to_have_been_intended)
    ⟨Re-typecheck the tokens of the most likely invocation with silence off 108⟩
else {
    if (say_w1 >= 0) ⟨Issue a problem for a text substitution with multiple failed possibilities 109⟩
    else ⟨Issue a problem for a regular phrase with multiple failed possibilities 110⟩;
}
return NEVER_MATCH;
```

This code is used in §67.

§105.

⟨Scan through the invocations in the problematic group, gathering information 105⟩ ≡

```
int ref;
for (ref=0; ref<test_count; ref++) {
    invocation *inv = list_of_invocations_to_test[ref];
    if (inv_get_group(inv) == current_group) {
        if ((inv_test_flag(inv, INTERESTING_PROBLEM_INVFLAG)) &&
            (first_failing_interestingly == NULL)) first_failing_interestingly = inv;
        ph = inv->phrase_invoked;
        if (phtd_is_any_let_phrase(&(ph->type_data))) list_includes_lets = TRUE;
        if (first_inv_in_group == NULL) first_inv_in_group = inv;
        if (inv_test_flag(inv, GROSSLY_FAILED_INVFLAG) == FALSE) {
            first_not_failing_grossly = inv;
            if (phtd_is_a_say_X_phrase(&(ph->type_data))) {
                say_w1 = inv->invocation_w1; say_w2 = inv->invocation_w2;
            }
            nongross_count++;
        }
    }
}
```

This code is used in §104.

§106.

⟨Decide which invocation is the one most likely to have been intended 106⟩ ≡

```
if (first_failing_interestingly)
    most_likely_to_have_been_intended = first_failing_interestingly;
else if ((nongross_count > 1) && (list_includes_lets))
    most_likely_to_have_been_intended = first_not_failing_grossly;
else if (nongross_count == 1)
    most_likely_to_have_been_intended = first_not_failing_grossly;
else if ((nongross_count == 0) && (first_inv_in_group))
    most_likely_to_have_been_intended = first_inv_in_group;
```

This code is used in §104.

§107.

⟨Re-typecheck the first interesting invocation, allowing interesting problems this time 107⟩ ≡

```
issue_interesting_problems = TRUE;
invocation *inv = first_failing_interestingly;
int ref = 0;                                    will be shown in the debugging log as P0 now
⟨Test the current invocation and set its results flags accordingly 74⟩;
```

This code is used in §104.

§108.

⟨Re-typecheck the tokens of the most likely invocation with silence off 108⟩ ≡

```
int ec = problem_count;
ph = most_likely_to_have_been_intended->phrase_invoked;
int i;
for (i=0; i<inv_get_number_tokens(most_likely_to_have_been_intended); i++) {
    typecheck_recursive(inv_get_token_as_parsed(most_likely_to_have_been_intended, i),
        ph->type_data.tokens_spec[i], 0, depth+1);
    if (problem_count > ec) break;
}
if (problem_count == ec)
    sentence_problem(_P_(BelievedImpossible),
        "the ingredients in this phrase do not fit it",
        "but I am confused enough by this that I can't give a very helpful "
        "problem message. Sorry about that.");
```

This code is used in §104.

§**109.**

⟨Issue a problem for a text substitution with multiple failed possibilities 109⟩ ≡

```
if ([[say_w1, say_w2 == time]] || [[say_w1, say_w2 == the time]]) {
    sentence_in_detail_problem(_P_(C7Time2), say_w1, say_w2,
        "this asked to say 'time' itself",
        "rather than any specific time. (If you meant the current "
        "time, this is called 'time of day' in Inform to avoid "
        "confusing it with the various other meanings that the "
        "word 'time' can have.)");
    issue_problem_end();
    return NEVER_MATCH;
}
specification *say_text_as_value = parse_expression(say_w1, say_w2, TYPE_OR_VALUE_EXPCON);
kind_of_value *kov = spec_evaluates_to(say_text_as_value);
LOG("Say text $W; as value, $S; evaluating to $u\n",
    say_w1, say_w2, say_text_as_value, kov);
if (species_is(say_text_as_value, DESCRIPTION_SPC)) {
    sentence_in_detail_problem(_P_(C7SayDescription), say_w1, say_w2,
        "this asked to say something which describes items too vaguely",
        "and so does not (or not in an elementary enough way) tell "
        "me exactly which thing or room should have its name printed.");
    return NEVER_MATCH;
}
if (kov) {
    sentence_in_detail_problem(_P_(C7AllSayInvsFailed), say_w1, say_w2,
        "this asked to say something of a kind which can't be said",
        "or rather, printed. Although this problem can arise when you "
        "use complicated text substitutions which come in variant "
        "forms depending on the kinds of value used, far more often "
        "what this means is just that you tried to use a substituted "
        "value (e.g., in 'say \"The dial reads [V].\"') of a kind "
        "which could not be printed out. For instance, if V is a "
        "number or a piece of text, there is no problem: but if V "
        "is a parsing topic, say an entry in a 'topic' column of "
        "a table, then this problem will arise.");
    return NEVER_MATCH;
}
sentence_in_detail_problem(_P_(BelievedImpossible), say_w1, say_w2,
    "this asked to say something which I do not recognise",
    "either as a value or as one of the possible text substitutions.");
```

This code is used in §104.

§**110.**

⟨Issue a problem for a regular phrase with multiple failed possibilities 110⟩ ≡

```
handmade_problem(_P_(C7AllInvsFailed));
quote_source(1, current_sentence);
issue_problem_segment(
    "You wrote %1, which is a phrase that can be construed in more "
    "than one way. I tried the possibilities in the order numbered "
    "below, and would have accepted the first which successfully "
    "matched - but none of them did.");
issue_problem_end();
⟨Itemise the failed possibilities in a list 111⟩;
```

This code is used in §104.

§**111.** Where, at long, long last:

⟨Itemise the failed possibilities in a list 111⟩ ≡

```
it_is_not_worth_adding = TRUE;
int i;
for (i=1; i<=test_count; i++) {
    invocation *inv = list_of_invocations_to_test[i-1];
    if (inv_get_group(inv) == current_group) {
        quote_number(1, &i);
        quote_invocation(2, inv);
        issue_problem_begin("*");
        issue_problem_segment("%1. %2");
        issue_problem_end();
    }
}
describe_inv_token_problems();
it_is_not_worth_adding = FALSE;
```

This code is used in §110.

§**112.** In that final checklist of doomed possibility, the code to quote an invocation in a problem message will call `note_inv_token_text` for each parsed token. This remembers the token so that it can be explained in notes at the end of the big list; but each word range is remembered only once, for brevity. We don't gloss the meanings of literal constants like `26` or `"frog"` since these are glaringly obvious.

```
void note_inv_token_text(specification *found) {
    if ((spec_is_actual_CONSTANT_of_kova(found, NUMBER_TY)) ||
        (spec_is_actual_CONSTANT_of_kova(found, TEXT_TY))) return;
    inv_token_problem_token *itpt;
    LOOP_OVER(itpt, inv_token_problem_token)
        if ((itpt->word_ref1 == found->word_ref1) && (itpt->word_ref2 == found->word_ref2))
            return;
    itpt = CREATE(inv_token_problem_token);
    itpt->word_ref1 = found->word_ref1; itpt->word_ref2 = found->word_ref2;
    itpt->as_parsed = found; itpt->already_described = FALSE;
}
```

The function note_inv_token_text is called from 12/phtd.

§**113.** And this is the code which produces those glossary notes at the foot of the list.

```
void describe_inv_token_problems(void) {
    inv_token_problem_token *itpt;
    LOOP_OVER(itpt, inv_token_problem_token)
        if (itpt->already_described == FALSE) {
            itpt->already_described = TRUE;
            quote_words(1, itpt->word_ref1, itpt->word_ref2);
            quote_spec(2, itpt->as_parsed);
            issue_problem_begin("*");
            if (spec_is_evaluating(itpt->as_parsed)) {
                quote_kov(3, spec_evaluates_to(itpt->as_parsed));
                if (family_is(itpt->as_parsed, STORAGE_FMY))
                    issue_problem_segment("%1: %2, holding <i>%3</i>");
                else if (species_is(itpt->as_parsed, PHRASE_TO_DECIDE_VALUE_SPC))
                    issue_problem_segment("%1: %2, which results in <i>%3</i>");
                else
                    issue_problem_segment("%1: <i>%3</i>");
            } else {
                issue_problem_segment("%1: <i>%2</i>");
            }
            issue_problem_end();
        }
}
```

§**114.** That only leaves two little utility routines needed by the typechecker. The first of these does something substantive: it works out the KOV of an operand for an arithmetic operation.

```
kind_of_value *fix_arithmetic_operand(specification *operand, int depth) {
    if (spec_is_UNKNOWN(operand)) return NULL;
    specification *expected = operand;
    if (spec_is_CONSTANT_of_kova(operand, PROPERTY_TY)) {
        property_name *prn = spec_get_property_name_if_any(operand);
        if (prn_is_either_or(prn) == FALSE)
            expected = new_generic_CONSTANT_type(prn_get_kind_of_value(prn));
    }
    typecheck_recursive(operand, expected, 2, depth+1);
    return spec_evaluates_to(operand);
}
```

§**115.** The second utility fills in a note in a problem message, identifying which sub-parts of a compound condition were okay.

```
int issue_condition_error_bit(int w1, int w2) {
    if (is_list_divided(w1, w2, LOOK_FOR_AND + LOOK_FOR_OR)) {
        int lw1 = left_w1, lw2 = left_w2, rw1 = right_w1, rw2 = right_w2;
        int ok1 = issue_condition_error_bit(lw1, lw2);
        int ok2 = issue_condition_error_bit(rw1, rw2);
        if ((ok1) && (ok2)) return TRUE;
        return FALSE;
    }
    specification *clause = parse_expression(w1, w2, CONDITION_EXPCON);
    LOG("Condition clause $W = $S\n", w1, w2, clause);
    quote_words(4, w1, w2);
    if (spec_is_UNKNOWN(clause)) {
        clause = parse_expression(w1, w2, VALUE_EXPCON);
        if (spec_is_UNKNOWN(clause))
            issue_problem_segment("'%4' did not make sense; ");
        else
            issue_problem_segment(
                "'%4' only made sense as a value, which can't be used as "
                "a condition; ");
        return FALSE;
    }
    issue_problem_segment("'%4' was okay; ");
    return TRUE;
}
```

Invocations 7/inv

Purpose

Specifications which ask to use a phrase (which are "phrasal") indicate which phrase they intend by means of a list of "invocations". This list goes on to record the outcome of type-checking and provides instructions for code generation, as we see here.

7/inv.§1-14 Invocations themselves; §15 The implied newlines rule; §16-29 Invocation lists

---

Definitions

¶1. An invocation is a request to perform a particular phrase with a particular set of parameters. For instance, to perform "award (N - a number) points" with N set to 100.

Phrasal specifications, the ones which request the use of phrases, are built up by parsing the source text. This is often so ambiguous that it is impossible, at first, to narrow down the meaning to a single invocation, and so a phrasal specification builds up a list of possibilities.

The process of type-checking then strikes out definitely incorrect invocations, reducing the size of the list. If it becomes empty, the type-checker produces a Problem message; and similarly if it is impossible to remove mutually exclusive possibilities, for that is an ambiguity which Inform cannot resolve. But a successful type-checking may still leave more than one invocation in the list. There are two reasons for this:

(a) The list is bunched up into groups, which are numbered within the list from 0 upwards. Type-checking proceeds on each group independently. For most phrases, there is only one group – group 0 – and this business therefore has no effect, but it comes into its own for "say" phrases:

```
say "The time is ", time of day in words, " and you yawn."
```

Here what looks like a single phrase is in fact a sequence of three phrases, to say each of the items required, and this gives rise to groups 0, 1 and 2 in the invocation list: each group is treated as, in effect, a separate phrase in its own right. (Except that compilation of the final group has a small difference: that's where Inform appends a line break to text which, from its punctuation, apparently ends a sentence.) Groups are not interleaved: the list starts with the whole of group 0, then the whole of group 1, and so on.

(b) More interestingly, type-checking of any individual invocation has three possible outcomes, not two: as in Scottish law, the verdict can be guilty, not guilty, or "not proven". An invocation which can be disproved is thrown out of the list; but of the remainder, some are marked as proven to be correct, some as unproven. What this means is that we cannot tell at compile-time whether the usage is valid, but that we will be able to tell at run-time: so the code-generator must compile suitable disambiguation code to perform this run-time checking automatically.

¶2. Invocation lists are a little more abstractly wrapped up than most linked lists inside Inform, for ease of sorting:

```
typedef struct invocation_list {
    struct invocation_list_entry *list_head;
    struct invocation_list_entry *list_tail;          storing this makes Inform 5% faster on large sources
} invocation_list;
typedef struct invocation_list_entry {
    struct invocation *listed_inv;
    struct invocation_list_entry *next;
} invocation_list_entry;
```

The structure invocation_list is private to this section.
The structure invocation_list_entry is private to this section.

¶3. Just the same, that amounts to a simple linked list of these items:

```
typedef struct invocation {
    int inv_packed_record;                                    see below: a packed bitmap
    int invocation_w1, invocation_w2;                         text which this invocation interprets
    struct phrase *phrase_invoked;                            the phrase believed to be invoked
    struct invocation_options *phrase_options_invoked;        details of any options used
    int ssp_segment_count;                                    number of subsequent complex-say phrases in stream
    int ssp_closing_segment_wn;                               identifier for the last of these, or -1
    struct invocation_token_list *tokens_invoked;             linked list of these
    struct kind_of_value *kov_resulting;                      what if anything is returned
} invocation;
```

The structure invocation is shared with 7/vasp, 7/tc, 12/phtd, 12/cinv and 12/ambig.

¶4. Once again (as with specifications) we combine a host of flags in a single packed integer. A text of about 50,000 words produces 60,000 or so invocations, so economy is again worth a little trouble.

define SUPPRESS_IMPLIED_NEWLINES_INVFLAG 0x00000001 *in saying of literal text ending with punctuation*
define INSTEAD_INVFLAG 0x00000002 *has the "instead" keyword been prefixed or suffixed?*
define SAVE_SELF_INVFLAG 0x00000004 *save the* `self` *value on I6 stack around this invocation*
define PASSED_INVFLAG 0x00000008 *once type-checked: did this pass type checking?*
define UNPROVEN_INVFLAG 0x00000010 *once type-checked: will this need run-time checking?*
define GROSSLY_FAILED_INVFLAG 0x00000020 *once type-checked: oh, this one failed big time*
define TESTED_INVFLAG 0x00000040 *has been type-checked*
define INTERESTING_PROBLEM_INVFLAG 0x00000080 *an interesting problem message could be produced about the way this failed*
define BASE_OF_GROUP 0x00000100 *to which group this belongs: 0, 1, 2, ...*
define GROUP_MASK 0x000FFF00 *up to a possible 4095*
define BASE_OF_USN 0x00100000 *unsorted position in list, 0 up to 2047*
define USN_MASK 0x7FF00000

¶5. When necessary, and it usually isn't, an invocation has a packet of details attached about any phrase options used; for instance, in

    list the contents of the Box, with newlines;

this packet records the text "with newlines" along with its translation as a run-time bitmap (with just one bit set, since only one option is used).

```
typedef struct invocation_options {
    int options;                                        bitmap of any phrase options appended
    int options_invoked_w1, options_invoked_w2;         text of any phrase options appended
} invocation_options;
```

The structure invocation_options is private to this section.

¶6. An invocation can have an arbitrary number of "tokens". These are the arguments for the phrase being invoked; so for instance in

    a random number between 2 and 7;

token 0 is "2" and token 1 is "7". For each token we record both what we've parsed – these will each be constant `VALUE_SPC` specifications of KOV "number" – and also what match the type-checker needs to make for them to be valid.

```
typedef struct invocation_token_list {
    struct specification *token_as_parsed;              what we find
    struct specification *token_check_to_do;            what we need
    struct invocation_token_list *next;
} invocation_token_list;
```

The structure invocation_token_list is private to this section.

¶7. At first sight, the `invocation` structure appears to contain redundant information. And two of the fields are, in a way, redundant: the word number fields holding the text will, of course, be common to every entry in its group, so it is wasteful to store them so many times. But not very wasteful, by our standards, and the information is not easily available elsewhere, and it enables the debugging log to be much more informative about the working of our most complicated algorithms.

Similarly, `token_as_parsed` values look as if they too must be the same for everything in the group. But this is not always true. If we are interpreting the text "award 11 points" against possible phrases "award (O - an object)" and "award (N - a number) points", then the 0th token will be "11 points" (probably parsing to `UNKNOWN`) for the first invocation, and "11" (`NUMBER`) for the second. We shall of course accept the second. But the word positions for the 0th token, and its parsing values, are different. So each invocation in the list records its own `token_as_parsed` values.

¶8. On the other hand, `token_check_to_do` and `kov_resulting` look as if they are purely a function of the `phrase_invoked`, and therefore need not be in this structure at all. This is not true:

(i) A SP in `token_check_to_do` means that Inform has not yet satisfied itself that the `token_as_parsed` value matches properly. Once the type-checker does convince itself, the relevant entry in `token_check_to_do` is cleared to `NULL`. If every token can be cleared, the invocation is declared proven. But if the type-checker accepts the invocation but marks it as "not proven", one or more values remain as a sort of to-do list, telling the code generator what remains to be checked at run-time. So `token_check_to_do` really is associated with a specific invocation, and is not redundant.

(ii) Because arithmetic phrases return different data depending on the data types fed in, `kov_resulting` will be different for different invocations of, say, "+".

```
define LOOP_THROUGH_TOKENS_PARSED_IN_INV(inv, spec)
    int lttpii_counter, lttpii_upto = inv_get_number_tokens(inv);
    for (lttpii_counter=0,
        spec = (lttpii_counter < lttpii_upto)?
            inv_get_token_as_parsed(inv, lttpii_counter):NULL;
        lttpii_counter < lttpii_upto;
        lttpii_counter++,
        spec = (lttpii_counter < lttpii_upto)?
            inv_get_token_as_parsed(inv, lttpii_counter):NULL)
```

¶9.

```
define MAX_INVOCATIONS_PER_PHRASE 4096
```

---

§**1. Invocations themselves.** Are created thus:

```
invocation *new_invocation(void) {
    invocation *inv = CREATE(invocation);
    inv->inv_packed_record = 0;
    set_phrase_invoked(inv, NULL);
    inv->kov_resulting = NULL;
    inv->phrase_options_invoked = NULL;
    inv->ssp_segment_count = 0;
    inv->ssp_closing_segment_wn = -1;
    inv->invocation_w1 = -1; inv->invocation_w2 = -1;
    inv->tokens_invoked = NULL;
    return inv;
}
```

The function new_invocation is called from 12/phtd.

§**2.** And logging thus:

```
void log_invocation(invocation *inv) {
    int i;
    if (inv == NULL) { LOG("<null invocation>"); return; }
    if (inv->phrase_invoked == NULL) { LOG("<invocation of null phrase>"); return; }
    char *verdict = "untested";
    if (inv_test_flag(inv, TESTED_INVFLAG))         verdict = "failed  ";
    if (inv_test_flag(inv, PASSED_INVFLAG))         verdict = "proven  ";
    if (inv_test_flag(inv, UNPROVEN_INVFLAG))       verdict = "unproven";
    if (inv_test_flag(inv, GROSSLY_FAILED_INVFLAG)) verdict = "gross   ";
    LOG("group:%d %c%c [%04d] %s ", inv_get_group(inv),
        (inv_test_flag(inv, INSTEAD_INVFLAG))?'I':' ',
        (inv_test_flag(inv, SAVE_SELF_INVFLAG))?'s':' ',
        ph_sequence_count(inv->phrase_invoked),
        verdict);
    log_phrase_briefly(inv->phrase_invoked);
    for (i=0; i<inv_get_number_tokens(inv); i++) {
        LOG(" ($S", inv_get_token_as_parsed(inv, i));
        if (inv_get_token_check_to_do(inv, i)) LOG(" =? $S", inv_get_token_check_to_do(inv,
i));
        LOG(")");
    }
    int ow1, ow2;
    inv_get_phrase_options(inv, &ow1, &ow2);
    if (ow1 >= 0) LOG(" [0x%x $W]", inv_get_phrase_options_bitmap(inv), ow1, ow2);
}
```

The function log_invocation is called from 2/dl.

§**3.** The packed record of flags:

```
void inv_set_flag(invocation *inv, int flag) {
    if (inv == NULL) internal_error("tried to set flag for null inv");
    inv->inv_packed_record = (inv->inv_packed_record) | flag;
}
void inv_clear_flag(invocation *inv, int flag) {
    if (inv == NULL) internal_error("tried to clear flag for null inv");
    inv->inv_packed_record = (inv->inv_packed_record) & (~flag);
}
int inv_test_flag(invocation *inv, int flag) {
    int f = (inv)?(inv->inv_packed_record):0;
    if (f & flag) return TRUE;
    return FALSE;
}
```

The function inv_set_flag is called from 7/tc, 12/phtd and 12/cinv.
The function inv_clear_flag is called from 7/tc and 12/phtd.
The function inv_test_flag is called from 7/vasp, 7/tc and 12/cinv.

§**4.** And the group number, a non-negative integer:

```
int inv_get_group(invocation *inv) {
    if (inv == NULL) internal_error("tried to read group of null inv");
    return ((inv->inv_packed_record) & GROUP_MASK)/BASE_OF_GROUP;
}
void inv_set_group(invocation *inv, int g) {
    if (inv == NULL) internal_error("tried to set group of null inv");
    if ((g<0) || (g>4095)) internal_error("tried to set group out of range");
    inv->inv_packed_record = ((inv->inv_packed_record) & (~GROUP_MASK))
        + BASE_OF_GROUP*g;
}
```

The function inv_get_group is called from 5/mlc, 7/tc and 12/cinv.
The function inv_set_group is called from 5/mlc and 12/phtd.

§**5.** Likewise the unsorted position:

```
int inv_get_unsorted_position(invocation *inv) {
    if (inv == NULL) internal_error("tried to read USN of null inv");
    return ((inv->inv_packed_record) & USN_MASK)/BASE_OF_USN;
}
void inv_set_unsorted_position(invocation *inv, int n) {
    if (inv == NULL) internal_error("tried to set USN of null inv");
    if ((n<0) || (n>2047)) internal_error("tried to set USN out of range");
    inv->inv_packed_record = ((inv->inv_packed_record) & (~USN_MASK))
        + BASE_OF_USN*n;
}
```

§**6.** The word range:

```
void inv_set_word_range(invocation *inv, int w1, int w2) {
    if (inv == NULL) internal_error("tried to set word range of null inv");
    inv->invocation_w1 = w1; inv->invocation_w2 = w2;
}
```

The function inv_set_word_range is called from 12/phtd.

§**7.** The tokens. Recall that these are stored as a linked list; the following creates a new entry structure.

```
invocation_token_list *itl_new(void) {
    invocation_token_list *itl = CREATE(invocation_token_list);
    itl->token_as_parsed = NULL;
    itl->token_check_to_do = NULL;
    itl->next = NULL;
    return itl;
}
```

§**8.** However, we want to access it as if it were an array. (Speed is not too vital here, and the list sizes are almost always lower than 3.) So:

```
void inv_set_token_check_to_do(invocation *inv, int i, specification *spec) {
    int k;
    invocation_token_list *itl;
    if (i<0) internal_error("tried to set token out of range");
    if (inv->tokens_invoked == NULL) inv->tokens_invoked = itl_new();
    for (itl = inv->tokens_invoked, k = 0; itl; itl = itl->next, k++) {
        if (k == i) { itl->token_check_to_do = spec; return; }
        if (itl->next == NULL) itl->next = itl_new();
    }
}
void inv_set_token_as_parsed(invocation *inv, int i, specification *spec) {
    int k;
    invocation_token_list *itl;
    if (i<0) internal_error("tried to set token out of range");
    if (inv->tokens_invoked == NULL) inv->tokens_invoked = itl_new();
    for (itl = inv->tokens_invoked, k = 0; itl; itl = itl->next, k++) {
        if (k == i) { itl->token_as_parsed = spec; return; }
        if (itl->next == NULL) itl->next = itl_new();
    }
}
```

The function inv_set_token_check_to_do is called from 7/tc.

The function inv_set_token_as_parsed is called from 7/tc and 12/phtd.

§**9.** And similarly for reading them:

```
specification *inv_get_token_check_to_do(invocation *inv, int i) {
    int k;
    invocation_token_list *itl;
    for (itl = inv->tokens_invoked, k = 0; itl; itl = itl->next, k++)
        if (k == i) return itl->token_check_to_do;
    return NULL;
}
specification *inv_get_token_as_parsed(invocation *inv, int i) {
    int k;
    invocation_token_list *itl;
    for (itl = inv->tokens_invoked, k = 0; itl; itl = itl->next, k++)
        if (k == i) return itl->token_as_parsed;
    return NULL;
}
```

The function inv_get_token_check_to_do is called from 12/cinv and 12/ambig.

The function inv_get_token_as_parsed is called from 7/tc, 12/phtd and 12/cinv.

§**10.** The phrase, and the "instead" flag:

```
void set_phrase_invoked(invocation *inv, phrase *ph) {
    inv->phrase_invoked = ph;
}
void inv_set_instead_flag(invocation *inv, int t) {
    if (t) inv_set_flag(inv, INSTEAD_INVFLAG);
    else inv_clear_flag(inv, INSTEAD_INVFLAG);
}
```

The function set_phrase_invoked is called from 12/phtd.
The function inv_set_instead_flag is called from 5/mlc and 12/phtd.

§**11.** The following routine might become more interesting if we ever allowed variable-argument phrases like C's `printf`.

```
int inv_get_number_tokens(invocation *inv) {
    if (inv == NULL) internal_error("tried to read NTI of null inv");
    if (inv->phrase_invoked) return phtd_get_no_tokens(&(inv->phrase_invoked->type_data));
    return 0;
}
```

The function inv_get_number_tokens is called from 7/tc, 12/cinv and 12/ambig.

§**12.** The phrase options invoked:

```
void inv_set_phrase_options(invocation *inv, int w1, int w2) {
    if (inv->phrase_options_invoked == NULL) {
        inv->phrase_options_invoked = CREATE(invocation_options);
        inv->phrase_options_invoked->options = 0;
    }
    inv->phrase_options_invoked->options_invoked_w1 = w1;
    inv->phrase_options_invoked->options_invoked_w2 = w2;
}
```

The function inv_set_phrase_options is called from 12/phtd.

§**13.** Reading the word range:

```
void inv_get_phrase_options(invocation *inv, int *w1, int *w2) {
    if (inv->phrase_options_invoked == NULL) { *w1 = -1; *w2 = -1; }
    else {
        *w1 = inv->phrase_options_invoked->options_invoked_w1;
        *w2 = inv->phrase_options_invoked->options_invoked_w2;
    }
}
```

The function inv_get_phrase_options is called from 7/tc.

§**14.** The functional part is of course the bitmap, which we read and write thus. When no options are set, the bitmap is always 0.

```
int inv_get_phrase_options_bitmap(invocation *inv) {
    if (inv->phrase_options_invoked == NULL) return 0;
    return inv->phrase_options_invoked->options;
}
void inv_set_phrase_options_bitmap(invocation *inv, int further_bits) {
    if (further_bits == 0) return;
    if (inv->phrase_options_invoked == NULL) {
        inv->phrase_options_invoked = CREATE(invocation_options);
        inv->phrase_options_invoked->options_invoked_w1 = -1;
        inv->phrase_options_invoked->options_invoked_w2 = -1;
        inv->phrase_options_invoked->options = 0;
    }
    inv->phrase_options_invoked->options |= further_bits;
}
```

The function inv_get_phrase_options_bitmap is called from 12/cinv and 12/ambig.
The function inv_set_phrase_options_bitmap is called from 12/phod.

§**15. The implied newlines rule.** This is applied only when the invocation passes the following stringent test:

```
int inv_implies_newline(invocation *inv) {
    if (!(inv->phrase_invoked->type_data.say_phrase)) return FALSE;
    if (!(TEST_COMPILATION_MODE(IMPLY_NEWLINES_IN_SAY_CMODE))) return FALSE;
    if (inv_test_flag(inv, SUPPRESS_IMPLIED_NEWLINES_INVFLAG)) return FALSE;
    return TRUE;
}
```

The function inv_implies_newline is called from 12/cinv.

§**16. Invocation lists.** Specifications for phrases parsed in the source text often contain lists of invocations.

```
invocation_list *new_invocation_list(void) {
    invocation_list *invl = CREATE(invocation_list);
    invl->list_head = NULL; invl->list_tail = NULL;
    return invl;
}
```

The function new_invocation_list is called from 7/spec and 7/tc.

§**17.** Appending:

```
void append_invocation_list(invocation_list *to, invocation_list *from) {
    invocation_list_entry *ent;
    for (ent=from->list_head; ent; ent=ent->next)
        add_to_invocation_list(to, ent->listed_inv);
}
```

The function append_invocation_list is called from 5/mlc.

§**18.** New entries are always added to the ends.

```
void add_to_invocation_list(invocation_list *invl, invocation *inv) {
    invocation_list_entry *ent = CREATE(invocation_list_entry);
    ent->listed_inv = inv; ent->next = NULL;
    if (invl->list_head) invl->list_tail->next = ent;
    else invl->list_head = ent;
    invl->list_tail = ent;
}
```

The function add_to_invocation_list is called from 7/tc and 12/phtd.

§**19.** That completes the construction routines. Now, reading the length and first item:

```
int length_of_invocation_list(invocation_list *invl) {
    if (invl == NULL) return 0;
    int L = 0;
    invocation_list_entry *inve;
    for (inve = invl->list_head; inve; inve = inve->next) L++;
    return L;
}
invocation *first_in_invocation_list(invocation_list *invl) {
    if ((invl == NULL) || (invl->list_head == NULL)) return NULL;
    return invl->list_head->listed_inv;
}
```

The function length_of_invocation_list is called from 5/mlc and 7/tc.

§**20.** Sorting the invocations in a list is much more important than it may at first appear, since the sorted order is a precedence order for parsing purposes: that is, the earliest type-checked match is the one accepted, so that being sorted up front gives a possible interpretation of a phrase priority over those sorted to the back.

```
invocation **pigeon_holes = NULL;
int number_of_pigeon_holes = 0;
void sort_spec_invocation_list(invocation_list *invl) {
    int L = length_of_invocation_list(invl);
    ⟨Make sure there are at least L pigeonholes available for sorting into 21⟩;
    int i;
    invocation_list_entry *ent;
    for (i=0, ent=invl->list_head; (i<L) && (ent); i++, ent=ent->next) {
        pigeon_holes[i] = ent->listed_inv;
        inv_set_unsorted_position(pigeon_holes[i], (i>2047)?2047:i);
    }
    qsort(pigeon_holes, L, sizeof(invocation *), inv_comparison);
    for (i=0, ent=invl->list_head; i<L; i++, ent=ent->next)
        ent->listed_inv = pigeon_holes[i];
}
```

The function sort_spec_invocation_list is called from 5/mlc.

§**21.** We allocate 1000 pigeonholes in the first instance, then double each time we run out. (We will quite likely never run out, as 1000 is plenty. But we want to avoid all possible arbitrary limits.)

⟨Make sure there are at least L pigeonholes available for sorting into 21⟩ ≡

```
if (L > number_of_pigeon_holes) {
    number_of_pigeon_holes = 2*L;
    if (number_of_pigeon_holes < 1000)
        number_of_pigeon_holes = 1000;
    pigeon_holes =
        I7_calloc(number_of_pigeon_holes, sizeof(invocation *), INV_LIST_MREASON);
}
```

This code is used in §20.

§**22.** So much for the mechanism. The sorting order is specified by the following.

(a) We first group invocations by group number, which is simply a matter of the sequence in which they are to take effect.

(b) Then, within each group, we sort by logical priority. This is quite an expensive test, and therefore we effectively cache it by referring to the "sequence count" of the phrases instead: that is, to the numbered position in the logical priority ordering of the phrases. It's very important that each phrase has a unique sequence count value, because the C library sorting function `qsort` is unstable, so that it might arbitrarily rearrange invocations which happened to have equal group numbers and sequence counts – a problem because Inform's behaviour in terms of logical priority must be predictable.

(c) Our final sorting is on the original parsing sequence order, which we preserve in cases where two different invocations in the same group both invoke the same phrase (as for instance where "two minutes before two minutes before midnight" can be invoked either as "two minutes before (two minutes before midnight)" or "(two minutes before two minutes) before midnight"). The result is that the comparison function can return 0 only when the invocations are actually equal, so that the instability of the sorting algorithm does not produce any ambiguity in how Inform prioritises phrases.

```
int inv_comparison(const void *i1, const void *i2) {
    invocation **inv1s = (invocation **) i1; invocation *inv1 = *inv1s;
    invocation **inv2s = (invocation **) i2; invocation *inv2 = *inv2s;
    (a) sort by group
    int delta = inv_get_group(inv1) - inv_get_group(inv2);
    if (delta != 0) return delta;
    (b) sort by logical priority
    delta = ph_sequence_count(inv1->phrase_invoked) - ph_sequence_count(inv2->phrase_invoked);
    if (delta != 0) return delta;
    (c) sort by creation sequence
    return inv_get_unsorted_position(inv1) - inv_get_unsorted_position(inv2);
}
```

§**23.** The following macros abstract the process of looping through the invocations in a list. First, declaring the loop variable (actually three variables):

```
define INVOCATION_VARIABLE(inv)
    invocation *inv;
    invocation_list_entry *inv##_ent;
    int inv##_pos;
```

§**24.** The basic loop:

```
define LOOP_THROUGH_INVOCATION_LIST(inv, invl)
    for (inv##_ent = invl->list_head, inv##_pos = 0,
            inv = (inv##_ent)?inv##_ent->listed_inv:NULL;
        inv##_ent;
        inv##_ent = inv##_ent->next, inv##_pos++,
            inv = (inv##_ent)?inv##_ent->listed_inv:NULL)
```

§**25.** A loop which starts at position `from` (which must be another invocation variable) and runs for `size` items:

```
define LOOP_THROUGH_PART_OF_INVOCATION_LIST(inv, invl, p, from, size)
    for (inv##_pos = 0, inv##_ent = invl->list_head;
        ((inv##_pos<from) && (inv##_ent));
        inv##_pos++, inv##_ent = inv##_ent->next) ;
    for (inv##_pos = 0, p = 0, inv = (inv##_ent)?inv##_ent->listed_inv:NULL;
        ((inv##_pos<size) && (inv##_ent));
        inv##_pos++, p++, inv##_ent = inv##_ent->next,
            inv = (inv##_ent)?inv##_ent->listed_inv:NULL)
```

§**26.** A loop starting at `from` and running to the end of the list:

```
define LOOK_AHEAD_THROUGH_INVOCATION_LIST(inv, from, invl)
    for (inv##_ent = from##_ent, inv##_pos = from##_pos,
            inv = (inv##_ent)?inv##_ent->listed_inv:NULL;
        inv##_ent;
        inv##_ent = inv##_ent->next, inv##_pos++,
            inv = (inv##_ent)?inv##_ent->listed_inv:NULL)
```

§**27.** The log routines demonstrate the use of the basic macros:

```
void log_invocation_list(invocation_list *invl) {
    INVOCATION_VARIABLE(inv);
    LOG("Invocation list (%d):\n", length_of_invocation_list(invl));
    LOOP_THROUGH_INVOCATION_LIST(inv, invl)
        LOG("P%d: $e\n", inv_pos, inv);
}
```

The function log_invocation_list is called from 2/dl and 5/mlc.

§**28.** A more detailed version, which hierarchically shows the lists inside the invocations listed:

```
void log_invocation_list_in_detail(invocation_list *invl) {
    INVOCATION_VARIABLE(inv);
    LOG("Invocation list in detail (%d):\n", length_of_invocation_list(invl));
    LOOP_THROUGH_INVOCATION_LIST(inv, invl) {
        int j;
        LOG("P%d: $e\n", inv_pos, inv);
        for (j=0; j<inv_get_number_tokens(inv); j++) {
            specification *tok = inv_get_token_as_parsed(inv, j);
            LOG("  %d: $S\n", j, tok);
            if (spec_has_invocation_list(tok)) {
                STREAM_INDENT(dl);
                log_invocation_list_in_detail(spec_invocation_list(tok));
                STREAM_OUTDENT(dl);
            }
        }
    }
}
```

The function log_invocation_list_in_detail is called from 7/spec.

8 Assertions

`8/tass`: *Traverse for Assertions.w* To manage the overall process of traversing the parse tree for assertion sentences.

`8/sob`: *Subject and Object.w* To keep track of the implicit subject and object in assertion sentences, for use in understanding words like "it" and "here" in subsequent sentences.

`8/refpt`: *Refine Parse Tree.w* To determine which world objects are referred to by noun phrases such as "the table" and "a paper cup" found in assertion sentences being parsed.

`8/creat`: *The Creator.w* This is where all objects, kinds of object, and newly named values are made.

`8/mass`: *Make Assertions.w* To read assertion sentences, sort them according to a detailed grammatical classification and take the primary actions necessary either to generate problem messages, or to infer information.

`8/assem`: *Assemblies.w* To build the complex multi-object assemblies which result from allowing the source text to say things like "in every room is a vehicle".

`8/knowc`: *Character Knowledge.w* Character in the sense of the nature of things – both the kind of an object, but also more generally that it satisfies some proposition.

`8/knowp`: *Property Knowledge.w* This section draws inferences from assertions which seem to be about the properties of things, independent of their location.

`8/relv`: *Relation Knowledge.w* This section draws inferences about the relationships between objects or values.

`8/imp`: *Implications.w* To keep track of a dangerous form of super-assertion called an implication, which is allowed to generalise about properties.

Traverse for Assertions 8/tass

Purpose

To manage the overall process of traversing the parse tree for assertion sentences.

8/tass.¶3-0 The sentence handler tables; §3-10 Performing the main traverse

Definitions

¶1. Inferences are collected during two traverses of the parse tree, which are numbered in the following global variable.

```
int traverse;                                                    always 1 or 2
```

¶2. Sentence handlers provide an abstraction for the choice of what to do with each kind of sentence, on each traverse. This is really only a disguise for a couple of `switch` statements and a lot of function calls. The only real purpose is to make it easier to encapsulate code for one sort of sentence away from the others: if we were writing `C++` or Python, it would just be a method in the class for sentences.

Properly speaking, there can be sentence handlers for any node type at the children-of-root level of the parse tree, although we mostly use this for `SENTENCE_NT` nodes (and then we look further at the verb type in the `VERB_NT` first child). The main traverse is a two-pass operation, and we can supply a routine to do something with the node on either of the passes (or neither, or even both).

```
typedef struct sentence_handler {
    int sentence_node_type;                          usually but not always SENTENCE_NT
    int verb_type;                                   for those which are indeed SENTENCE_NT
    int handle_on_traverse;                          1 or 2 to restrict to that pass, or 0 for both
    void (*handling_routine)(struct parse_node *PN);                          or NULL not to handle
} sentence_handler;
```

The structure sentence_handler is private to this section.

¶3. The sentence handler tables.

define `MAX_OF_NTS_AND_VBS 64`

```
sentence_handler *how_to_handle_nodes[MAX_OF_NTS_AND_VBS];
sentence_handler *how_to_handle_sentences[MAX_OF_NTS_AND_VBS];
```

¶4. We recognise either node types `*_NT`, or node type `SENTENCE_NT` plus an associated verb number `*_VB`. The following macro registers a sentence handler by entering a pointer to it into one of the above tables:

```
define REGISTER_SENTENCE_HANDLER(sh_name) {
    sentence_handler *the_sh = &sh_name##_handler;
    if ((the_sh->sentence_node_type == SENTENCE_NT) && (the_sh->verb_type != -1))
        how_to_handle_sentences[the_sh->verb_type] = the_sh;
    else
        how_to_handle_nodes[the_sh->sentence_node_type] = the_sh;
}
```

---

§**1.** The actual handlers are mostly not declared here (indeed, that's the point of the whole exercise – to allow them to be decentralised). But we do need to know their names, so every `*_SH` constant below must correspond to a sentence handler structure called `*_SH_handler` defined somewhere else in NI.

```
int sentence_handlers_initialised = FALSE;
void initialise_sentence_handlers(void) {
    if (sentence_handlers_initialised) return;
    sentence_handlers_initialised = TRUE;
    ⟨Empty the sentence handler tables 2⟩;
    register_sentence_handlers();
}
```

§**2.** At this stage, all we do is empty the tables. The reason we have to delay before entering the valid handlers is that some of them will be defined in sections of NI appearing after this one in the code: since C requires all identifiers used to be predeclared, this means we can't enter the valid handlers until right at the end of NI. The routine which does so, `register_sentence_handlers`, consists only of a run of `REGISTER_SENTENCE_HANDLER` macro expansions and can be found in Chapter 14.

⟨Empty the sentence handler tables 2⟩ ≡

```
    int i;
    for (i=0; i<MAX_OF_NTS_AND_VBS; i++) {
        how_to_handle_nodes[i] = NULL;
        how_to_handle_sentences[i] = NULL;
    }
```

This code is used in §1.

§3. Performing the main traverse. The following routine is called twice, once with `pass` equal to 1, then with `pass` equal to 2.

`trace_sentences` is true between each pair of `TRACE_NT` nodes, if there are any: these arise from the special debugging sentence consisting only of an asterisk. When tracing, we print an account of what is being read to the debugging log (both here, and in more detail elsewhere), except that we don't bother to print details of the closing `TRACE_NT` node.

```
void traverse_for_assertions(int pass) {
    parse_node *p;
    new_discussion();                    clear memory of what the subject and object of discussion are
    traverse = pass;
    trace_sentences = FALSE;
    log_asterisked_parts_of_parse_tree("start of assertion traverse");
    initialise_sentence_handlers();                in case the sentence handler tables not made yet
    for (TREE_START(p); p; TREE_NEXT(p)) {
        finish_this_session_of_parsing();
        if ((trace_sentences) && (pn_get_node_type(p) != TRACE_NT))
            LOG("\n[$W]\n", p->word_ref1, p->word_ref2);
        ⟨If this sentence can be handled, then do so and continue 4⟩;
        log_subtree(p, 1);
        internal_error_on_node_type(p->down);
    }
}
```

The function traverse_for_assertions is called from 14/i6t.

§4. The outer `if` here should always be true: we verify that the node type is a valid index in the sentence handler tables, then that a sentence handler has indeed been registered for that type. If that should fail, there must be a bug somewhere, and we will throw an internal error.

However, it's entirely open for the sentence handler to choose to do nothing on either or both traverses, so the inner `if` can happily fail.

⟨If this sentence can be handled, then do so and continue 4⟩ ≡

```
    if (((pn_get_node_type(p) >= 0) && (pn_get_node_type(p) < MAX_OF_NTS_AND_VBS))
        && (how_to_handle_nodes[pn_get_node_type(p)])) {
        int desired = how_to_handle_nodes[pn_get_node_type(p)]->handle_on_traverse;
        if (((traverse == desired) || (desired == 0)) &&
            (how_to_handle_nodes[pn_get_node_type(p)]->handling_routine))
            (*(how_to_handle_nodes[pn_get_node_type(p)]->handling_routine))(p);
        continue;
    }
```

This code is used in §3.

§**5.** While most of the sentence handlers are scattered across the rest of NI, two will be given here. The first is the one which acts on `TRACE_NT` asterisks and switches tracing off and on:

```
sentence_handler TRACE_SH_handler =
    { TRACE_NT, -1, 0, switch_sentence_trace };
void switch_sentence_trace(parse_node *PN) {
    if (PN->word_ref2 > PN->word_ref1) {
        int tr = telemetry_recording;
        telemetry_recording = TRUE;
        write_telemetry_note(lw_array[PN->word_ref2].lw_text);
        telemetry_recording = FALSE;
        sentence_problem(_P_(C8TelemetryAccepted),
            "that's a message for the Author, not me",
            "so I'll note it down in the Telemetry file (if you're keeping "
            "one.)");
        telemetry_recording = tr;
    } else {
        trace_sentences = 1 - trace_sentences;
        if (traverse == 1) debug_log_tracing(trace_sentences, "Pass 1");
        else debug_log_tracing(trace_sentences, "Pass 2");
    }
}
```

§**6.** And the other is the sentence handler for `SENTENCE_NT` itself, which is special because it looks at the `VERB_NT` child of the sentence and then refers on to other sentence handlers accordingly:

```
sentence_handler SENTENCE_SH_handler =
    { SENTENCE_NT, -1, 0, handle_sentence_with_primary_verb };
void handle_sentence_with_primary_verb(parse_node *p) {
    prevailing_mood = UNKNOWN_CE;
    if (p->down == NULL) ⟨Handle a sentence with no primary verb 7⟩;
    internal_error_if_node_type_wrong(p->down, VERB_NT);
    prevailing_mood = pn_int_annotation(p->down, verbal_certainty_ANNOT);
    ⟨Issue problem message if either subject or object contains mismatched brackets 10⟩;
    ⟨Act on the primary verb in the sentence 8⟩;
}
```

§**7.** A sentence node with no children indicates that we couldn't find any verb earlier. This might just be a piece of quoted matter which is intended as the description or initial appearance of the most recent object, but in all other eventualities we must produce a "no such sentence" problem.

⟨Handle a sentence with no primary verb 7⟩ ≡

```
    if ((p->word_ref1 == p->word_ref2) &&
        (vocab_test_flags(p->word_ref1, TEXT_MC+TEXTWITHSUBS_MC))) {
        if (traverse == 2) set_appearance(p->word_ref1);
        return;
    }
    ⟨Issue problem message about not being able to find a verb 9⟩;
    return;
```

This code is used in §6.

§**8.** We now use the other sentence-handler table, with almost the same code as for the first (above). A small point of difference is that it's allowed for a valid verb number to have no handler: if so, we handle the verb by doing nothing on either traverse, of course.

⟨Act on the primary verb in the sentence 8⟩ ≡

```
int vn = pn_int_annotation(p->down, verb_id_ANNOT);
if ((vn < 0) || (vn >= MAX_OF_NTS_AND_VBS)) {
    LOG("Unimplemented verb %d\n", pn_int_annotation(p->down, verb_id_ANNOT));
    internal_error_on_node_type(p->down);
}
if (how_to_handle_sentences[vn]) {
    int desired = how_to_handle_sentences[vn]->handle_on_traverse;
    if (((traverse == desired) || (desired == 0)) &&
        (how_to_handle_sentences[vn]->handling_routine))
        (*(how_to_handle_sentences[vn]->handling_routine))(p);
}
```

This code is used in §6.

§**9.** The number of different cases this splits into is a typical example of how beta-testing puts emphasis on unexpected parts of the code: it never occurred to me in the original design that NI would be found so sensitive to punctuation errors as between comma, paragraph break and semicolon, nor that this would be the place where that sensitivity would begin to bite.

⟨Issue problem message about not being able to find a verb 9⟩ ≡

```
int i;
if [[p == before/every/after/when/instead/check/carry/report ...]]
    sentence_problem(_P_(C8RuleWithoutColon),
        "I can't find a verb that I know how to deal with, "
        "so can't do anything with this sentence. It looks "
        "as if it might be a rule definition",
        "but if so then it is lacking the necessary colon (or comma). "
        "The punctuation style for rules is 'Rule conditions: do this; "
        "do that; do some more.' Perhaps you used a full stop instead "
        "of the colon?");
else if [[p == if ...]]
    sentence_problem(_P_(C8IfOutsidePhrase),
        "I can't find a verb that I know how to deal with. This looks "
        "like an 'if' phrase which has slipped its moorings",
        "so I am ignoring it. ('If' phrases, like all other such "
        "instructions, belong inside definitions of rules or phrases - "
        "not as sentences which have no context. Maybe a full stop was "
        "accidentally used instead of semicolon, so that you "
        "inadvertently ended the last rule early?)");
else if [[p == ... COMMA ... : i]] sentence_problem(_P_(C8NoSuchVerbComma),
    "I can't find a verb here that I know how to deal with",
    "so I am ignoring this sentence altogether. (I notice there's a "
    "comma here, which is sometimes used to abbreviate rules which "
    "would normally be written with a colon - for instance, 'Before "
    "taking: say \"You draw breath.\"' can be abbreviated to 'Before "
    "taking, say...' - but that's only allowed for Before, Instead and "
    "After rules. I mention all this in case you meant this sentence "
    "as a rule in some rulebook, but used a comma where there should "
    "have been a colon ':'?");
```

```
    else sentence_problem(_P_(C8NoSuchVerb),
        "I can't find a verb here that I know how to deal with",
        "so I am ignoring this sentence altogether.");
```

This code is used in §7.

§**10.** Inform source text does not make much use of parentheses to group subexpressions, but the ability does exist, and we defend it a little here:

⟨Issue problem message if either subject or object contains mismatched brackets 10⟩ ≡

```
    if ((p->down->next) && (p->down->next->next) &&
        ((brackets_unbalanced(p->down->next->word_ref1,
        p->down->next->word_ref2)) ||
        (brackets_unbalanced(p->down->next->next->word_ref1,
        p->down->next->next->word_ref2)))) {
        quote_source(1, current_sentence);
        quote_words(2, p->down->next->word_ref2+1, p->down->next->word_ref2+1);
        quote_words(3, p->down->next->word_ref1, p->down->next->word_ref2);
        quote_words(4, p->down->next->next->word_ref1, p->down->next->next->word_ref2);
        handmade_problem(_P_(BelievedImpossible));
        if (p->down->next->next->word_ref1 >= 0)
            issue_problem_segment(
                "I must be misreading the sentence %1. The verb "
                "looks to me like '%2', but then the brackets don't "
                "match in what I have left: '%3' and '%4'.");
        else
            issue_problem_segment(
                "I must be misreading the sentence %1. The verb "
                "looks to me like '%2', but then the brackets don't "
                "match in what I have left: '%3'.");
        issue_problem_end();
        return;
    }
```

This code is used in §6.

Subject and Object 8/sob

Purpose

To keep track of the implicit subject and object in assertion sentences, for use in understanding words like "it" and "here" in subsequent sentences.

Definitions

¶1. To define the terms of reference for this chapter, an "assertion" is a sentence such as

> In the middle drawer is a sugared almond.

An "inference" is a basic fact deduced from such a sentence. The above sentence generates three:

O82⟨middle drawer⟩ - `CONTAINSTHINGS_INF` - Certain - 1:O84⟨sugared almond⟩

O84⟨sugared almond⟩ - `PARENTAGE_INF` - Certain - 1:O82⟨middle drawer⟩

O84⟨sugared almond⟩ - `ISAROOM_INF` - Impossible

---

§**1.** "It" and "here", and implicit forms of them such as statements which omit to specify the object they apply to, are surprisingly difficult to parse. Consider:

> The Pavilion is a room. East is the Cricket Square.

East of where? Clearly of the current subject, the Pavilion (*not* the room kind). On the other hand,

> On the desk is a pencil. It has description "2B."

"It" here is the pencil, not the desk. To disentangle such things, we keep track of two different running references: the current subject and the current object. English is an SVO language, so that in assertions of the form "X is Y", X is the subject and Y the object. But it will turn out to be more complicated than that, because we disregard all references which are not to tangible things and kinds.

§**2.** The routine `new_discussion` is called when we reach a heading or other barrier in the source text, to make clear that there has been a change of the topic discussed. `change_discussion_topic` is the only place where the subject and object are changed: it is called once at the end of processing each assertion during each pass.

```
world_object *object_of_sentences, *subject_of_sentences;
int subject_seems_to_be_plural = FALSE;

world_object *get_current_subject(void) {
    return subject_of_sentences;
}

void set_current_subject(world_object *wo) {
    subject_of_sentences = wo;
}

sentence_handler HEADING_SH_handler =
    { HEADING_NT, -1, 0, handle_heading };

void handle_heading(parse_node *PN) {
    new_discussion();
}

void new_discussion(void) {
    subject_of_sentences = NULL; object_of_sentences = NULL;
```

```
}
void change_discussion_topic(world_object *ox, world_object *oy) {
    world_object *old_sub = subject_of_sentences,
        *old_obj = object_of_sentences;
    subject_seems_to_be_plural = FALSE;
    if (current_sentence->word_ref2 - current_sentence->word_ref1 > 0)
        near_start_of_extension = 0;
    pn_set_interpretation_of_subject(current_sentence, subject_of_sentences);
    if (pn_has_annotation(current_sentence, implicit_in_creation_of_ANNOT))
        return;
    if (is_a_direction_object(ox)) ox = NULL;
    if (ox != NULL) subject_of_sentences = ox;
    if ((oy != NULL) && (oy->kind_flag == FALSE)) object_of_sentences = oy;
    else {
        if (ox != NULL) object_of_sentences = ox;
    }
    if (subject_of_sentences != old_sub)
        LOGIF(PRONOUNS, "[Changed subject of sentences to $O]\n",
            subject_of_sentences);
    if (object_of_sentences != old_obj)
        LOGIF(PRONOUNS, "[Changed object of sentences to $O]\n",
            object_of_sentences);
}
void subject_of_discussion_a_list(void) {
    subject_seems_to_be_plural = TRUE;
}
```

The function get_current_subject is called from 6/asp and 8/mass.
The function set_current_subject is called from 8/mass.
The function new_discussion is called from 4/iext and 8/tass.
The function change_discussion_topic is called from 8/mass.
The function subject_of_discussion_a_list is called from 8/mass.

§**3.** The "appearance" is not a property as such. When a quoted piece of text is given without explanation, NI takes it to be either a `description` (in the case of a room) or an `initial` (otherwise). Unfortunately we have no means of knowing yet whether an object is to be a room. We therefore record the text in a special pseudo-property called the "appearance". This will ultimately lead to inferences being drawn about genuine properties in the orthodox way, but not yet.

```
void set_appearance(int w) {
    world_object *wo = get_current_subject();
    specification *spec;
    if (near_start_of_extension >= 1) {
        extension_file *ef = NULL;
        if (lw_array[w].lw_source.file_of_origin)
            ef = sf_get_extension_corresponding(lw_array[w].lw_source.file_of_origin);
        if (ef) {
            dequote_word(w);
            switch (near_start_of_extension++) {
                case 1: ef_set_rubric(ef, lw_array[w].lw_text); break;
                case 2: ef_set_extra_credit(ef, lw_array[w].lw_text);
                    near_start_of_extension = 0; break;
            }
```

```
        }
        return;
    }
    spec = new_actual_CONSTANT_spec(is_a_literal(w, w));
    spec->word_ref1 = w; spec->word_ref2 = w;
    if (wo == NULL) {
        sentence_problem(_P_(C8TextWithoutSubject),
            "I'm not sure what you're referring to",
            "that is, I can't decide to what room or thing you intend "
            "that text to belong. Perhaps you could rephrase this more "
            "explicitly? ('The description of the Inner Sanctum is...')");
        return;
    }
    if (wo->quoted_appearance != NULL) {
        parse_node *P1, *P2;
        P1 = new_nounphrase_raw(wo->quoted_appearance->word_ref1,
            wo->quoted_appearance->word_ref1);
        P2 = new_nounphrase_raw(w, w);
        contradiction_problem(_P_(C8TwoAppearances),
            P1, P2, wo,
            "seems to have two different descriptions",
            "perhaps because you intended the second description "
            "to apply to something mentioned in between, but "
            "declared it in such a way that it was never the "
            "subject of an assertion. For instance, 'The Forest "
            "Clearing is northeast of the Woods.' makes the Forest "
            "Clearing the current room being discussed, but "
            "'Northeast of the Woods is the Forest Clearing.' "
            "leaves the room under discussion unchanged, because "
            "the Forest Clearing is not the subject of the sentence.");
        return;
    }
    wo->quoted_appearance = spec;
    wo->quoted_appearance_sentence = current_sentence;
}
```

The function set_appearance is called from 8/tass.

Refine Parse Tree 8/refpt

Purpose

To determine which world objects are referred to by noun phrases such as “the table” and “a paper cup” found in assertion sentences being parsed.

8/refpt.§16 And surgery; §17 With surgery; §18 Location surgery

§**1.**

```
void resolve_references(parse_node *p) {
    if (p == NULL) internal_error("Resolve references on null pn");
    refine_parse_tree(p, FORBID_CREATION);
}
```

The function resolve_references is called from 6/treec and 9/pp.

§**2.** Resolution of assertions is what happens when an assertion like “On the table is a paper cup” is being read, during the first pass. The noun phrases “the table” and “a paper cup” need to be parsed to see if they refer to things already known to NI, and suitable objects must be created if not.

What happens is that the parse tree structures representing the nouns in any such sentence are “resolved”, using the routine below, which annotates the parse tree with object (and other value) references as necessary.

The flag `permit_creation` can have three values: `FALSE`, which forbids us from creating an object that the text can represent; `TRUE`, which allows us to; or the following special value which positively obliges us to (except in the one special case of the noun phrase “it”):

```
define FORBID_CREATION 0
define ALLOW_CREATION 1
define MANDATE_CREATION 2

int forbid_nowhere = FALSE;
void refine_parse_tree(parse_node *p, int permit_creation) {
    if (p == NULL) internal_error("Refine parse tree on null pn");
    if (pn_int_annotation(p, resolved_ANNOT)) return;
    pn_annotate_int(p, resolved_ANNOT, TRUE);
    LOGIF(NP_RESOLUTION, "Refine parse tree (%s permit creation):\n$T",
        (permit_creation?"do":"do not"), p);
    switch(pn_get_node_type(p)) {
        case X_OF_Y_NT:
            refine_parse_tree(p->down, permit_creation);
            refine_parse_tree(p->down->next, FORBID_CREATION);
            return;
        case WITH_NT:
            refine_parse_tree(p->down, permit_creation);
            perform_with_surgery(p);
            perform_with_action_surgery(p);
            if (pn_int_annotation(p, resolved_ANNOT) == FALSE) {
                refine_parse_tree(p, permit_creation);
                return;
```

```
            }
            return;
        case AND_NT:
            refine_parse_tree(p->down, permit_creation);
            refine_parse_tree(p->down->next, permit_creation);
            perform_and_surgery(p);
            return;
        case RELATIONSHIP_NT:
            perform_location_surgery(p);
            if (pn_get_node_type(p) == AND_NT) {
                pn_annotate_int(p, resolved_ANNOT, FALSE);
                refine_parse_tree(p, permit_creation);
                return;
            }
            ⟨RR - Resolve RELATIONSHIP nodes 4⟩; return;
        case CALLED_NT: ⟨RR - Resolve CALLED nodes 3⟩; return;
        case KIND_NT: ⟨RR - Resolve KIND nodes 5⟩; return;
        case NOUNPHRASE_NT: ⟨RR - Resolve NOUNPHRASE nodes 6⟩; return;
    }
}
```

The function refine_parse_tree is called from 8/creat.

§**3.** A `CALLED_NT` node has two children: in the phrase "an X called Y", they will represent X and Y respectively. Y must be created afresh whatever its name, since the whole point of "called" is that it enables the designer to use names which would otherwise be interpreted as meaning something significant: it is a sort of literal escape, like the backslash character in C strings. X is never something new: it is expected to be a kind. We convert the whole node into a simple `NOUNPHRASE_NT` with the name of Y and the kind of X. In this way, all `CALLED_NT` nodes are removed from the tree.

⟨RR - Resolve CALLED nodes 3⟩ ≡

```
    LOGIF(NP_RESOLUTION, "Called_NT node:\n$T", p);
    switch(pn_get_node_type(p->down)) {
        case RELATIONSHIP_NT: {
                LOGIF(NP_RESOLUTION, "Called_NT as relationship:\n$T", p);
            parse_node *x_pn = p->down->down->next;
            parse_node *name_pn = p->down->next;
            pn_set_node_type(p, RELATIONSHIP_NT);
            pn_annotate_int(p, relationship_node_type_ANNOT,
                pn_int_annotation(p->down, relationship_node_type_ANNOT));
            pn_set_node_type(p->down, CALLED_NT);
            p->down->next = x_pn;
            p->down->down->next = name_pn;
            pn_annotate_int(p, resolved_ANNOT, FALSE);
            refine_parse_tree(p, permit_creation);
            return;
        }
    }
    refine_parse_tree(p->down, FORBID_CREATION);
    if (pn_int_annotation(p->down, nounphrase_multiplicity_ANNOT) > 1) {
        sentence_problem(_P_(C8MultipleCalled),
            "I can only make a single 'called' thing at a time",
            "or rather, the 'called' is only allowed to apply to one thing "
```

```
            "at a time. For instance, 'A thing called a vodka and tonic is "
            "on the table.' is allowed, but 'Two things called vodka and tonic' "
            "is not.");
    }
    forbid_nowhere = TRUE;
    if (permit_creation == FORBID_CREATION)
        sentence_problem(_P_(BelievedImpossible),
            "'called' can't be used in this context",
            "and is best reserved for full sentences.");
    else refine_parse_tree(p->down->next, MANDATE_CREATION);
    forbid_nowhere = FALSE;
    LOGIF(NP_RESOLUTION, "Non-location called:\n$T", p);
    LOGIF(NP_RESOLUTION, "Becomes:\n$T\n - - -\n", p);
```

This code is used in §2.

§**4.** A `RELATIONSHIP_NT` node may have no children, and if so it represents "here". Otherwise we resolve its children, allowing creations: thus "a green marble in a blue box" may cause both marble and box to be created as new.

⟨RR - Resolve RELATIONSHIP nodes 4⟩ ≡ {

```
    binary_predicate *bp;
    if (p->down == NULL) return;
    refine_parse_tree(p->down, permit_creation);
    bp = pn_get_relationship(p);
    if (bp) {
        world_object *dir = bp_get_mapping_direction(bp_get_reversal(bp));
        if (dir) {
            LOGIF(NP_RESOLUTION, "Directional predicate with BP %s ($O, $O)\n",
                bp_get_log_name(bp), bp_get_mapping_direction(bp), dir);
            pn_annotate_int(p, relationship_node_type_ANNOT, DIRECTION_RELN);
            p->down->next =
                new_nounphrase_raw(dir->word_ref1, dir->word_ref2);
            pn_set_node_type(p->down->next, NOUNPHRASE_NT);
            pn_set_refers_to(p->down->next, dir);
        }
    }
    if (p->down->next != NULL) refine_parse_tree(p->down->next, permit_creation);
}
```

This code is used in §2.

§**5.** A `KIND_NT` node may have no children, and if so it represents the bare word "kind": the reference must be to the kind "kind" itself. Otherwise it has one child. Usually this will be the name of an object, e.g. "container", as in "a kind of container", but it might be something like the name of a type, as in "a kind of number".

If this code completes without error, then any `KIND_NT` node `p` either (a) means the kind object held in `pn_get_refers_to(p)`, or (b) has `pn_get_refers_to(p)` null and means "kind of value".

⟨RR - Resolve KIND nodes 5⟩ ≡

```
if (p->down == NULL) { pn_set_refers_to(p, kind_kind); return; }
refine_parse_tree(p->down, FORBID_CREATION);
pn_set_refers_to(p, pn_get_refers_to(p->down));
if (pn_get_refers_to(p) == NULL) {
    if (pn_get_node_type(p->down) != VALUE_NT) goto UnrecognisedKind;
    if (spec_is_generic_CONSTANT(pn_get_evaluation(p->down))) {
        kind_of_value *kov = spec_get_kind_of_value(pn_get_evaluation(p->down));
        if (is_kova(kov, OBJECT_TY)) {
            kind_of_object_problem(_P_(C8KindOfObject));
            return;
        }
        if (is_kova(kov, ANY_VALUE_TY))
            return;
        LOG("$X", pn_get_evaluation(p->down));
        sentence_problem(_P_(C8KindOfExotica),
            "you are only allowed to create kinds of objects "
            "(things, rooms, and so on) and kinds of 'value'",
            "so for example 'colour is a kind of value' is "
            "allowed but 'prime is a kind of number' is not.");
        break;
        return;
    }
    if (spec_is_UNKNOWN(pn_get_evaluation(p->down))) {
        UnrecognisedKind:
        LOG("p-tree:\n$T", p);
        sentence_problem(_P_(C8NoSuchKind),
            "I don't recognise that as a kind",
            "such as 'room' or 'door'.");
        return;
    }
    sentence_problem(_P_(C8KindOfActualValue),
        "I don't recognise that as a kind",
        "such as 'room' or 'door': it would need to be "
        "straightforwardly the name of a kind, and not "
        "be qualified with adjectives like 'open'.");
    return;
} else {
    if (pn_get_refers_to(p)->kind_flag == FALSE) {
        sentence_problem(_P_(C8KindOfInstance),
            "kinds can only be made from other kinds",
            "so 'a kind of container' is allowed but 'a kind of "
            "Mona Lisa' (where Mona Lisa is a specific thing "
            "you've already made), wouldn't be allowed. There is "
            "only one Mona Lisa.");
```

```
            return;
        }
    }
```

This code is used in §2.

§**6.** The simple description of what happens to a `NOUNPHRASE_NT` node is that if it's an existing object, then `refers` is set to that; and if not, a new object of that name is created, and `refers` set to the new thing. But "it" is an exception and we also look out for action patterns, property names and values like "121" or "number of turns". And if `permit_creation` is `FALSE`, then we give up and set the `refers` to null rather than create something new. This is important for cases where the noun phrase is known to be not an object – for instance, for the Y in "an X with Y", which is expected to be a property list. The more complicated description is as follows:

⟨RR - Resolve NOUNPHRASE nodes 6⟩ ≡

```
    if ((p->word_ref1 == -2) && (p->word_ref1 == -2)) {
        pn_make_player_noun_phrase(p);
        return;
    }
    ⟨RRN - Resolve new-property of 7⟩;
    ⟨RRN - Resolve IT 8⟩;
    if ([[p == nowhere]] &&
        (unexpectedly_upper_case(p->word_ref1) == FALSE) &&
        (forbid_nowhere == FALSE)) {
        pn_set_refers_to(p, NULL);
        return;
    }
    if (permit_creation != MANDATE_CREATION) {
        if [[p == description]] {
            ⟨RRN - Resolve property names 13⟩;
        } else {
            ⟨RRN - Resolve values 9⟩;
            ⟨RRN - Resolve property names 13⟩;
        }
        ⟨RRN - Resolve action patterns 14⟩;
    }
    Unresolved:
    LOGIF(NP_RESOLUTION, "Unresolved\n");
    if (permit_creation) pn_set_node_type(p, CREATED_NT);
    else pn_set_refers_to(p, NULL);
```

This code is used in §2.

§**7.** The following is needed to handle something like "colour of the box", where "colour" is a newly designed type which has coincided with a property, but which was not known to be a property when the parse tree was grown.

⟨RRN - Resolve new-property of 7⟩ ≡ {

```
    int i = is_word_intermediate(of_V, p->word_ref1, p->word_ref2);
    if (i >= 0) {
        property_name *prn = parse_property_name(p->word_ref1, i-1);
        if (prn) {
            if (prn_coincides_with_kind_of_value(prn)) {
                LOGIF(NP_RESOLUTION, "Resolving new-property of: $Y\n", prn);
                pn_set_node_type(p, X_OF_Y_NT);
                p->down = new_nounphrase_articled(i+1, p->word_ref2);
                p->down->next = new_nounphrase_worldly(p->word_ref1, i-1, FALSE);
                pn_annotate_int(p, resolved_ANNOT, FALSE);
                LOGIF(NP_RESOLUTION, "Resolved new-property to:\n$T\n", p);
                refine_parse_tree(p, permit_creation);
                return;
            }
        }
    }
}
```

This code is used in §6.

§**8.** A noun phrase consisting of a pronoun has `refers` set to the relevant thing. (If we had more and better pronouns, they would go here.)

⟨RRN - Resolve IT 8⟩ ≡

```
    if (pn_int_annotation(p, nounphrase_article_ANNOT) == IT_ART) {
        if ([[p == they]] && (subject_seems_to_be_plural)) {
            sentence_problem(_P_(C8EnigmaticThey),
                "I'm unable to handle 'they' here",
                "since it looks as if it needs to refer to more than one "
                "object here, and that's something I can't manage.");
            return;
        }
        if (object_of_sentences == NULL) {
            sentence_problem(_P_(C8EnigmaticPronoun),
                "I'm not sure what to make of the pronoun here",
                "since it is unclear what previously mentioned thing "
                "is being referred to. In general, it's best only to use "
                "'it' where it's unambiguous, and it may be worth noting "
                "that 'they' is not allowed to stand for more than one "
                "object at a time.");
            return;
        }
        pn_set_refers_to(p, object_of_sentences);
        LOGIF(PRONOUNS, "Interpreting 'it' as $O\n$P", object_of_sentences, current_sentence);
        return;
    }
```

This code is used in §6.

§**9.** The hard parsing is left to the routine `parse_expression`, which converts textual matter into a specification. It can return a number of type IDs other than the ones checked below, and indeed can return other forms of the type `DESCRIPTION_SPC`: but these other forms are never valid in an assertion, so we need not worry about them here.

⟨RRN - Resolve values 9⟩ ≡

```

        if (and_needed && (i < n)) {
            p2->next = new_node(AND_NT);
            p2->next->down = p3;
            and_needed = FALSE;
        } else { p2->next = p3; and_needed = TRUE; }
        p2 = p3;
    }
    return TRUE;
}
```

The function grow_as_NP_with_adjectives is called from 8/assem.

§**16. And surgery.** "And surgery" is a fiddly operation to correct the parse tree after resolution of all the nouns in a phrase which involves both "and" and "with" in a particular way. There's no problem with either of these:

> In the Pitch are a bat and ball with score for finding 10. In the Pitch is a sweater with score for finding 5 and description "White wool."

neither of which is altered by and surgery. The difficulty arises with

> In the Pitch is an openable and open door with description "The Hut door."

which, we notice, has exactly the same grammatical structure as the first of the two sentences above, yet a very different meaning, since "openable" is a property whereas "bat" was an object. We perform surgery on:

```
AND_NT
    ADJECTIVE_NT prop:p46_openable
    WITH_NT
        INSTANCE_NT K4_door
        ADJECTIVE_NT prop:p44_open
```

to restructure the nodes as:

```
WITH_NT
    INSTANCE_NT K4_door
    AND_NT
        ADJECTIVE_NT prop:p46_openable
        ADJECTIVE_NT prop:p44_open
```

This innocent-looking little routine involved drawing a *lot* of diagrams on the back of an envelope. Change at your peril.

```
void perform_and_surgery(parse_node *p) {
    parse_node *x, *a_p, *w_p, *p1_p, *p2_p, *i_p;
    if ((pn_get_node_type(p->down) == ADJECTIVE_NT)
        && (pn_get_node_type(p->down->next) == WITH_NT)) {
        a_p = p; p1_p = p->down; w_p = p->down->next;
        i_p = w_p->down; p2_p = i_p->next;
        pn_set_node_type(a_p, WITH_NT);
        pn_set_node_type(w_p, AND_NT);
        pn_set_refers_to(a_p, pn_get_refers_to(w_p));
        pn_set_refers_to(w_p, NULL);
        x = a_p; a_p = w_p; w_p = x;
        w_p->down = i_p;
```

```
        i_p->next = a_p;
        a_p->down = p1_p;
        a_p->down->next = p2_p;
    }
}
```

§**17. With surgery.** This is a less traumatic operation, motivated by sentences like:

> In the Pitch is an open container with description "The box of stumps and bails."

The initial parse tree for such a sentence will have two nested `WITH_NT` clauses, which is arguably correct – "a (container with property open) with description ..." – but which is inconvenient for our implementation of `WITH_NT` later on. So we construe the sentence instead with a single "with", as "a container with properties open and description ..." In terms of the tree,

```
    WITH_NT
        WITH_NT
            INSTANCE_NT K4_container
            ADJECTIVE_NT prop:p44_open
        PROPERTYLIST_NT "The box..."
```

is reconstructed as:

```
    WITH_NT
        INSTANCE_NT K4_container
        AND_NT
            ADJECTIVE_NT prop:p44_open
            PROPERTYLIST_NT "The box..."
```

```
void perform_with_surgery(parse_node *p) {
    parse_node *inst, *prop_1, *prop_2;
    if ((pn_get_node_type(p) == WITH_NT) && (pn_get_node_type(p->down) == WITH_NT)) {
        inst = p->down->down;
        prop_1 = p->down->down->next;
        prop_2 = p->down->next;
        p->down = inst;
        p->down->next = new_node(AND_NT);
        p->down->next->down = prop_1;
        p->down->next->down->next = prop_2;
    }
}
void perform_with_action_surgery(parse_node *p) {
    if (pn_get_node_type(p) == WITH_NT) {
        int a1 = p->down->word_ref1, a2 = p->down->next->word_ref2;
        if ((a1>=0) && (a2>=a1)) {
            action_pattern ap = parse_action_pattern(a1, a2, IS_TENSE);
            if (ap_is_valid(&ap)) {
                pn_set_node_type(p, ACTION_NT);
                p->word_ref1 = a1; p->word_ref2 = a2; p->down = NULL;
            }
        }
    }
}
```

§**18. Location surgery.** This is needed to make sentences like the second one here work:

> The escalator is a door. It is below the Kudamm and above the U-Bahn.

```
    RELATIONSHIP_NT <below> (CONTAINSTHINGS_INF)
        AND_NT
            NOUNPHRASE_NT <kudamm> (definite)
            RELATIONSHIP_NT <above> (CONTAINSTHINGS_INF)
                NOUNPHRASE_NT <u-bahn> (definite)
```

into:

```
    AND_NT
        RELATIONSHIP_NT <below> (CONTAINSTHINGS_INF)
            NOUNPHRASE_NT <kudamm> (definite)
        RELATIONSHIP_NT <above> (CONTAINSTHINGS_INF)
            NOUNPHRASE_NT <u-bahn> (definite)
```

```
void perform_location_surgery(parse_node *p) {
    parse_node *old_and, *old_np1, *old_loc2;
    if ((pn_get_node_type(p) == RELATIONSHIP_NT) &&
        (p->down) && (pn_get_node_type(p->down) == AND_NT) &&
        (p->down->down) && (p->down->down->next) &&
        (pn_get_node_type(p->down->down->next) == RELATIONSHIP_NT)) {
        pn_annotate_int(p, resolved_ANNOT, FALSE);          otherwise this will be wrongly copied
        old_and = p->down;
        old_np1 = old_and->down;
        old_loc2 = old_and->down->next;
        pn_copy(old_and, p);                                making this the new first location node
        pn_set_node_type(p, AND_NT);                                          and this is new AND
        p->down = old_and;
        old_and->down = old_np1;
        old_and->next = old_loc2;
        old_np1->next = NULL;
    }
}
```

The Creator 8/creat

Purpose

This is where all objects, kinds of object, and newly named values are made.

8/creat.§9 Instantiation

Template interpreter commands

```
1   {-callv:create_kind_kind}
```

---

§**1.** The following routine is used early on to creates the special kind "kind". There are other kinds which need to exist for NI to work, but those will all be created in the Standard Rules: "kind" cannot be created that way because there is nothing for it to be a kind of.

Note that the kind "kind" has no name. This is because we needed the word to be a reserved word, so to speak, when resolving assertions: and we would not want people to create "a kind of kind", and such.

```
void create_kind_kind(void) {
    pcalc_prop *prop = prop_to_create_something(kova(OBJECT_TY), -1, -1);
    prop = prop_concatenate(prop, prop_to_make_a_kind());
    prop_true_in_world_model(prop);
}
```

The function create_kind_kind is invoked by a command in a `.i6t` template file.

§**2.**

```
int problem_count_when_creator_started;
int make_necessary_creations(parse_node *px, parse_node *py) {
    problem_count_when_creator_started = problem_count;
    if [[px == there]] {
        int i, np1, np2, rp1, rp2;
        if [[py == ... in ... : i --> np1, np2 ... rp1, rp2]] {
            if [[i, rp2 == which is/are ...]] rp1++;
            rp1--;
            px->word_ref1 = np1; px->word_ref2 = np2;
            py->word_ref1 = rp1; py->word_ref2 = rp2;
            make_assertion(px, py);
            return FALSE;
        }
        refine_parse_tree(py, ALLOW_CREATION); noun_creator(py, NULL, NULL);
        if (pn_get_node_type(py) == INSTANCE_NT)
            convert_instance_to_nounphrase(py, 0, FALSE);
        pn_set_node_type(px, NOUNPHRASE_NT);
        pn_set_refers_to(px, pn_get_refers_to(py));
    } else {
        refine_parse_tree(px, ALLOW_CREATION);
        refine_parse_tree(py, ALLOW_CREATION);
        if ((pn_get_node_type(px) == ACTION_NT) &&
```

```
            (pn_get_node_type(py) == CREATED_NT)) {
            pn_set_node_type(py, ACTION_NT);
            return TRUE;
        }
        if ((pn_get_node_type(px) == ACTION_NT) &&
            (pn_get_node_type(py) == KIND_NT)) {
            pn_set_node_type(px, CREATED_NT);
        }
        parse_node *govx = NULL, *govy = NULL;
        kind_of_value *kovx = NULL, *kovy = NULL;
        binary_predicate *bp = NULL;
        if (bp == NULL) bp = bp_of_subtree(py);
        if (bp == NULL) bp = bp_of_subtree(px);

§**9. Instantiation.** If there is really such a word. The INSTANCE_NT node sometimes means to talk about things in general, sometimes things in particular: consider the two sentences

A container is usually open. A container is in the Box Room.

At initial parse tree time, and even now at resolution time, we cannot easily differentiate these meanings. We will only be able to do so later, when making assertions. When it turns out that the INSTANCE_NT is to be made into something nameless but tangible, as in the second sentence above, the following routine is used to transform it into a suitable NOUNPHRASE_NT referring to the newly created object.

```
void convert_instance_to_nounphrase(parse_node *p, int assertion_depth,
    int confect_name_flag) {
    int i, ic;
    parse_node *new_subtree = new_node(INSTANCE_NT);

Definitions

¶1. In this section we are concerned with assertions, that is, declarations of the form "X is Y". For etymological reasons, the English verb "to be" is a mixture of several different verbs which have blurred together into one: consider "I am 5", "I am happy" and "I am Chloe". NI compounds the problem by allowing X and Y to be more complicated clauses than simple nouns, and also by distinguishing between the specific ("the lacquered box") and the non-specific ("a container"), and between the tangible ("box" again) and the intangible ("101").

The work of growing the parse tree and resolving its references now enables us to classify assertions into 196 grammatically different forms, which we group into 56 main cases. (The fact that relatively few of these split into sub-cases shows that the parse tree, when resolved at least, encodes meaning surprisingly well.) Of these cases, about half produce valid NI sentences in at least some situations, while the other half lead certainly to problem messages.

The verb "to be" occupies some 12 columns of the *Oxford English Dictionary* and they make useful reading in clarifying the problem. For instance, NI's distinction between spatial and property knowledge reflects the OED's distinction between meanings 5a and 9b respectively. NI's assertion cases construe the verb "to be" as follows:

(a) Cases 6, 7 and 8 are forms of "to have" in disguise as "to be allowed to have".
(b) Cases 10, 11, 13, 22 and 25 to 29 are "to be" with OED meaning 10, "to exist as the thing known by a certain name; to be identical with".
(c) Cases 15 to 21, 48 and 49 are "to be" with OED meaning 5a, "to have or occupy a place somewhere".
(d) Cases 43 to 47 are ungrammatical as "to be", and are in fact "to have": they are given here because common code is used to implement both verbs, which reflects the curious way that English "to be" has subsumed much of the function that "to have" serves in other languages.
(e) And all other cases are "to be" with OED meaning 9b, "to have a place among the things distinguished by a specified quality".

---

§**1.** Here is the main routine which asserts that subtree `px` "is" `py`. Note that references are "resolved" only on the first of the two passes through: making one assertion may change the way that the next one is resolved, so we cannot simply resolve the whole parse tree before making assertions.

```
void make_assertion(parse_node *px, parse_node *py) {
    if (traverse == 1) if (make_necessary_creations(px, py) == FALSE) return;
```

```
    if (trace_sentences) log_subtree(current_sentence, 1);
    if (![[px == there]]) make_assertion_recursive(px, py, 0);
    change_discussion_topic(pn_get_refers_to(px), pn_get_refers_to(py));
    if (pn_get_node_type(px) == AND_NT) subject_of_discussion_a_list();
}
```

The function make_assertion is called from 8/creat and 10/tab.

§**2. The Assertion Matrix.** The essential meaning of the assertion is reflected in the structure of `px` and `py`, which in turn is most easily distinguished by their node types. We want to be sure that we completely understand this process and that no possibilities escape notice. We therefore use a 14×14 matrix of possible cases, as follows. The cases are numbered from 1 to 57 inclusive and there is no significance to their ordering. Mathematically enough, `py` specifies the row and `px` the column.

define ASSERTION_MATRIX_DIM 14

```
typedef struct matrix_entry {
    int row_node_type;
    int cases[ASSERTION_MATRIX_DIM];
} matrix_entry;
matrix_entry assertion_matrix[ASSERTION_MATRIX_DIM] = {
                  W, A, A, A, A, K, I, L, N, P, P, V, X, E
{ WITH_NT,         {  3,  1,  1,  1,  1,  1,  1, 48,  1,  1,  1,  1,  1, 51 } },
{ AND_NT,          {  2,  4,  4,  4,  4,  4,  4,  4,  4,  4,  4,  4,  4, 51 } },
{ ACTION_NT,       {  2,  5, 30, 33,  6, 33, 24, 21, 34, 33, 33, 57, 28, 51 } },
{ ADJECTIVE_NT,    {  2,  5, 32, 42,  6, 35, 36, 21, 36, 39, 39, 36, 54, 51 } },
{ ALLOWED_NT,      {  2,  5,  7,  7,  6,  7,  8,  7,  8,  7,  7,  7,  7,  8 } },
{ KIND_NT,         {  2,  5, 12, 12,  6, 12, 12, 12, 12, 12, 12, 12, 12, 51 } },
{ INSTANCE_NT,     {  2,  5, 24, 24,  6, 24, 16, 15, 14, 46, 24, 24, 24, 51 } },
{ RELATIONSHIP_NT, { 49,  5, 21, 21,  6, 21, 17, 18, 19, 21, 21, 56, 27, 53 } },
{ NOUNPHRASE_NT,   {  2,  5, 31, 38,  6, 35, 23, 20, 22, 44, 13, 10, 29, 51 } },
{ PROPERTYLIST_NT, {  2,  5, 33, 39,  6, 35, 45, 21, 43, 40, 40, 47, 28, 51 } },
{ PROPERTYNOUN_NT, {  2,  5, 32, 39,  6, 35, 24, 21, 37, 40, 40, 37, 28, 51 } },
{ VALUE_NT,        {  2,  5, 33, 41,  6, 35, 24, 55,  9, 47, 13, 11, 29, 51 } },
{ X_OF_Y_NT,       {  2,  5, 26, 26,  6, 26, 24, 21, 26, 26, 26, 26, 25, 51 } },
{ EVERY_NT,        { 50, 50, 50, 50, 50, 50, 50, 50, 50, 50, 50, 50, 50, 52 } } };
```

The structure matrix_entry is private to this section.

§**3.** The following routine simply looks up which of the 56 cases the current pair of `px` and `py` falls into.

```
int which_assertion_case(parse_node *px, parse_node *py) {
    int i, x=-1, y=-1;
    if (px == NULL) internal_error("make assertion with px NULL");
    if (py == NULL) internal_error("make assertion with py NULL");
    if (pnt_allow_in_assertions(px) == FALSE) {
        log_subtree(px, 1);
        internal_error("make assertion with improper px node");
    }
    if (pnt_allow_in_assertions(py) == FALSE) {
        log_subtree(py, 1);
        internal_error("make assertion with improper py node");
    }
    for (i=0; i<ASSERTION_MATRIX_DIM; i++)
        if (assertion_matrix[i].row_node_type == pn_get_node_type(px)) x=i;
    for (i=0; i<ASSERTION_MATRIX_DIM; i++)
        if (assertion_matrix[i].row_node_type == pn_get_node_type(py)) y=i;
    if (x<0) {
        log_subtree(px, 1);
        internal_error("make assertion with px node not in matrix");
    }
    if (y<0) {
        log_subtree(py, 1);
        internal_error("make assertion with py node not in matrix");
    }
    return assertion_matrix[y].cases[x];
}
```

§**4. Splitting into cases.** The point of the matrix is to prove the following:

Proposition. *Every assertion either (a) adds to our knowledge of the model world (on at least one of the two passes) or (b) results in a problem message being issued (on at least one of the two passes).*

This may sound trivial to arrange, but the experience of the previous two drafts of the assertion maker showed that it was all too easy for certain assertions to fall through a net of comparisons and thus be ignored altogether. On each pass, each assertion is processed with exactly one of the cases and nothing else is done with it, except for one general rule: a requirement that we can only talk about specific things in definite terms. This is enforced by reference to the `prevailing_mood`, the level of certainty which the source text expressed about the assertion being made. (For instance, "A door is usually open" is a less certain assertion than "The black door is open".)

```
void make_assertion_recursive(parse_node *px, parse_node *py,
    int assertion_depth) {
    STREAM_INDENT(dl);
    make_assertion_recursive_inner(px, py, assertion_depth);
    STREAM_OUTDENT(dl);
}

void make_assertion_recursive_inner(parse_node *px, parse_node *py,
    int assertion_depth) {
    int ma_case;
    assertion_depth++;
```

```
    ma_case = which_assertion_case(px, py);
    LOGIF(ASSERTIONS, "[$W/$N] =%d [$W/$N]\n",
        px->word_ref1, px->word_ref2, pn_get_node_type(px), ma_case,
        py->word_ref1, py->word_ref2, pn_get_node_type(py));
    if (traverse == 2) {
        if ((prevailing_mood != UNKNOWN_CE) && (pn_get_refers_to(px) != NULL) &&
            (pn_get_refers_to(px)->kind_flag == FALSE)) {
            sentence_problem(_P_(C8VagueAboutSpecific),
                "you can only equivocate with 'usually', 'rarely', "
                "'always' and the like when talking about kinds of thing",
                "because when a specific thing is involved you should say "
                "definitely one way or another. 'A cave is usually dark' is "
                "fine, but not 'the Mystic Wood is usually dark'.");
            return;
        }
    }
    if (traverse == 2) {
        if (((pn_get_node_type(px) == INSTANCE_NT)
            && (pn_get_evaluation(px)) && (spec_get_quantification_parameter(pn_get_evaluation(px))
> 1)
            && (pn_get_node_type(py) != RELATIONSHIP_NT)) ||
            ((pn_get_node_type(py) == INSTANCE_NT)

            internal_error("No implementation for make assertion case");
    }
}
```

The function make_assertion_recursive is called from 8/creat.

§**5. Case 1.** "A is a B with I": process as "A is a B" followed by "A is I", which works nicely because we bend grammar to allow "is" in place of "has" when it comes to lists of property values. This construction is only meaningful for a few possible node types of A, but we don't provide any special problem messages for the rest, because recursion will do the job for us. But see also case 48.

The wickerwork box is a container with description "Pricy." The bat and ball are things with description "Cricket equipment." A trophy is a kind of container with score for finding 5.

⟨MA1 - Y is WITH 5⟩ ≡
```
make_assertion_recursive(px, py->down, assertion_depth);
if ((pn_get_node_type(px) == NOUNPHRASE_NT) &&
    (is_a_direction_object(pn_get_refers_to(px))) &&
    (pn_get_node_type(py->down) == NOUNPHRASE_NT))
make_assertion_recursive(py->down, py->down->next, assertion_depth);
else
make_assertion_recursive(px, py->down->next, assertion_depth);
```

This code is used in §4.

§**6. Case 2.** "An A with I is B": we treat this symmetrically with case 1, but only in order that the assertions we recurse into will produce a suitable problem message: so this does not really do anything constructive. It *is* possible for a left-hand WITH to do something meaningful, but only when a location is on the right, which is case 49, or when we have an implication.

A container with description "Solid." is the solid box.

⟨MA2 - X is WITH 6⟩ ≡
```
if ((pn_get_node_type(px->down) == INSTANCE_NT) &&
    (is_adjlist(px->down->next)) &&
    (is_adjlist(py))) {
    imp_new(px, py);
} else {
    int np = problem_count;
    make_assertion_recursive(px->down, py, assertion_depth);
    if (problem_count == np)
        make_assertion_recursive(px->down->next, py, assertion_depth);
}
```

This code is used in §4.

§**7. Case 3.** "A with B is C with D" must be incorrect.

A container with description "White" is a container with description "Black".

⟨MA3 - X and Y are WITH - P 7⟩ ≡
```
assertion_problem(_P_(C8Case3),
    "you can't say that one general description is another ",
    "for instance by writing 'A container with carrying capacity 10 "
    "is a dark room'.");
```

This code is used in §4.

§**8. Case 4.** "A is B and C": process as "A is B" then "A is C".

⟨MA4 - Y is AND 8⟩ ≡
```
{ parse_node *across = py->down;
    while (across) {
        make_assertion_recursive(px, across, assertion_depth);
        across = across->next;
    }
}
```

This code is used in §4.

§**9. Case 5.** "A and B are C": process as "A is C" then "B is C".

⟨MA5 - X is AND 9⟩ ≡
```
    parse_node *across = px->down;
    int np = problem_count;
    while (across) {
        if (np == problem_count)
            make_assertion_recursive(across, py, assertion_depth);
        across = across->next;
    }
```

This code is used in §4.

§**10. Case 6.** This can be proved never to happen, but just in case:

⟨MA6 - X is ALLOWED - P 10⟩ ≡
```
    internal_error("Forbidden case 6 in make assertion has occurred.");
```

This code is used in §4.

§**11. Case 7.** Permission granted for a property, where A is not an object.

A number has a number called square root.

⟨MA7 - Y is ALLOWED - P 11⟩ ≡
```
    if [[px == player]] {

                        "it is indeed a rulebook when we give it named values",
                        "to reduce the risk of ambiguity. So 'The every turn rulebook has a "
                        "number called the accumulated bonus' is fine, but 'Every turn has a "
                        "number called...' is not. (I'm insisting on the presence of the word "
                        "'rulebook' because the syntax is so close to that for giving "
                        "properties to objects, and it's important to avoid mistakes here.)");
                        }
                        return;
                    }
                }
            }
            assertion_problem(_P_(C8Case7),
                "only an object, kind, rulebook, action or activity can be allowed to "
                "have properties or variables",
                "so for instance 'A door has a colour' is fine but "
                "'A number has a length' is not.");
```

This code is used in §4.

§12. Case 8. This time a valid permission.

A container has a number called security rating.

⟨MA8 - X is NOUNPHRASE or INSTANCE, Y is ALLOWED 12⟩ ≡

```
    if (traverse == 1) recursively_declare_properties(px, py->down);
```

This code is used in §4.

§**13. Case 9.** Two sorts of sentence can validly fall under this heading. The first is easy:

The innings total is a number that varies.

But the second takes some setting up. Only the last of these sentences falls into case 9:

Colour is a kind of value. Green and blue are colours. A thing has a colour. The barn door is green.

⟨MA9 - X is NOUNPHRASE, Y is VALUE 13⟩ ≡ {

```
    kind_of_value *kov;
    quantity *q = spec_get_constant_quantity_if_any(pn_get_evaluation(py));
    if (q) {
        property_name *pname = kov_get_coinciding_property(qty_kind_of_value(q));
        if (pname) {
            if (traverse == 2) assert_property_value_from_property_subtree(pname, pn_get_refers_to(px),
NULL, py);
            return;
        }
    }
    if (spec_is_generic_CONSTANT(pn_get_evaluation(py))) {
        if (traverse == 1) issue_value_equation_problem(px, py);
        return;
    }
    kov = spec_get_kind_of_value(pn_get_evaluation(py));
    if (kov_name_can_coincide_with_property(kov)) {
        property_name *pname = kov_get_coinciding_property(kov);
        if (pname) {
            if (traverse == 2) assert_property_value_from_property_subtree(pname, pn_get_refers_to(px),
NULL, py);
            return;
        }
    }
    assertion_problem(_P_(C8Case9),
        "this seems to say that a thing is a value",
        "like saying 'the chair is 10'.");
}
```

This code is used in §4.

§14. Case 10. Symmetrically, if questionably, we allow "A number variable is the departures counter". The only examples I can think of are poor style, so perhaps this case should in fact produce a problem.

The other test below, though, is important: it handles setting a variable to a value which happens to be a specifically named object, as in the second of these sentences:

The quest assignment is a thing that varies. The quest assignment is the Holy Grail.

⟨MA10 - X is VALUE, Y is NOUNPHRASE 14⟩ ≡

```
if ((pn_get_refers_to(py) != NULL) &&
    (spec_get_storage_form(pn_get_evaluation(px)) == NONLOCAL_VARIABLE_SPC)) {
    quantity *q = RETRIEVE_FROM_SPEC(pn_get_evaluation(px), quantity);
    if (traverse == 1) return;
    if (q == NULL) internal_error("Null quantity in value");
    if (qty_is_a_variable(q)) {
        kind_of_value *variable_kov = qty_kind_of_value(q);
        kind_of_value *constant_kov;
        specification *initialiser = world_object_to_OBJECT_spec(pn_get_refers_to(py));
        if ((pn_get_refers_to(py)) && (pn_get_refers_to(py)->kind))
            constant_kov = kovko(pn_get_refers_to(py)->kind);

    return;
}
assertion_problem(_P_(C8Case10b),
    "this seems to say that a thing is a value",
    "like saying 'the chair is 10'.");
```

This code is used in §4.

§**15. Case 11.** Usually it makes no sense to equate two values: "5 is 10", for instance, and we produce a variety of more or less scornful errors.

```
10 is 15. 14 is a number. "Fish" is text. The turn count is a text. 19 is a rulebook. "Frog"
is a number. Before rules is a rule. The turn count is "Surprising."
```

But we do take polite notice when X is a variable name and Y is an initial value with a compatible type, as in the second sentence here:

```
The innings total is a number that varies. The innings total is 101.
```

⟨MA11 - X and Y are VALUEs 15⟩ ≡

```

        }
        assert_property_value_from_property_subtree(pn_get_property(px), get_current_subject(),
NULL, py);
    }
```

This code is used in §4.

§**18. Case 14.** We first worry about "East is a dead end", which must not change the kind of the "east" object. But we must be careful not to catch "East is a direction" in the same net because, of course, that does set its kind. We essentially rewrite as:

Z is a dead end. East is Z.

where Z is a newly created and nameless object, but we do not allow the first assertion to change the current subject of conversation, as then the second assertion would say that Z is east of Z, not east of the current room.

But most of the sentences falling into this case have the form "X is a Y." We can test both varieties with the latter two sentences in the following:

The Pitch is a room. East is a room. The lacquered box is a container.

⟨MA14 - X is NOUNPHRASE, Y is INSTANCE 18⟩ ≡

```
    if (pn_get_refers_to(px) == NULL) {

        return;
    }
    if [[py == everywhere]] assert_object_everywhere(pn_get_refers_to(px));
    else assert_instance(px, py);
```

This code is used in §4.

§**19. Case 15.** "On the table is a container." Much the same as case 14a, but the code is duplicated to avoid having to `goto` between cases.

In the desk is a copy of Wisden.

⟨MA15 - X is RELATIONSHIP, Y is INSTANCE 19⟩ ≡

```
if ((px->down) && (pn_get_node_type(px->down) == EVERY_NT)) {
    make_generalisation(px, py);
    return;
}
if (pn_get_refers_to(py) == kind_region) {
    assertion_problem(_P_(C8Case15),
        "a region cannot be given a specific location",
        "since it contains what may be many rooms, which may not be "
        "contiguous and could be scattered about all over. (Sometimes "
        "this problem arises because an ambiguous sentence like 'East "
        "of Eden is a region.' has been used: Inform reads that as "
        "saying that a nameless region lies to the east of the room "
        "'Eden'. The desired effect can be got using 'called' to stop "
        "Inform taking 'East of' literally: for instance, 'The Land of "
        "Nod is in a region called East of Eden.'");
    return;
}
convert_instance_to_nounphrase(py, assertion_depth,
    (pn_get_relationship(px) == a_incorporates_b_predicate));
make_assertion_recursive(px, py, assertion_depth);
```

This code is used in §4.

§**20. Case 16.** This can involve a tautology, or a contradiction in terms:

A room is a room. A container is a door.

But it can also be valid, as in the final sentence here:

Colour is a kind of value. The colours are green and purple. A room has a colour. A room is usually purple.

⟨MA16 - X and Y are INSTANCE - P 20⟩ ≡

```
if (spec_get_proposition(pn_get_evaluation(px)) == NULL) {
    if [[py == everywhere]] assert_object_everywhere(pn_get_refers_to(px));
    assert_instance(px, py);
    return;
}
assertion_problem(_P_(C8Case16),
    "one description cannot equal another",
    "by saying something like 'a container is a room' (not true!) or "
    "even 'a dark room is a room' (true but a tautology, so not allowed "
    "because it suggests that something else was meant instead).");
```

This code is used in §4.

§**21. Case 17.** This is a finicky stylistic error, and it strikes me as quite likely that the beta-testers will object to it.

An animal is in the desk.

⟨MA17 - X is INSTANCE, Y is RELATIONSHIP - P 21⟩ ≡

```
if ((py->down) && (pn_get_node_type(py->down) == EVERY_NT)) {
    make_generalisation(py, px);
    return;
}
if (spec_get_quantification_parameter(pn_get_evaluation(px)) >= 1) {

    make_assertion_recursive(py, px, assertion_depth);
    return;
}
if ((pn_get_relationship(py)) &&
    (bp_sets_a_property(pn_get_relationship(py)))) {
    assert_subtree_in_relationship(px, py);
    return;
}
if ((pn_get_relationship(py)) &&
    (bp_relates_values_not_objects(pn_get_relationship(py)))) {
    assert_subtree_in_relationship(px, py);
    return;
}
assertion_problem(_P_(C8Case17),
    "something described only by its kind should not be given a "
    "specific place or role in the world",
    "to avoid ambiguity. For instance, suppose 'car' is a kind. Then "
    "we are not allowed to say 'a car is in the garage': there's too "
    "much risk of confusion between whether an individual (but "
    "nameless) car is referred to, or whether cars are generically to "
    "be found there. Sentences of this form are therefore prohibited, "
    "though more specific ones like 'a car called Genevieve is in the "
    "garage' are fine, as is the reverse, 'In the garage is a car.'");
```

This code is used in §4.

§**22. Case 18.** The first of these sample sentences is deservedly rejected, but the second makes a non-reciprocal map connection: "D of the R is E of the S" is construed as "D of the R is S" then "R is E of the S". We have to suppress NI's tendency to make tentative reciprocal map connections, because even though they will only be listed as "likely", we know they are in fact impossible in this case.

In the box is on the desk. East of the Pitch is north of the Pavilion.

⟨MA18 - X and Y are RELATIONSHIP 22⟩ ≡

```
if ((pn_int_annotation(px, relationship_node_type_ANNOT) == DIRECTION_RELN) &&
    (pn_int_annotation(py, relationship_node_type_ANNOT) == DIRECTION_RELN)) {
    enter_one_way_mapping_mode();

    "items all at once",
    "which can lead to ambiguities. For instance, 'The description of "
    "an open door is \"It's open.\"' is not allowed: if we followed "
    "Inform's normal conventions strictly, that would be an instruction "
    "to create a new, nameless, open door and give it the description. "
    "But this is very unlikely to be what the writer intended, given "
    "the presence of the adjective to make it seem as if a particular "
    "door is meant. So in fact we reject such sentences unless they "
    "refer only to a kind, without adjectives: 'The description of a "
    "door is \"It's a door.\"' is fine. (If the idea is actually to "
    "make the description change in play, we could write a rule like "
    "'Instead of examining an open door, say \"It's open.\"'; or we "
```

```
        "could set the description of every door to "
        "\"[if open]It's open.[otherwise]It's closed.\".)");
```

This code is used in §4.

§34. Case 30.

⟨MA30 - X and Y are ACTION - P 34⟩ ≡

```
    if (traverse == 2) {
        action_pattern apx, apy;
        apx = parse_action_pattern(px->word_ref1, px->word_ref2, IS_TENSE);
        apy = parse_action_pattern(py->word_ref1, py->word_ref2, IS_TENSE);
        if ((ap_is_valid(&apy)) && (ap_is_named(&apy) == FALSE)) {
            log_action_pattern(&apx);
            log_action_pattern(&apy);
            assertion_problem(_P_(C8Case30),
                "two actions are rather oddly equated here",
                "which would only make sense if the second were a named "
                "pattern of actions like (say) 'unseemly behaviour'.");
            return;
        }
        categorise_action_as(apx, py->word_ref1, py->word_ref2);
    }
```

This code is used in §4.

§35. Case 31. When we need to create a new named action pattern, as in the sentence

Taking something is theft.

when nothing has previously been referred to as "theft", so that it is still being treated as a noun phrase (and presumed to be an object). What we do converts node Y to `ACTION_NT` type, so if it happens on pass 1, then it will fall into case 30 above on the second pass. But if we get here on pass 2, we had better take action directly, because there isn't going to be a pass 3.

⟨MA31 - X is ACTION, Y is NOUNPHRASE 35⟩ ≡

```
    assertion_problem(_P_(C8Case31),
        "an action can't be the same as a thing",
        "so my guess is that this is an attempt to categorise an action which "
        "went wrong because there was already something of that name in "
        "existence. For instance, 'Taking something is theft' would fail if "
        "'theft' was already a value. (But it can also happen with a sentence "
        "which tries to set several actions at once to a named kind of action, "
        "like 'Taking and dropping are manipulation.' - only one can be named "
        "at a time.)");
```

This code is used in §4.

§36. Case 32. Not as unlikely a mistake as it might seem:

Taking something is open.

⟨MA32 - X is ACTION, Y is ADJECTIVE or PROPERTYNOUN - P 36⟩ ≡

```
    assertion_problem(_P_(C8Case32),
        "that is already the name of a property",
        "so it will only confuse things if we use it for a kind of action.");
```

This code is used in §4.

§**37. Case 33.** Whereas this one is frankly remote.

Taking something is 100. The turn count is taking something.

⟨MA33 - X or Y is ACTION - P 37⟩ ≡
```
assertion_problem(_P_(C8Case33),
    "that means something else already",
    "so it will only confuse things if we use it for a kind of action.");
```

This code is used in §4.

§**38. Case 34.** A problem message issued purely on stylistic grounds, though it would be easy to comply with the likely intended sense of the sentence.

⟨MA34 - X is NOUNPHRASE, Y is ACTION - P 38⟩ ≡
```
assertion_problem(_P_(C8Case34),
    "that is putting the definition back to front",
    "since I need these categorisations of actions to take the form "
    "'Kissing a woman is love', not 'Love is kissing a woman'. (This "
    "is really because it is better style: love might be many other "
    "things too, and we don't want to imply that the present definition "
    "is all-inclusive.)");
```

This code is used in §4.

§**39. Case 35.**

⟨MA35 - X is KIND - P 39⟩ ≡
```
assertion_problem(_P_(C8Case35),
    "that seems to say that a new kind is the same as something else",
    "like saying 'A kind of container is a canister': which ought to "
    "be put the other way round, 'A canister is a kind of container'.");
```

This code is used in §4.

§**40. Case 36.** Equating something to a single adjective.

The desk is fixed in place. A container is usually fixed in place.

⟨MA36 - X is INSTANCE or NOUNPHRASE or VALUE, Y is ADJECTIVE 40⟩ ≡
```
if [[px == player]] {
    pn_make_player_noun_phrase(px);
    /* make_assertion_recursive(px, py, assertion_depth);
    return; */
}
if (traverse == 2) assert_property_list(px, py);
```

This code is used in §4.

§41. Case 37.

⟨MA37 - X is NOUNPHRASE or VALUE, Y is PROPERTYNOUN - P 41⟩ ≡

```
assertion_problem(_P_(C8Case37),
    "that seems to say that some object is a property",
    "like saying 'The brick building is the description': if you want "
    "to specify the description of the current object, try putting "
    "the sentence the other way around ('The description is...').");
```

This code is used in §4.

§42. Case 38. I am in two minds about the next nit-picking error message. But really this is a device used in English only for declamatory purposes or comedic intent. (As in Peter Schickele's spoof example of an 18th-century opera about a dog, *Collared Is Bowser*.)

⟨MA38 - X is ADJECTIVE, Y is NOUNPHRASE - P 42⟩ ≡

```
assertion_problem(_P_(C8Case38),
    "that seems to say that an adjective is a noun",
    "like saying 'Open are the doubled doors': which I'm picky about, "
    "preferring it written the other way about ('The doubled doors are "
    "open'). Less poetic, but clearer style.");
```

This code is used in §4.

§43. Case 39.

⟨MA39 - X, Y are ADJECTIVE, PROPERTYNOUN or PROPERTYLIST - P 43⟩ ≡

```
assertion_problem(_P_(C8Case39),
    "that seems to say that an either/or property is the same as "
    "a property which has a value",
    "like saying 'Open is the description': it makes no grammatical "
    "sense even if we know what object is being talked about.");
```

This code is used in §4.

§44. Case 40.

⟨MA40 - X, Y are PROPERTYLIST or PROPERTYNOUN - P 44⟩ ≡

```
assertion_problem(_P_(C8Case40),
    "that seems to say that two different properties are the same",
    "like saying 'The indefinite article is the printed name': that "
    "might be true for some things, some of the time, but it makes "
    "no sense in a general statement like this one.");
```

This code is used in §4.

§45. Case 41.

⟨MA41 - X is ADJECTIVE, Y is VALUE - P 45⟩ ≡

```
assertion_problem(_P_(C8Case41),
    "that suggests that an adjective has some sort of value",
    "like saying 'Open is a number' or 'Scenery is 5': but of course "
    "an adjective represents something which is either true or false.");
```

This code is used in §4.

§**46. Case 42.** Such implicatory sentences as

Scenery is usually fixed in place.

⟨MA42 - X, Y are ADJECTIVE 46⟩ ≡
```
if (traverse == 2) {
    imp_new(px, py);
}
```

This code is used in §4.

§**47. Case 43.** This is unlikely to be called as a top-level sentence with "is", but will instead occur through recursion from `WITH_NT` nodes, or as part of the handling of "to have" rather than "to be". Anyway, it behaves as if the verb were "has" not "is".

Property lists may contain references to things not yet created, if we assert them during pass 1: so we wait until pass 2.

⟨MA43 - X is NOUNPHRASE, Y is PROPERTYLIST 47⟩ ≡
```
if (traverse == 2) assert_property_list(px, py);
```

This code is used in §4.

§**48. Case 44.** And vice versa. This case can only arise through recursion.

⟨MA44 - X is PROPERTYLIST, Y is NOUNPHRASE 48⟩ ≡
```
if (traverse == 2) assert_property_list(py, px);
```

This code is used in §4.

§**49. Case 45.** Assigning a property list to something makes it tangible. This puts us back into case 43.

⟨MA45 - X is INSTANCE, Y is PROPERTYLIST 49⟩ ≡
```
if (current_sentence->down->next == px) {
    if (traverse == 2) assert_property_list(px, py);
} else {
    convert_instance_to_nounphrase(px, assertion_depth, FALSE);
    make_assertion_recursive(px, py, assertion_depth);
}
```

This code is used in §4.

§**50. Case 46.** And vice versa, but into case 44.

⟨MA46 - X is PROPERTYLIST, Y is INSTANCE 50⟩ ≡
```
if (current_sentence->down->next->next == py) {
    if (traverse == 2) assert_property_list(py, px);
} else {
    convert_instance_to_nounphrase(py, assertion_depth, FALSE);
    make_assertion_recursive(px, py, assertion_depth);
}
```

This code is used in §4.

§**51. Case 47.** This one used to be invalid, but became an active case in August 2008 when value properties for other values were put on a par with those for objects.

⟨MA47 - X, Y are PROPERTYLIST, VALUE 51⟩ ≡

```
if ((pn_get_node_type(px) == VALUE_NT) &&
    (spec_is_CONSTANT_of_kova(pn_get_evaluation(px), RULEBOOK_TY))) {
    if (traverse == 2)
        rb_parse_properties(
            RULEBOOK_spec_to_rulebook(pn_get_evaluation(px)),
            left_edge_of(py), right_edge_of(py));
    return;
}
if (traverse == 2) assert_property_list(px, py);
```

This code is used in §4.

§**52. Case 48.** "In A is a B with I": process as "In A is a B" followed by "the newly created B is I".

```
In the Pitch is a container with description "Made of wood."
```

⟨MA48 - X is RELATIONSHIP, Y is WITH 52⟩ ≡

```
make_assertion_recursive(px, py->down, assertion_depth);
make_assertion_recursive(py->down, py->down->next, assertion_depth);
```

This code is used in §4.

§**53. Case 49.** "An A with I is in B": similar.

⟨MA49 - X is WITH, Y is RELATIONSHIP 53⟩ ≡

```
make_assertion_recursive(px->down, py, assertion_depth);
make_assertion_recursive(px->down, px->down->next, assertion_depth);
```

This code is used in §4.

§**54. Case 50.** "X is every K" and other oddities.

⟨MA50 - Y is EVERY 54⟩ ≡

```
if [[py == everywhere]] {
    pn_set_node_type(py, INSTANCE_NT);
    pn_set_refers_to(py, kind_room);
    make_assertion_recursive(px, py, assertion_depth);
    return;
}
assertion_problem(_P_(C8Case50),
    "'every' can't be used in that way",
    "and should be reserved for sentences like 'A coin is in every room'.");
```

This code is used in §4.

§**55. Case 51.** "Every K is Y" and other oddities.

⟨MA51 - X is EVERY - P 55⟩ ≡
```
assertion_problem(_P_(C8Case51),
    "'every' can't be used in that way",
    "and should be reserved for sentences like 'A coin is in every room'.");
```

This code is used in §4.

§**56. Case 52.** "Every K is every L."

⟨MA52 - X, Y are EVERY - P 56⟩ ≡
```
assertion_problem(_P_(C8Case52),
    "I can't do that", "Dave.");
```

This code is used in §4.

§**57. Case 53.** "Every K is in L."

⟨MA53 - X is EVERY, Y is RELATIONSHIP 57⟩ ≡
```
make_generalisation(px, py);
```

This code is used in §4.

§**58. Case 54.** "The colour of the paint is white."

⟨MA54 - X is XOFY, Y is ADJECTIVE 58⟩ ≡
```
if (traverse == 1) return;
if ((pn_get_property(py)) && (pn_get_evaluation(py))) {
    if [[px->down == player]]
        pn_make_player_noun_phrase(px->down);
    if (pn_get_refers_to(px->down))
        assert_property_value_from_property_subtree(value_property_name_ref(
            px->down->next->word_ref1, px->down->next->word_ref2),
            pn_get_refers_to(px->down), NULL, py);
    else
        assert_property_value_from_property_subtree(value_property_name_ref(
            px->down->next->word_ref1, px->down->next->word_ref2),
            NULL, pn_get_evaluation(px->down), py);
} else {
    assertion_problem(_P_(C8Case54),
        "that property can't be used adjectivally as a value",
        "since it is an adjective applying to a thing but is "
        "not a name from a range of possibilities.");
}
```

This code is used in §4.

§**59. Case 55.** To do with value relations.

⟨MA55 - X is RELATIONSHIP, Y is VALUE 59⟩ ≡

```
if [[py == player]] {
    pn_make_player_noun_phrase(py);
    make_assertion_recursive(px, py, assertion_depth);
    return;
}
if ((pn_get_relationship(px)) &&
    (bp_relates_values_not_objects(pn_get_relationship(px))))
    assert_subtree_in_relationship(py, px);
else {
assertion_problem(_P_(C8Case55),
    "this seems to give a worldly relationship to something intangible",
    "possibly due to an accidental clash of names between a kind of "
    "value and something in the real world. "
    "I sometimes read sentences like 'There is a number on the "
    "door' or 'A text is in the prayer-box' literally - thinking "
    "you mean a whole number or a piece of double-quoted text, and "
    "not realising you intended to make a brass number-plate or "
    "an old book. If that's the trouble, you can use 'called': "
    "for instance, 'In the prayer-box is a thing called the text.'");
}
```

This code is used in §4.

§**60. Case 56.** To do with value relations.

⟨MA56 - X is VALUE, Y is RELATIONSHIP 60⟩ ≡

```
if [[px == player]] {
    pn_make_player_noun_phrase(px);
    make_assertion_recursive(px, py, assertion_depth);
    return;
}
if ((pn_get_relationship(py)) &&
    (bp_relates_values_not_objects(pn_get_relationship(py))))
    assert_subtree_in_relationship(px, py);
else {
assertion_problem(_P_(C8Case56),
    "this seems to give a worldly relationship to something intangible",
    "possibly due to an accidental clash of names between a kind of "
    "value and something in the real world. "
    "I sometimes read sentences like 'There is a number on the "
    "door' or 'A text is in the prayer-box' literally - thinking "
    "you mean a whole number or a piece of double-quoted text, and "
    "not realising you intended to make a brass number-plate or "
    "an old book. If that's the trouble, you can use 'called': "
    "for instance, 'In the prayer-box is a thing called the text.'");
}
```

This code is used in §4.

§**61. Case 57.** To catch confusions of action names with values.

⟨MA57 - X is VALUE, Y is ACTION 61⟩ ≡

```
quote_source(1, current_sentence);
quote_source(2, py);
handmade_problem(_P_(C8Case57));
issue_problem_segment(
    "You wrote %1: unfortunately %2 is already the name of an action, "
    "and it would only confuse things if we used it for a value as well.");
issue_problem_end();
```

This code is used in §4.

§**62. Adjective list trees.**

```
int is_adjlist(parse_node *p) {
    if (p == NULL) return FALSE;
    switch (pn_get_node_type(p)) {
        case ADJECTIVE_NT: return TRUE;
        case AND_NT: return ((is_adjlist(p->down)) && (is_adjlist(p->down->next)));
        default: return FALSE;
    }
}
```

§**63. Equating values.** This is never allowed, but there are a variety of possible problem messages, because it usually occurs as a symptom of a failed attempt to create something.

```
void issue_value_equation_problem(parse_node *px, parse_node *py) {
    if ((pn_get_node_type(px) != NOUNPHRASE_NT) || (pn_get_node_type(py) != VALUE_NT)) {
        log_subtree(px, 1); log_subtree(py, 1);
        internal_error("Assert PX of type PY on bad node types");
    }
    log_subtree(px,1); log_subtree(py,1);
    if ((spec_is_actual_CONSTANT(pn_get_evaluation(py)) == FALSE) &&
        (is_kova(spec_get_kind_of_value(pn_get_evaluation(py)), OBJECT_TY))) {
        sentence_problem(_P_(C8NoObjects),
            "that's not something which you can create new values of",
            "because you need to be more specific about what kind of "
            "object is intended. Thus 'The frog is an animal' or "
            "'The Hallway is a room' are fine, but not 'The cabinet "
            "is an object' or 'There is an object called the clock'. "
            "(If in doubt, call it a 'thing' instead of an 'object'.)");
        return;
    }
    if ((current_sentence) &&
        (is_word_intermediate_inc(something_V,
        current_sentence->word_ref1, current_sentence->word_ref2) >= 0)) {
        sentence_problem(_P_(C8EquatesSomethingToValue),
            "that seems to say that an object is the same as a value",
            "which must be wrong. This can happen if the word 'something' is "
            "used loosely - I read it as 'some thing', so I think it has to "
            "refer to a thing, which is a kind of object. A sentence like "
```

```
            "'Something called mauve is a colour' trips me up because mauve "
            "is a value, so it isn't an object, and doesn't match 'something'.");
        return;
    }
    if ((pn_get_refers_to(px)) &&
        (pn_get_refers_to(px)->creating_sentence != current_sentence)) {
        quote_words(1, px->word_ref1, px->word_ref2);
        quote_source(2, current_sentence);
        quote_source(3, pn_get_refers_to(px)->creating_sentence);
        handmade_problem(_P_(C8CantUncreate));
        issue_problem_segment(
            "In order to act on %2, I seem to need to give "
            "a new meaning to '%1', something which was created by the earlier "
            "sentence %3. That must be wrong somehow: I'm guessing that there "
            "is an accidental clash of names. This sometimes happens when "
            "adjectives are being made after objects whose names include them: "
            "for instance, defining 'big' as an adjective after having already "
            "made a 'big top'. The simplest way to avoid this is to define "
            "the adjectives in question first.");
        issue_problem_end();
        return;
    }
    sentence_problem(_P_(BelievedImpossible),
        "that seems to say that an object is the same as a value",
        "which must be wrong.");
}
```

§**64. To Be and To Have.** Well, that ought to be the name of an incomprehensible book by Sartre which dismisses Heidegger's seminal *To Have and To Be*, or something like that, but instead it is the name of a section which contains the two wrapper routines for the main English assertion verbs.

```
sentence_handler ASSERT_SH_handler = { SENTENCE_NT, ASSERT_VB, 0, to_be };
sentence_handler HAS_SH_handler = { SENTENCE_NT, HAS_VB, 0, to_have };
void to_be(parse_node *pv) {
    parse_node *px = pv->down->next;
    parse_node *py = pv->down->next->next;
    if ((px->word_ref1 >= 0) && (px->word_ref2 > px->word_ref1)
        && (vocab_test_flags(px->word_ref1, TEXT_MC))) {
        sentence_problem(_P_(C8TextNotClosing),
            "it looks as if perhaps you did not intend that to read as a "
            "single sentence",
            "and possibly the text in quotes was supposed to stand as "
            "as a sentence on its own? (The convention is that if text "
            "ends in a full stop, exclamation or question mark, perhaps "
            "with a close bracket or quotation mark involved as well, then "
            "that punctuation mark also closes the sentence to which the "
            "text belongs: but otherwise the words following the quoted "
            "text are considered part of the same sentence.)");
        return;
    }
    make_assertion(px, py);
}
```

§**65.** Note that `to_have` converts its sentence subtree to a case of "to be", so that it is only called on traverse 1: by the time of traverse 2, all "have" sentences have been converted. Generally speaking we construe the Y in "X has Y" as a property list, but with certain exceptions:

X has an A called B → X is allowed to have an A called B

X has A → X is A

X has Q → X is allowed to have Q

The last of these handles sentences like "X has a colour", where "colour" is a kind of value which will be allowed to coincide with the name of a property. ("Is allowed to have..." is pseudo-code here: this is no longer syntax which I7 recognises directly, although it used to be in early drafts of NI. What really happens is that we manufacture a suitable `ALLOWED_NT` structure.)

```
void to_have(parse_node *pv) {
    int make_pl = TRUE;
    parse_node *px = pv->down->next;
    parse_node *py = pv->down->next->next;
    if (pn_get_node_type(py) == X_OF_Y_NT) {
        LOG("Sentence subtree:\n$T\n", current_sentence);
        sentence_problem(_P_(C8SuperfluousOf),
            "the 'of' here appears superfluous",
            "assuming the sentence aims to give a property value of something. "
            "(For instance, if we want to declare the carrying capacity of "
            "something, the normal Inform practice is to say 'The box has "
            "carrying capacity 10' rather than 'The box has a carrying capacity "
            "of 10'.)");
        return;
    }
    if (pn_get_node_type(py) == WITH_NT) {
        LOG("Sentence subtree:\n$T\n", current_sentence);
        sentence_problem(_P_(C8SuperfluousWith),
            "the 'has ... with' here appears to be a mixture of two ways to "
            "give something properties",
            "that is, 'The box is a container with capacity 10.' and 'The box "
            "has capacity 10.'");
        return;
    }
    if (pn_get_node_type(py) == CALLED_NT) {
        pn_set_node_type(py, PROPERTYCALLED_NT);

```

Assemblies 8/assem

Purpose

To build the complex multi-object assemblies which result from allowing the source text to say things like "in every room is a vehicle".

Definitions

¶1. Generalisations are essentially fragments of parse tree stored for later use. They handle sentences like

> In every container is a coin.

which are done by recognising the prototype part ("in every container") in the parse tree and grafting on a duplicate of the assembly part ("a coin") in place of the EVERY subtree ("every container"). Sometimes the EVERY subtree is the whole prototype subtree ("Every coin is on a table"), in which case `px` and `substitute_at` in the following structure coincide.

Each kind (in this example "container") keeps a linked list of the generalisations which apply to it.

```
typedef struct generalisation {
    struct parse_node *px;                          prototype situation to look for
    struct parse_node *py;                          subtree for what to assemble
    struct parse_node *substitute_at;               position under px of the EVERY node
    struct parse_node copied;                       a deep copy of py
    struct generalisation *next;                    next in list of generalisations about kind
    MEMORY_MANAGEMENT
} generalisation;
```

The structure generalisation is private to this section.

---

§**1.** Assemblies are made when an object of a given kind is created, and when generalisations about that kind mean that further creations are also needed. For instance: if a generalisation has said that every container contains a shoe, then each time a container is created, we also need to create a shoe, and assert a spatial relationship between them. In practice we do this by a simple process which involves cutting and pasting of subtrees of the parse tree, for which the following utility is helpful:

```
void deep_copy_tree(parse_node *from, parse_node *to, int level) {
    if ((from == NULL) || (to == NULL)) internal_error("Null deep copy");
    pn_copy(to, from);
    if (from->down) {
        to->down = new_node(NOUNPHRASE_NT);
        deep_copy_tree(from->down, to->down, level+1);
    }
    if ((level>0) && (from->next)) {
        to->next = new_node(NOUNPHRASE_NT);
        deep_copy_tree(from->next, to->next, level);
    }
}
```

§**2.** Now the actual assembly code.

```
int contains_instance_of_k(parse_node *chunk, world_object *k, int level) {
    if ((pn_get_node_type(chunk) == INSTANCE_NT) && (pn_get_refers_to(chunk) == k))
        return TRUE;
    if ((chunk->down) && (contains_instance_of_k(chunk->down, k, level+1)))
        return TRUE;
    if ((level>0) && (chunk->next) && (contains_instance_of_k(chunk->next, k, level)))
        return TRUE;
    return FALSE;
}

int implicit_recursion_exception = FALSE;

}
```

The function make_generalisation is called from 8/mass.
The function satisfies_generalisations_about is called from 9/kind.

Character Knowledge 8/knowc

Purpose

Character in the sense of the nature of things – both the kind of an object, but also more generally that it satisfies some proposition.

§1. Asserting kinds.

```
void assert_kind_of_object(world_object *wo, world_object *k) {
    prop_true_in_world_model_about(prop_to_set_kind(wo, k), wo, NULL);
}
```

The function assert_kind_of_object is called from 8/creat, 8/mass, 9/spabp and 9/model.

§2. Inferring from INSTANCE nodes.

```
void assert_instance(parse_node *px, parse_node *py) {
    if ((pn_get_node_type(px) != NOUNPHRASE_NT) && (pn_get_node_type(px) != INSTANCE_NT))
        internal_error_on_node_type(px);
    if ((pn_get_node_type(py) != ADJECTIVE_NT) && (pn_get_node_type(py) != INSTANCE_NT))
        internal_error_on_node_type(py);
    world_object *wo = pn_get_refers_to(px);
    if (pn_get_refers_to(py) != NULL) {
        world_object *k = pn_get_refers_to(py);
        if (wo == k) { equated_descriptions_problem(k, k); return; }
        if ((current_sentence != wo->creating_sentence) &&
            (wo_of_kind(wo, kind_region) == FALSE) && (k == kind_region)) {
            object_problem_at_sentence(_P_(C8ExistingRegion),
                wo,
                "(which I notice in another sentence) seems now to "
                "be declared as a new region",
                "which is suspect. Perhaps I have misinterpreted what was "
                "meant to be a new name for an old one?");
            return;
        }
        if ((wo) && (wo->kind_flag) && (k) && (k->kind_flag)) {
            if (((wo == kind_backdrop) || (wo_of_kind(wo, kind_backdrop))) &&
                (is_word_intermediate_inc(everywhere_V,
                    current_sentence->word_ref1, current_sentence->word_ref2))) {
                object_problem_at_sentence(_P_(C8KindOfBackdropEverywhere),
                    wo,
                    "seems to be said to be 'everywhere' in some way",
                    "which doesn't make sense. An individual backdrop can be 'everywhere',
"
                    "but here we're talking about a whole kind, and it's not allowed "
                    "to talk about general locations of a whole kind of things at once.");
                return;
            } else equated_descriptions_problem(wo, k); return;
        }
```

```
    }

        issue_problem_segment(
            "The sentence %1 seems to be telling me that two descriptions, "
            "one a form of %2 and the other of %3, are the same. That's a "
            "little puzzling - like saying that 'An open door is a container.' %P"
            NAME_DESCRIPTION_CLASH_NOTE);
        issue_problem_end();
    }
}
```

The function equated_descriptions_problem is called from 8/mass.

Property Knowledge 8/knowp

Purpose

This section draws inferences from assertions which seem to be about the properties of things, independent of their location.

8/knowp.§1 One way to assert global variable values; §2-4 Three ways to assert properties

---

§**1. One way to assert global variable values.** A global like "score" is in effect a property belonging to no single object, and which therefore exists only once.

```
void initialise_global_variable(quantity *q, specification *val,
    parse_node *where_from) {
    kind_of_value *variable_kov = qty_kind_of_value(q);
    kind_of_value *constant_kov = spec_evaluates_to(val);
    if (can_we_cast_kovs(constant_kov, variable_kov) != ALWAYS_MATCH) {
        specification *dummy1 = new_generic_CONSTANT_type(variable_kov),
            *dummy2 = new_generic_CONSTANT_type(constant_kov);
        quote_source(1, current_sentence);
        quote_words(2, q->word_ref1, q->word_ref2);
        if (where_from) quote_words(3, where_from->word_ref1, where_from->word_ref2);
        else quote_spec(3, val);
        quote_spec(4, dummy1);
        quote_spec(5, dummy2);
        if ((kovko_get_kind(variable_kov)) && (spec_is_nothing_object_constant(val))) {
            handmade_problem(_P_(C8QuantityKindNothing));
            issue_problem_segment(
                "The sentence %1 tells me that '%2', which should be %4 "
                "that varies, is to have the initial value 'nothing'. "
                "This is allowed as an 'object which varies', but the "
                "rules are stricter for %4.");
            issue_problem_end();
        } else {
            handmade_problem(_P_(C8GlobalKindWrong));
            issue_problem_segment(
                "The sentence %1 tells me that '%2', which is %4 that varies, "
                "should start out with the value '%3', but this is %5 and not %4.");
            issue_problem_end();
        }
        return;
    }
    specification *var = new_actual_NONLOCAL_VARIABLE_type(q);
    int spm = prevailing_mood;
    if (prevailing_mood == UNKNOWN_CE) prevailing_mood = CERTAIN_CE;
    prevailing_mood = spm;
    prop_true_in_world_model(prop_to_set_relation(a_is_b_predicate, NULL, var, NULL, val));
}
```

The function initialise_global_variable is called from 8/mass, 10/tab and 10/bib.

§**2. Three ways to assert properties.** In these three alternative routines, we can assert that a given owner – specified either as an object, a value or a subtree – should have

(a) a given single property equal to a value given as a subtree,
(b) a given single property equal to an explicit value, or
(c) a whole list of properties and their values.

```
void assert_property_value_from_property_subtree(property_name *prn,
    world_object *owner_wo, specification *owner_spec, parse_node *val_subtree) {
    if (property_owner_acceptable(owner_wo, owner_spec, NULL))
        prop_true_in_world_model_about(prop_from_property_subtree(prn, val_subtree),
            owner_wo, owner_spec);
}

void assert_property_value_explicitly(property_name *prn,
    world_object *owner_wo, specification *owner_spec, specification *val) {
    if (property_owner_acceptable(owner_wo, owner_spec, NULL))
        prop_true_in_world_model_about(prop_to_set_property(prn, val),
            owner_wo, owner_spec);
}

void assert_property_list(parse_node *owner_subtree, parse_node *list_subtree) {
    world_object *owner_wo = pn_get_refers_to(owner_subtree);
    specification *owner_spec = pn_get_evaluation(owner_subtree);
    kind_of_value *kov = property_owner_acceptable(owner_wo, owner_spec, owner_subtree);
    if (owner_wo) owner_spec = NULL;
    if (kov)
        prop_true_in_world_model_about(prop_from_property_list(list_subtree, kov),
            owner_wo, owner_spec);
}
```

The function assert_property_value_from_property_subtree is called from 8/mass, 9/pp and 10/tab.
The function assert_property_value_explicitly is called from 9/model.
The function assert_property_list is called from 6/treec, 8/creat and 8/mass.

§**3.**

```
kind_of_value *property_owner_acceptable(world_object *owner_wo, specification *owner_spec,
    parse_node *owner_subtree) {
    kind_of_value *kov = NULL;
    if (species_is(owner_spec, DESCRIPTION_SPC)) {
        if ((number_of_adjectives_applied_to(owner_spec) > 0) ||
            (prop_contains_adjective(spec_get_proposition(owner_spec)))) {
            quote_source(1, current_sentence);
            quote_source(2, owner_subtree);
            handmade_problem(_P_(C8AdjectiveAPL));
            issue_problem_segment(
                "The sentence %1 looked to me as if it might be trying "
                "to assign certain properties to something described "
                "in a way (%2) which involved an adjective which can't be "
                "properly understood until the game is running, so "
                "that at this point it's impossible to act upon.");
            issue_problem_end();
            return NULL;
        }
        if (prop_contains_binary_predicate(spec_get_proposition(owner_spec))) {
```

```
            quote_source(1, current_sentence);
            quote_source(2, owner_subtree);
            handmade_problem(_P_(C8RelationAPL));
            issue_problem_segment(
                "The sentence %1 looked to me as if it might be trying "
                "to assign certain properties to something described "
                "in a way (%2) which involved a clause which can't be "
                "properly determined until the game is running, so "
                "that at this point it's impossible to act upon.");
            issue_problem_end();
            return NULL;
        }
    }
    if (owner_subtree) {
        if ((spec_is_actual_CONSTANT(owner_spec) || spec_is_generic_CONSTANT(owner_spec))) {
            owner_wo = NULL;
        } else if (owner_wo) {
            kov = kova(OBJECT_TY); owner_spec = NULL;
        } else { owner_spec = NULL; owner_wo = NULL; }
    }
    if (owner_spec) kov = spec_get_kind_of_value(owner_spec);
    else if (owner_wo) kov = kova(OBJECT_TY);
    else issue_bad_owner_problem();
    return kov;
}
void issue_bad_owner_problem(void) {
    quote_source(1, current_sentence);
    handmade_problem(_P_(C8BadPropertyOwner));
    issue_problem_segment(
        "The sentence %1 looked to me as if it might be trying "
        "to assign certain properties to something "
        "which is not allowed to have properties at all.");
    issue_problem_end();
}
```

The function issue_bad_owner_problem is called from 9/inf.

§4. The following assumes that the subtree `py` describes a value which the `prn` property of something will have; it issues problem messages if this would be impossible, returning `NULL`, or else silently returns the value. It's used both above and by the tree-conversion code in the predicate calculus engine.

```
specification *property_value_from_property_subtree(property_name *prn, parse_node *py) {
    specification *val = NULL;
    int type_mismatch = FALSE;

The function property_value_from_property_subtree is called from 6/treec.

Relation Knowledge 8/relv

Purpose

This section draws inferences about the relationships between objects or values.

§**1. Relationship nodes.** Here we have a relationship between subtrees T_X and T_Y, where T_X must be a list of values or objects (joined into an `AND_NT` tree), and T_Y must be a `RELATIONSHIP_NT` subtree – which is usually a node annotated with the predicate meant, and beneath that another list of objects or values, but there are two exceptional cases to take care of.

```
void assert_subtree_in_relationship(parse_node *px, parse_node *relationship_subtree) {
    if ((px == NULL) || (relationship_subtree == NULL))
        internal_error("assert relation between null subtrees");
    if (pn_get_node_type(relationship_subtree) != RELATIONSHIP_NT)
        internal_error("asserted malformed relationship subtree");
    if (pn_get_node_type(px) == AND_NT) {
        assert_subtree_in_relationship(px->down, relationship_subtree);
        assert_subtree_in_relationship(px->down->next, relationship_subtree);
        return;
    }
    if (traverse == 1) return;
    switch(pn_int_annotation(relationship_subtree, relationship_node_type_ANNOT)) {
        case PARENTAGE_HERE_RELN: ⟨Exceptional relationship nodes for placing objects "here" 3⟩;
        case DIRECTION_RELN: ⟨Exceptional relationship nodes for map connections 4⟩;
        case STANDARD_RELN: ⟨Standard relationship nodes (the vast majority) 2⟩;
        default: internal_error("unknown RELATIONSHIP node type");
    }
}
```

The function assert_subtree_in_relationship is called from 8/mass.

§**2.**

⟨Standard relationship nodes (the vast majority) 2⟩ ≡

```
    binary_predicate *bp = bp_get_reversal(pn_get_relationship(relationship_subtree));
    if (bp == NULL) internal_error("asserted bp-less relationship subtree");
    fix_property_bp(bp);
    assert_relation_between_subtrees(px, bp, relationship_subtree->down);
    break;
```

This code is used in §1.

§3.

⟨Exceptional relationship nodes for placing objects "here" 3⟩ ≡

```
    if (relationship_subtree->down) internal_error("malformed PARENTAGE");
    if (traverse == 1) return;
    world_object *wo = pn_get_refers_to(px);
    specification *spec = pn_get_evaluation(px);
    if (wo) spec = NULL;
    prop_true_in_world_model_about(prop_to_put_here(), wo, spec);
    break;
```

This code is used in §1.

§4.

⟨Exceptional relationship nodes for map connections 4⟩ ≡

```
    if (relationship_subtree->down == NULL) internal_error("malformed DIRECTION");
    if (pn_get_node_type(relationship_subtree->down) != NOUNPHRASE_NT) {
        sentence_problem(_P_(BelievedImpossible),
            "this is not straightforward enough in saying which "
            "room (or door) leads away from",
            "and should just name the source.");
        break;
    }
    if (relationship_subtree->down->next == NULL) internal_error("malformed DIRECTION");
    if (relationship_subtree->down->next->next != NULL) internal_error("malformed DIRECTION");
    if (pn_get_node_type(relationship_subtree->down->next) != NOUNPHRASE_NT) {
        sentence_problem(_P_(BelievedImpossible),
            "this is not straightforward enough in saying which "
            "direction the room (or door) lies in",
            "and should just name the direction.");
        break;
    }
    if (traverse == 1) return;
    world_object *oy = pn_get_refers_to(relationship_subtree->down);
    world_object *od = pn_get_refers_to(relationship_subtree->down->next);
    if ((oy == NULL) || (od == NULL) || (is_a_direction_object(od) == FALSE))
        internal_error("malformed directional subtree");
    make_map_connection(oy, pn_get_refers_to(px), od);
    break;
```

This code is used in §1.

§**5. Relating subtrees.** And here we have a relationship between subtrees T_X and T_Y, where T_X is a single value or object and T_Y is a list of values or objects (joined into an `AND_NT` tree).

```
void assert_relation_between_subtrees(parse_node *px,
    binary_predicate *bp, parse_node *py) {
    if (pn_get_node_type(py) == AND_NT) {
        assert_relation_between_subtrees(px, bp, py->down);
        assert_relation_between_subtrees(px, bp, py->down->next);
        return;
    }
    if (pn_get_node_type(py) == EVERY_NT) {
        sentence_problem(_P_(C8EveryWrongSide),
            "'every' can only be used on the other side of the verb",
            "because of limitations in Inform (but also to avoid certain "
            "possible ambiguities). In general, 'every' should be applied "
            "to the subject of an assertion sentence and not the object. "
            "Thus 'Sir Francis prefers every blonde' is not allowed, but "
            "'Every blonde is preferred by Sir Francis' is.");
            return;
    }
    reverse the relation (and swap the terms) to ensure it's the right way round
    if (bp_is_the_wrong_way_round(bp)) {
        parse_node *pz = px; px = py; py = pz;
        bp = bp_get_reversal(bp);
    }
    treat adjectives like "green" as nouns if possible
    if (pn_get_node_type(px) == ADJECTIVE_NT) pn_set_node_type(px, VALUE_NT);
    if (pn_get_node_type(py) == ADJECTIVE_NT) pn_set_node_type(py, VALUE_NT);
    treat "the player" as referring to the default player, not the variable
    turn_player_to_yourself(px);
    turn_player_to_yourself(py);
    if (((pn_get_node_type(px) != NOUNPHRASE_NT) &&
        (pn_get_node_type(px) != INSTANCE_NT) &&
        (pn_get_node_type(px) != VALUE_NT)) ||
        ((pn_get_node_type(py) != NOUNPHRASE_NT) &&
        (pn_get_node_type(py) != INSTANCE_NT) &&
        (pn_get_node_type(py) != VALUE_NT))) {
        sentence_problem(_P_(C8BadRelation),
            "this description of a relationship makes no sense to me",
            "and should be something like 'X is in Y' (or 'on' or 'part of Y'); "
            "or else 'X is here' or 'X is east of Y'.");
    }
    if ((bp_relates_values_not_objects(bp)) &&
        (((pn_get_refers_to(px)) && (pn_get_refers_to(px)->kind_flag)) ||
        ((pn_get_refers_to(py)) && (pn_get_refers_to(py)->kind_flag)))) {
        sentence_problem(_P_(C8KindRelatedToValue),
            "relations between objects and values have to be made one "
            "object at a time",
            "not using kinds of object to make multiple relationships in "
            "a single sentence. (Sorry for this restriction.)");
        return;
    }
```

```
    if (traverse == 1) return;
    world_object *wo0 = NULL, *wo1 = NULL;
    specification *spec0 = NULL, *spec1 = NULL;
    if (pn_get_refers_to(px)) wo0 = pn_get_refers_to(px);
    else spec0 = pn_get_evaluation(px);
    if (pn_get_refers_to(py)) wo1 = pn_get_refers_to(py);
    else spec1 = pn_get_evaluation(py);
    prop_true_in_world_model(prop_to_set_relation(bp, wo0, spec0, wo1, spec1));
}
```

§**6. The map-connector.** Now we come to the code which creates map connections. This needs special treatment only so that asserting $M(X, Y)$ also asserts $M'(Y, X)$, where M' is the predicate for the opposite direction to M; but since this is only a guess, it drops from `CERTAIN_CE` to merely `LIKELY_CE`.

However, the map-connector can also run in one-way mode, where it doesn't make this guess; so we begin with switching in and out.

```
int oneway_map_connections_only = FALSE;
void enter_one_way_mapping_mode(void) {
    oneway_map_connections_only = TRUE;
}
void exit_one_way_mapping_mode(void) {
    oneway_map_connections_only = FALSE;
}
```

The function enter_one_way_mapping_mode is called from 8/mass.
The function exit_one_way_mapping_mode is called from 8/mass.

§**7.** Note that, in order to make the conjectural reverse map direction, we need to look up the "opposite" property of the forward one. This relies on all directions having their opposites defined before any map is built, and is the reason for Inform's insistence that directions are always created in matched pairs.

```
void make_map_connection(world_object *go_from, world_object *go_to,
    world_object *forwards_dir) {
    world_object *reverse_dir = get_value_of_opposite_property(forwards_dir);
    if (traverse == 1) return;
    oneway_map_connection(go_from, go_to, forwards_dir, CERTAIN_CE);
    if (oneway_map_connections_only) return;
    if ((reverse_dir) && (go_to))
        oneway_map_connection(go_to, go_from, reverse_dir, LIKELY_CE);
}
void oneway_map_connection(world_object *go_from, world_object *go_to,
    world_object *forwards_dir, int certainty_level) {
    binary_predicate *bp = bp_for_mapping_direction(forwards_dir);
    if (bp == NULL) internal_error("map connection in non-direction");
    int pm = prevailing_mood;
    prevailing_mood = certainty_level;
    prop_true_in_world_model_about(prop_to_set_mapping_relation(bp, go_to),
        go_from, NULL);
    prevailing_mood = pm;
}
```

The function make_map_connection is called from 8/mass.

§**8. Everywhere.** Lastly, a simply routine to say that something is everywhere.

```
void assert_object_everywhere(world_object *wo) {
    if (wo_of_kind(wo, kind_backdrop) == FALSE) {
        object_problem(_P_(C8OnlyBackdropsEverywhere),
            wo, "must first be established to be a backdrop",
            "before it can be said to be 'everywhere'. Only backdrops "
            "can be in more than one place at once, and we are only allowed "
            "to talk about one at a time - so we can't say 'A backdrop is "
            "always everywhere', for instance.");
        return;
    }
    prop_true_in_world_model_about(prop_to_put_everywhere(), wo, NULL);
}
```

The function assert_object_everywhere is called from 8/mass.

Implications 8/imp

Purpose

To keep track of a dangerous form of super-assertion called an implication, which is allowed to generalise about properties.

8/imp.§1-4 Implication checking

Definitions

¶1. Implications are structures are used to store the information in sentences like "Something worn is usually wearable and initially carried." The "something worn" part must turn out to be a description of a category of objects; the "usually" part translates into a level of certainty. We regard these as implications in the sense of IF condition A, THEN condition B, but note that A is quite restricted in what it can be: it must be a simple-to-test description only, whereas B could be any subtree of an assertion.

```
typedef struct implication {
    struct specification *if_spec;                    which objects are affected
    struct parse_node *then_pn;                       what assertion is implied about them
    int implied_likelihood;                           with what certainty level
    struct implication *next_implication;             in list of implications
    MEMORY_MANAGEMENT
} implication;
```

The structure implication is private to this section.

¶2. We also need a little piece of storage attached to each property name:

```
typedef struct possession_marker {
    int possessed;                    temporary use when checking implications about objects
    int possession_certainty;                                                        ditto
} possession_marker;
```

The structure possession_marker is private to this section.

```
void imp_new(parse_node *px, parse_node *py) {
    implication *imp;
    world_object *wo;
    property_name *prn;
    if (prevailing_mood == CERTAIN_CE) {
        sentence_problem(_P_(C8ImplicationCertain),
            "that's an implication which is too certain for me",
            "since a sentence like this talks about a generality of things "
            "in terms of one either/or property implying another, and "
            "I can only handle those as likelihoods. You should probably "
            "add 'usually' somewhere: e.g., 'An open door is usually "
            "openable'. (But implications can have unpredictable "
            "consequences: best to avoid them altogether where possible.)");
        return;
    }
    if (pn_get_node_type(py) == AND_NT) {
```

```
        imp_new(px, py->down);
        imp_new(px, py->down->next);
        return;
    }
    imp = CREATE(implication);
    if (pn_get_node_type(px) == WITH_NT) {
        wo = pn_get_refers_to(px->down);
        imp->if_spec = pn_get_evaluation(px->down);
        if (wo == NULL) internal_error("Implication for null instance");
    } else {
        wo = kind_thing;
        imp->if_spec = pn_get_full_phrase_evaluation(px);
    }
    imp->then_pn = py;
    prn = pn_get_property(imp->then_pn);
    if ((prn) && (prn_is_either_or(prn) == FALSE)) {
        sentence_problem(_P_(C8ImplicationValueProperty),
            "that's an implication where the outcome is a value property",
            "rather than a simple either/or property, which is the only form "
            "of implication I can handle.");
        return;
    }
    imp->implied_likelihood = prevailing_mood;
    imp->next_implication = wo->implies;
    wo->implies = imp;
    LOGIF(IMPLICATIONS, "Forming implication for $O: type $S implies\n  $T",
        wo, imp->if_spec, imp->then_pn);
}
```

The function imp_new is called from 8/mass.

§**1. Implication checking.** For instance, if there is an inference asserting that object X is worn, and there is an implication that what is worn is usually also wearable, then we must generate an inference that X is wearable: in effect, this is a deduction from a syllogism. We should however not generate such an inference if we already have definite knowledge that X is not wearable. We do this for each object X individually.

The following sets flags attached to each boolean property to say whether X has that property, and if so, with what level of certainty.

```
void set_possessed_flags(world_object *wo) {
    inference *inf;
    if ((wo->kind) && (wo->kind != kind_kind)) set_possessed_flags(wo->kind);
    KNOWLEDGE_LOOP(inf, wo, PROPERTY_INF) {
        property_name *prn = inf_get_property_name(inf);
        if (prn_is_either_or(prn)) {
            int truth = TRUE, abc = inf_get_certainty(inf);
            if (abc < 0) {
                abc = -abc;
                truth = FALSE;
            }
            if (abc != 0) {
                possession_marker *pom = prn_get_possession_marker(prn);
                if (pom->possession_certainty < abc) {
                    pom->possessed = truth;
```

```
                    pom->possession_certainty = abc;
                }
                if (prn_either_or_get_negation(prn)) {
                    possession_marker *pom =
                        prn_get_possession_marker(prn_either_or_get_negation(prn));
                    if (pom->possession_certainty < abc) {
                        pom->possessed = 1-truth;
                        pom->possession_certainty = abc;
                    }
                }
            }
        }
    }
}
```

§**2.** Implications are associated with given objects, but usually in fact with kinds: an implication for all containers will apply to any instance of "container", and so forth. In the following, `wo` is the object whose implications are being considered, and `for_wo` is the instance which may be affected.

```
void check_implications_of(world_object *wo, world_object *for_wo) {
    implication *imp;
    if ((wo->kind) && (wo->kind != kind_kind)) check_implications_of(wo->kind, for_wo);
    if (wo->implies) {
        LOGIF(IMPLICATIONS, "Considering implication of $O for $O:\n",
            wo, for_wo);
    }
    for (imp = wo->implies; imp; imp = imp->next_implication) {
        int f = TRUE, changed_state = TRUE;
        property_name *then_prop = pn_get_property(imp->then_pn);
        possession_marker *pom;
        if (then_prop == NULL) continue;
        if (imp->if_spec == NULL) internal_error("implication without premiss");
        if (pn_int_annotation(imp->then_pn, negated_boolean_ANNOT))
            changed_state = FALSE;
        if (imp->implied_likelihood < 0) changed_state = 1 - changed_state;
        LOGIF(IMPLICATIONS, "$S => $T (certainty %d; changed state %d)\n",
            imp->if_spec, imp->then_pn, imp->implied_likelihood, changed_state);
        if (does_object_provide(for_wo, then_prop) == FALSE) {
            LOGIF(IMPLICATIONS, "IMPOSSIBLE: property not provided\n");
            continue;
        }
        pom = prn_get_possession_marker(then_prop);
        LOGIF(IMPLICATIONS, "Possession marker has (certainty %d; possessed state %d)\n",
            pom->possession_certainty, pom->possessed);
        if (pom->possessed == changed_state) {
            LOGIF(IMPLICATIONS, "REDUNDANT: property already correct\n");
            continue;
        }
        if (pom->possession_certainty == CERTAIN_CE) {
            LOGIF(IMPLICATIONS, "IRRELEVANT: property already settled\n");
            continue;
        }
```

```
        adjective_list_entry *ale;
        LOOP_THROUGH_ADJECTIVE_LIST(ale, imp->if_spec) {
            adjectival_phrase *aph = get_adjective_from_list_entry(ale);
            property_name *prn = aph_has_EORP_meaning(aph);
            if (prn == NULL) internal_error("non-EORP adjective in implication");
            pom = prn_get_possession_marker(prn);
            if (pom->possessed == FALSE) f = FALSE;
        }
        if (f) {
            LOGIF(IMPLICATIONS, "PASS: changing property $Y of $O\n", then_prop, for_wo);
            adjectival_phrase *aph = prn_either_or_get_aph(then_prop);
            pcalc_prop *set_prop = atom_unary_PREDICATE_from_aph(aph, FALSE);
            if (changed_state == FALSE) {
                set_prop = prop_concatenate(atom_new(NEGATION_OPEN_ATOM), set_prop);
                set_prop = prop_concatenate(set_prop, atom_new(NEGATION_CLOSE_ATOM));
            }
            int pm = prevailing_mood;
            prevailing_mood = CERTAIN_CE;
            prop_true_in_world_model_about(set_prop, for_wo, NULL);
            prevailing_mood = pm;
            pom = prn_get_possession_marker(then_prop);
            pom->possessed = changed_state;
            pom->possession_certainty = CERTAIN_CE;
            if (prn_either_or_get_negation(then_prop)) {
                pom = prn_get_possession_marker(prn_either_or_get_negation(then_prop));
                pom->possessed = 1-changed_state;
                pom->possession_certainty = CERTAIN_CE;
            }
        } else {
            LOGIF(IMPLICATIONS, "FAIL: take no action\n");
        }
    }
}
```

§**3.** We begin by checking implications associated with X and applying to X, but in fact because the routine above recurses depth-first through the kinds, a typical object X – a container, say – will first have implications associated with "thing" applied to it, then with those associated with "container", and only then its own implications.

```
void consider_implications(world_object *wo) {
    property_name *prn;
    if (wo->kind_flag) return;
    LOOP_OVER(prn, property_name) {
        possession_marker *pom = prn_get_possession_marker(prn);
        pom->possessed = FALSE;
        pom->possession_certainty = UNKNOWN_CE;
    }
    set_possessed_flags(wo);
    LOGIF(IMPLICATIONS, "Started implications about $O\n", wo);
    check_implications_of(wo, wo);
    LOGIF(IMPLICATIONS, "Finished implications about $O\n", wo);
}
```

The function consider_implications is called from 9/model.

9 Inference and Model

`9/rsdt`: *Runtime Support for Data Types.w* To compile I6 material needed at runtime to enable data types to function as they should.

`9/qty`: *Quantities.w* To manage initial and current values of named values, which may be either constants or variables, but which have global scope.

`9/scene`: *Scenes.w* Scenes are periods of time during play: at any given moment, several may be going on, or none. They are started and stopped when certain conditions are met, or by virtue of having been anchored together.

`9/wo`: *World Objects.w* Who is World, I hear you cry, and to what does he object? Just my little joke. This section contains code to create, uncreate and parse the names of world objects, which are objects or kinds of objects used in the model of the physical world.

`9/kind`: *Kinds.w* To manage kinds of world object, which are analogous to classes in the sense of Inform 6.

`9/spabp`: *Spatial Relations.w* To define the binary predicates corresponding to basic spatial relationships such as containment, support and being part of.

`9/mapbp`: *Map Connection Relations.w* To define one binary predicate for each map direction, such as "mapped north of".

`9/exrel`: *Explicit Relations.w* To draw inferences from the relations created explicitly by the source text.

`9/prop`: *Properties.w* World objects and kinds have "properties" associated with them. Some are either/or, while others hold values: a value-property always has a kind of value it must hold, and type-checking is used to ensure that it always does hold that kind of value. (Inform does not have a boolean type: so an either/or property is not a value property whose value is required to be of boolean type.) In this section of code, we consider "property names" – the properties, such as "open" or "carrying capacity", rather than knowledge about their values in the case of individual objects.

`9/pp`: *Property Permissions.w* To enforce the domain of properties: for instance, that a door can be open or closed but that an animal cannot, or that a person can have a carrying capacity but that a door cannot.

`9/provr`: *The Provision Relation.w* To define the provision relation, which determines which properties can be held by which objects.

`9/madj`: *Measurement Adjectives.w* To define adjectives such as large, wide or roomy, which make implicit comparisons of the size of some numerical property, and which (unlike other adjectives) lead to comparative and superlative forms.

`9/cmpbp`: *Comparative Relations.w* When a measurement adjective like "tall" is defined, so is a comparative relation like "taller".

`9/vpbp`: *Value-Property Relations.w* Each value property has two associated relations, one to set the value for a single holder and the other to compare its value between two holders.

`9/inf`: *Inferences.w* To manage the individual pieces of information gathered, with varying degrees of certainty, from assertion sentences. This is mostly information about which objects have what properties.

`9/model`: *Make Model World.w* Once the assertions have all been read and reduced to inferences, and all the world objects are created, we then have to work out their likely kinds. Mostly this is

easy: if we were told that X is on Y, for instance, we can immediately see that Y needs to be a supporter. But we go through a fairly thorough process in order to make sure that every piece of information is considered, even in easy cases, so that any contradiction is caught and reported back. "Creating a program often means that you have to create a small universe" (Donald Knuth).

`9/cot`: *Compile Object Tree.w* To write out the I6 object or class schemas as needed, looking through the inferences as needed to find the property values required, and to declare the objects in foundational order, as I6 (unlike I7) requires.

`9/inpw`: *Index Physical World.w* To index the kind hierarchy and the object tree.

`9/map`: *Spatial Map.w* To fit the map of the rooms in the game into a cubical grid, preserving distances and angles where possible, and then render it as HTML using a grid of icons for the World Index and also as an EPS file.

`9/tmap`: *Temporal Map.w* Parallel to the World index of space is the Scenes index of time, and in this section we render it as HTML.

Quantities 9/qty

Purpose

To manage initial and current values of named values, which may be either constants or variables, but which have global scope.

9/qty.§8 Parsing quantity names; §9 List of quantities in the Contents index; §10-11 Quantity compilation; §12 Scenes as quantities

---

Template interpreter commands

```
9   {-callv:index_quantities}
11  {-callv:declare_quantities}
11  {-array:Global_Vars}
```

Definitions

¶1. Quantities are named values: some are constants, some are variables, but all have more than temporary scope. (So, for instance, local variables are not stored as quantities.) In the text

> The colours are red, blue and green. The score to beat is a number that varies.

four quantities are created: "red", "blue" and "green", which are constants of type "colour" made to differ from all other known "colour" values (including each other), and "score to beat", which is a variable of type "number".

"Library defined" quantities are those which give NI names to constants or global variables created within the I6 library, like `score` or `location`.

```
typedef struct quantity {
    int word_ref1, word_ref2;                          text of the name
    struct parse_node *quantity_created_at;            sentence creating the quantity
    struct parse_node *initialised_at;                 where an initial value was given
    int q_documentation_symbol_wn;                     reference to manual, if any
    int is_a_variable;                                 rather than a constant
    struct specification *initial_value;               initial value (vars) or value (consts)
    int adjectivally_used;                             constant value used as an adjective, like "red"?
    struct adjectival_phrase *usage_as_aph;            if so, what adjective
    struct stacked_variable *is_a_stv;                 its identity as a STV (if any)
    struct inference *knowledge_about_constant;        if a constant
    struct kind_of_value *quantity_kov;                i.e., the data type for the variable
    int externally_defined;                            declared by I6 code already, e.g. by I6 library
    int index_in_i6_table;                             or -1 if not stored in a table
    char qty_I6_identifier[32];                        an I6 identifier
    MEMORY_MANAGEMENT
} quantity;
```

The structure quantity is private to this section.

¶2. Five more miscellaneous quantities (besides the ones treated in Bibliographic Data, that is): the initial time of day, the maximum score, "the player" – which needs special handling because Inform users believe it to be a constant, when in fact it is a variable; and a quantity to hold the I6 variable `subst__v`, used in the substitution of an object-loop variable into unbound object specifications. `i6_nothing_quantity` is by contrast a constant: it compiles to `nothing`, which in I6 is zero, but for type-checking reasons is distinguished from the number 0.

```
quantity *time_of_day_quantity = NULL;
quantity *max_score_quantity = NULL;
quantity *player_quantity = NULL;
quantity *i6_nothing_quantity = NULL;
quantity *subst_variable_quantity = NULL;                    I6 subst__v, substituted into objspecs
quantity *real_location_quantity = NULL;
quantity *actor_location_quantity = NULL;
quantity *parameter_object_quantity = NULL;
quantity *i6_glob_quantity = NULL;
quantity *I6_noun_quantity = NULL;
quantity *I6_second_quantity = NULL;
quantity *I6_actor_quantity = NULL;
```

¶3. We record the one most recently made:

```
quantity *latest_quantity = NULL;
```

---

§**1.** Some quantities can be used adjectivally, but not others. This happens when the type name coincides with a name for a property held by a world object, as might for instance happen with "colour". In other words, because it is reasonable that a ball might have a colour, we can declare that "the ball is green", or speak of "something blue": whereas we are not allowed to use "score to beat" adjectivally since (a) it is a variable, and (b) "number" is not a coinciding property: we would not ordinarily write "the ball is 4". (A quirk in English would allow this for children, say, by construing number as an age property belonging to the child in question. But we don't go there in NI.)

Therefore some quantities are entered twice into the dictionary of excerpt meanings, once in the context of nouns, once as adjectives. The following routine does the necessary supplementary work for any quantity established as possibly adjectival.

```
adjective_meaning *ENUMERATIVE_KADJ_parse(parse_node *q,
    int sense,
    int adj_name_w1, int adj_name_w2,
    int dom_name_w1, int dom_name_w2,
    int cond_w1, int cond_w2,
    int called_w1, int called_w2) {
    return NULL;
}

void ENUMERATIVE_KADJ_compiling_soon(adjective_meaning *am, quantity *q, int T) {
}

int ENUMERATIVE_KADJ_compile(quantity *q, int T, OUTPUT_STREAM, ph_stack_frame *phsf) {
    return FALSE;
}

int ENUMERATIVE_KADJ_assert(quantity *q,
```

```
    world_object *wo_to_assert_on, specification *val_to_assert_on, int parity) {
    inference_subject infs;
    if (parity == FALSE) return FALSE;
    if (wo_to_assert_on) infs = inference_subject_wo(wo_to_assert_on);
    else infs = inference_subject_spec(val_to_assert_on);
    property_name *prn = kov_get_coinciding_property(q->quantity_kov);
    if (prn == NULL) internal_error("enumerative adjective on non-property");
    inference *i = create_property_inference(infs, prn, q->initial_value);
    join_inference(i, infs);
    return TRUE;
}

int ENUMERATIVE_KADJ_index(quantity *q) {
    property_name *prn = kov_get_coinciding_property(q->quantity_kov);
    if (prn_condition_of_which_object(prn) == FALSE) {
        property_permission *pp = prn_permission_list(prn);
        if (pp) { INDEX("(of "); pp_index_applicabilities(pp); INDEX(") "); }
        INDEX("having this ");
        print_raw_text_to_file(prn->word_ref1, prn->word_ref2, ifl);
    } else {
        quantity *q2;
        int nq = 0, i = 0;
        INDEX("a condition which is otherwise ");
        LOOP_OVER(q2, quantity)
            if ((q2 != q) &&
                (q2->is_a_variable == FALSE) &&
                (kov_compare(q2->quantity_kov, q->quantity_kov))) nq++;
        LOOP_OVER(q2, quantity)
            if ((q2 != q) &&
                (q2->is_a_variable == FALSE) &&
                (kov_compare(q2->quantity_kov, q->quantity_kov))) {
                i++;
                INDEX("</i>");
                print_raw_text_to_file(q2->word_ref1, q2->word_ref2, ifl);
                INDEX("<i>");
                if (i == nq-1) INDEX(" or ");
                else if (i < nq) INDEX(", ");
            }
    }
    return TRUE;
}
```

The function ENUMERATIVE_KADJ_parse is called from 5/aph.

The function ENUMERATIVE_KADJ_compile is called from 5/aph.
The function ENUMERATIVE_KADJ_assert is called from 5/aph.
The function ENUMERATIVE_KADJ_index is called from 5/aph.

§2.

```
void register_as_adjectival_quantity(quantity *q, property_name *prn) {
    LOGIF(QUANTITY_COMPILATION, "RACQ on $W property $Y (%d)\n",
        q->word_ref1, q->word_ref2, prn, spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA));
    pp_register_as_adjectival(q, prn);
}
void register_as_adjectival_quantity_domain(quantity *q, property_name *prn,
    kind_of_value *domain_kov, world_object *domain_wo) {
    if (qty_is_a_variable(q) == FALSE) {
        if (domain_kov == NULL) {
            if (q->adjectivally_used) return;
            q->adjectivally_used = TRUE;
        }
        LOGIF(QUANTITY_COMPILATION, "RACQ on $W property $Y (%d), WO=$O, KOV=$u\n",
            q->word_ref1, q->word_ref2, prn, spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA),
domain_wo,
            domain_kov);
        if (domain_kov)
        LOGIF(QUANTITY_COMPILATION, "RACQ sees range %d, offset %d in ID %d\n",
            pp_get_prn_offset_in_kov(NULL, domain_kov),
            pp_get_prn_offset_in_kov(prn, domain_kov),
            kov_I6_ID(domain_kov));
        adjective_meaning *am = am_new(ENUMERATIVE_KADJ, STORE_POINTER_quantity(q),
            q->word_ref1, q->word_ref2);
        q->usage_as_aph = am_declare(am, q->word_ref1, q->word_ref2);
        if (domain_wo)
            am_set_domain_from_wo(am, domain_wo);
        else if (domain_kov)
            am_set_domain_from_kov(am, domain_kov);
        else
            am_set_domain_from_wo(am, NULL);
        i6_schema *sch = am_set_i6_schema(am, TEST_ADJECTIVE_TASK, FALSE);
        if (domain_kov)
        sch_write_to_existing_3d(sch,
            "PropertyKOV(KOVP_%d,%d,*1) == %d",
                kov_I6_ID(domain_kov),
                pp_get_prn_offset_in_kov(prn, domain_kov),
                spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA));
        else
        sch_write_to_existing_1s1d(sch,
            "ValueProperty(*1,%s) == %d", prn_get_i6_identifier(prn),
                spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA));
        sch = am_set_i6_schema(am, NOW_ADJECTIVE_TRUE_TASK, FALSE);
        if (domain_kov)
        sch_write_to_existing_3d(sch,
            "WritePropertyKOV(KOVP_%d,%d,*1,%d)",
                kov_I6_ID(domain_kov),
                pp_get_prn_offset_in_kov(prn, domain_kov),
                spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA));
        else
        sch_write_to_existing_1s1d(sch,
            "WriteValueProperty(*1,%s,%d)", prn_get_i6_identifier(prn),
```

```
                spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA));
    }
}
```

The function register_as_adjectival_quantity_domain is called from 9/pp.

§**3.** And this is the routine with the power to make a property and a type name coincide:

```
void make_type_coincident(kind_of_value *kov, property_name *pn) {
    kov_set_coinciding_property(kov, pn);
    update_adjectival_forms(pn);
}

void update_adjectival_forms(property_name *pn) {
    if (prn_is_either_or(pn) == TRUE) return;
    kind_of_value *kov = prn_get_kind_of_value(pn);
    if (pn == kov_get_coinciding_property(kov)) {
        quantity *q;
        LOOP_OVER(q, quantity)
            if (kov_compare(q->quantity_kov, kov))
                register_as_adjectival_quantity(q, pn);
    }
}
```

The function make_type_coincident is called from 7/data and 9/prop.
The function update_adjectival_forms is called from 9/pp.

§**4.** With those defined, here is the routine which creates a new quantity and decides what name it should have in the I6 source code.

NI is a typed language but I6 is not. The quantities "number understood", "time understood", etc., really all represent the same thing – the value which was parsed in a command at run-time – but they are all distinct NI quantities because they need to have different types. In I6 they revert to being all the same variable `parsed_number`.

The other complications in this routine are to set a dozen or so global
(NI) variables to the quantities created with particular names – they are created, mostly, in the Standard Rules; to give some quantities specific I6 names defined in the I6 library, while letting others have mechanically generated new I6 names; and to notify the scene machinery when a new scene constant is created. (To create a constant scene is to create an actual scene.)

```
int no_i6_table_entries_used = 0;

quantity *new_model_quantity(int w1, int w2, kind_of_value *kov, int varies) {
    PROTECTED_MODEL_PROCEDURE;
    return new_quantity(w1, w2, kov, varies, NULL);

The function qty_get_value_index is called from 9/cot.

§**7.** Actually compiling a valid I6 expression for a given quantity is now fairly easy.

```
void compile_quantity_name(OUTPUT_STREAM, quantity *q) {
    if (q->index_in_i6_table >= 0)
        WRITE("(Global_Vars-->%d)", q->index_in_i6_table);
    else
        WRITE("%s", q->qty_I6_identifier);
}
void compile_quantity_name_to_string(OUTPUT_STREAM, quantity *q) {
    if (q->is_a_stv)
        stv_compile_lvalue(OUT, q->is_a_stv);
    else {
        if (q->index_in_i6_table >= 0)
            WRITE("(Global_Vars-->%d)", q->index_in_i6_table);
        else
            WRITE("%s", q->qty_I6_identifier);
    }
}
```

The function compile_quantity_name is called from 9/rsdt and 13/gprv.
The function compile_quantity_name_to_string is called from 7/vasp and 7/stsp.

§8. Parsing quantity names.

```
quantity *qty_parse(int w1, int w2) {
    meaning_list *ml;
    [[w1, w2 == the ... --> w1, w2]];
    ml = SP_excerpt(QUANTITY_MC, w1, w2);
    if (ml) return RETRIEVE_POINTER_quantity(em_data(ml_meaning(ml)));
    return NULL;
}
```

The function qty_parse is called from 8/mass.

§9. List of quantities in the Contents index. The following is part of the Contents index, and acts as an aide-memoire of the names of the variable quantities created in the source text.

```
void index_quantities(void) {
    quantity *q;
    heading *definition_area, *current_area = NULL;
    INDEX("<p><hr><p>");
    index_anchor("NAMES");
    INDEX("<b>List of named values</b> (<i>About these</i>");
    index_doc_link("VARIABLES"); INDEX(")<p>\n");
    LOOP_OVER(q, quantity)
        if ((qty_is_a_variable(q)) && (q->word_ref1 >= 0) && (q->is_a_stv == NULL)) {
            definition_area =
                heading_of(lw_array[q->word_ref1].lw_source);
            if (hd_indexed(definition_area) == FALSE) continue;
            if (definition_area != current_area) {
                int x1, x2, j;
                hd_get_text_of_heading(definition_area, &x1, &x2);
                INDEX("<p>");
                if ((x1 >= 0) && ((j = is_word_intermediate(HYPHEN_V, x1, x2))>=0)) {
                    x1 = j+1;
                    INDEX("<b>");
                    print_raw_text_to_file(x1, x2, ifl);
                    INDEX("</b><br>");
                }
            }
            current_area = definition_area;
            qty_index_single(q);
        }
}

void qty_index_single(quantity *q) {
    print_raw_text_to_file(q->word_ref1, q->word_ref2, ifl);
    index_link(lw_array[q->word_ref1].lw_source);
    if (q->q_documentation_symbol_wn >= 0) {
        index_doc_link(lw_array[q->q_documentation_symbol_wn].lw_rawtext);
    }
    INDEX(" ... <i>");
    index_lowercase_kov(q->quantity_kov);
```

```
    INDEX("</i><br>\n");
}

world_object *qty_initial_value(quantity *q) {
    if (q == NULL) return NULL;
    return wo_of_CONSTANT_OBJECT_if_any(q->initial_value);
}
```

The function index_quantities is invoked by a command in a `.i6t` template file.
The function qty_index_single is called from 12/stv.
The function qty_initial_value is called from 9/cot.

§**10. Quantity compilation.** The following routine compiles the correct initial value for the given quantity. If it has no known initial value, it is given the initial value for its type where possible: note that this may not be possible if the source text says something like

> Thickness is a kind of value. The carpet nap is a thickness that varies.

without specifying any thicknesses: the set of legal thickness values is empty, so the carpet nap variable cannot be created in a way which makes its type safe. Hence the error messages.

```
void compile_quantity_initial(OUTPUT_STREAM, quantity *q) {
    TEMPORARY_STREAM;
    LOGIF(QUANTITY_COMPILATION,
        "Compiling initial value of quantity: $Q\n"
        "From initial value $S\n", q, q->initial_value);
    compile_quantity_initial_inner(TEMP, q);
    STREAM_COPY(OUT, TEMP);
    CLOSE_TEMPORARY_STREAM;
}

    }
}
```

The function declare_quantities is invoked by a command in a `.i6t` template file.

The function compile_Global_Vars_array is invoked by a command in a `.i6t` template file.

§**12. Scenes as quantities.** When a new scene is created, with text such as "Train Stop is a scene.", what actually happens is that a constant quantity ("Train Stop") is created, whose kind of value is `SCENE`. The following routines place a scene pointer into, or extract one from, a quantity.

```
void write_scene_to_quantity(quantity *q, scene *sc) {
    int ix = spec_get_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA);
    q->quantity_kov = kova(SCENE_TY);
    q->initial_value = scene_to_SCENE_spec(sc);
    spec_set_data(q->initial_value, QUANTITY_ENUMERATION_SPDATA, ix);
}

scene *read_scene_from_quantity(quantity *q) {
    if (is_kova(q->quantity_kov, SCENE_TY) == FALSE)
        internal_error("tried to find scene from non-scenic quantity");
    return SCENE_spec_to_scene(q->initial_value);
}

int qty_is_a_scene_name(quantity *q) {
    if (is_kova(q->quantity_kov, SCENE_TY)) return TRUE;
    return FALSE;
}
```

The function write_scene_to_quantity is called from 9/scene.

The function read_scene_from_quantity is called from 9/scene and 12/phrcd.

The function qty_is_a_scene_name is called from 9/scene, 12/phud and 12/phrcd.

Scenes 9/scene

Purpose

Scenes are periods of time during play: at any given moment, several may be going on, or none. They are started and stopped when certain conditions are met, or by virtue of having been anchored together.

9/scene.§3 Anchors; §4 Run-time storage for scenes; §5 Scene-changing machinery at run-time

Template interpreter commands

```
5   {-routine:DetectSceneChange}
5   {-routine:PrintSceneName}
5   {-routine:ShowSceneStatus}
5   {-array:scene_recurs}
```

Definitions

¶1. Scenes are gated intervals of time, but there are more than two gates: for while there is only one past, there are many possible futures. These gates are called "ends" in the code below, and are numbered end 0 (the beginning), end 1 (the usual end), and then any named ends ("ends badly" or "ends triumphantly", for instance, might be ends 2 and 3). Each end has a condition which can cause it, or can be "anchored" to any number of ends of other scenes – to express which, the `scene_connector` structure is used.

define `MAX_SCENE_ENDS 32`

```
typedef struct scene_connector {
    struct scene *connect_to;                                   scene connected to
    int end;                                                    end number
    struct scene_connector *next;                               next in list of connectors for a scene end
    struct parse_node *where_said;                              where this linkage was specified in source
} scene_connector;

typedef struct scene {
    struct quantity *q;                                         the constant for the name of the scene
    int once_only;                                              cannot repeat during play
    int start_of_play;                                          if begins when play begins
    int marker;
    int no_ends;                                                how many ends the scene has
    int end_names_w1[MAX_SCENE_ENDS];                           for ends 2, 3, ...: e.g. "badly"
    int end_names_w2[MAX_SCENE_ENDS];
    struct rulebook *end_rulebook[MAX_SCENE_ENDS];              rules to apply then
    struct specification *anchor_condition[MAX_SCENE_ENDS];
    struct scene_connector *anchor_scene[MAX_SCENE_ENDS];       linked list
    int indexed;                                  temporary storage during Scenes index creation
    struct parse_node *scene_declared_at;                       where defined
    struct parse_node *anchor_condition_set[MAX_SCENE_ENDS];    where set
    MEMORY_MANAGEMENT
} scene;
```

The structure scene_connector is shared with 9/tmap.
The structure scene is shared with 9/tmap.

---

§**1.** Each scene ending has its own rulebook, and this is where they are created.

```
void new_scene_rulebook(scene *sc, int end) {
    int wn = lexer_wordcount;
    feed_into_lexer("when", TRUE, FALSE);
    splice_words(sc->q->word_ref1, sc->q->word_ref2);
    feed_into_lexer((end==0)?"begins":"ends", TRUE, FALSE);
    if (end >= 2) splice_words(sc->end_names_w1[end], sc->end_names_w2[end]);
    sc->end_rulebook[end] =
        rb_new_automatic(wn, lexer_wordcount-1, ACTION_FOCUS,
            NO_OUTCOME, FALSE, FALSE, FALSE);
    wn = lexer_wordcount;
    feed_into_lexer("when the ", TRUE, FALSE);
    splice_words(sc->q->word_ref1, sc->q->word_ref2);
    feed_into_lexer((end==0)?"begins":"ends", TRUE, FALSE);
    if (end >= 2) splice_words(sc->end_names_w1[end], sc->end_names_w2[end]);
    register_excerpt_meaning(RULEBOOK_MC, 0, wn, lexer_wordcount-1,
        STORE_POINTER_rulebook(sc->end_rulebook[end]));
    rb_set_alt_name(sc->end_rulebook[end], wn, lexer_wordcount-1);
    if (end >= 2) {
        char i6_code[128];
        wn = lexer_wordcount;
        feed_into_lexer("To decide if ", TRUE, FALSE);
        splice_words(sc->q->word_ref1, sc->q->word_ref2);
        feed_into_lexer(" ended ", TRUE, FALSE);
        splice_words(sc->end_names_w1[end], sc->end_names_w2[end]);
        make_sentence_node(wn, lexer_wordcount-1, ':');
        wn = lexer_wordcount;
        sprintf(i6_code, " (- (scene_latest_ending-->%d == %d) -) ",
            sc->allocation_id, end);
        feed_into_lexer(i6_code, TRUE, FALSE);
        make_sentence_node(wn, lexer_wordcount-1, '.');
        wn = lexer_wordcount;
        feed_into_lexer("To decide if ", TRUE, FALSE);
        splice_words(sc->q->word_ref1, sc->q->word_ref2);
        feed_into_lexer(" did not end ", TRUE, FALSE);
        splice_words(sc->end_names_w1[end], sc->end_names_w2[end]);
        make_sentence_node(wn, lexer_wordcount-1, ':');
        wn = lexer_wordcount;
        sprintf(i6_code, " (- (scene_latest_ending-->%d ~= 0 or %d) -) ",
            sc->allocation_id, end);
        feed_into_lexer(i6_code, TRUE, FALSE);
        make_sentence_node(wn, lexer_wordcount-1, '.');
        register_recently_lexed_phrases();
    }
}
```

§**2.** The following routine is so named because it is called by the quantity-maker. In effect, the quantities code notifies us of the creation of a new `SCENE` constant: we take it from there.

```
void new_scene_made(quantity *q, int modifiers) {
    int end;
    scene *sc = CREATE(scene);
    sc->q = q;
    sc->once_only = TRUE; if (modifiers & 1) sc->once_only = FALSE;
    sc->indexed = FALSE;
    sc->no_ends = 2;
    sc->start_of_play = FALSE;
    sc->scene_declared_at = current_sentence;
    for (end=0; end<2; end++) {
        sc->anchor_condition[end] = NULL;
        sc->anchor_scene[end] = NULL;
    }
    write_scene_to_quantity(q, sc);
    new_scene_rulebook(sc, 0);
    new_scene_rulebook(sc, 1);
}

quantity *scene_quantity(scene *sc) {
    if (sc == NULL) return NULL;
    return sc->q;
}
```

The function new_scene_made is called from 9/qty.
The function scene_quantity is called from 7/specv.

§**3. Anchors.** These are joins between the endings of different scenes. Any end of any scene can be anchored to any end of any scene (including itself).

```

```

§**4. Run-time storage for scenes.** At run-time, we need to store information about the current state of each scene: whether it is currently playing or not, when the last change occurred, and so on. This data is stored in I6 arrays as follows.

First, each scene has a unique ID number, used as an index `X` to these arrays. This ID number is what is stored as an I6 value for the kind of value `scene`, and it agrees with the allocation ID for the I7 scene structure.

`scene_status-->X` is 0 if the scene is not playing, but may do so in future; 1 if the scene is playing; or 2 if the scene is not playing and will never play again.

`scene_started-->X` is the value of `the_time` when the scene last started, or 0 if it has never started.

`scene_ended-->X` is the value of `the_time` when the scene last ended, or 0 if it has never ended. (The "starting" end does not count as ending for this purpose.)

`scene_endings-->X` is a bitmap recording which ends have been used, including bit 1 which records whether the scene has started.

`scene_latest_ending-->X` holds the end number of the most recent ending (or 0 if the scene has never ended).

§**5. Scene-changing machinery at run-time.** We now compile an I6 routine, `DetectSceneChange`, which detects scene changes and runs the appropriate rulebooks when they occur. ■

```
void compile_scene_end_dash(OUTPUT_STREAM, scene *sc, int end) {
    int skip_rules = FALSE;
    if (end == -1) { end = 1; skip_rules = TRUE; }

World Objects 9/wo

Purpose

Who is World, I hear you cry, and to what does he object? Just my little joke. This section contains code to create, uncreate and parse the names of world objects, which are objects or kinds of objects used in the model of the physical world.

9/wo.¶3-0 Special world objects; §2 Access to details; §3 Namelessness; §4-6 Parsing names of world objects; §7 The debugging of knowledge

---

Definitions

¶1. At this point, we have essentially disposed of the original source text altogether. As we read it in, we converted it to a set of distinct objects, together with properties which they might or might not have. For each object, a list of inferences was drawn up about its spatial relationship to other objects, the values of its properties, and so on. Although we rejected obvious contradictions and discarded redundancies as we went, we never compared the knowledge about one object with the knowledge about another, and nor did we have to take "what is the most likely thing to have been meant?" decisions. In this chapter, we have to get from that collection of knowledge to a specific and explicit model of the world, in the form of a set of I6 object, class, property and attribute declarations which we can be certain will compile under I6 without error.

Other, more abstract, things were also created from time to time in the assertions-maker, in particular variables and tables: those are deferred to the next chapter.

¶2. A world object is a physical thing, room, direction or region, or a kind of any of those. We think of it as part of the model world, in a way that a kind of value is not.

World objects are originally created during assertion parsing, when sentences like "A quick brown fox is in the undergrowth" are read. At this stage, the data structure below is only very sketchily filled in, and indeed might never be finished. Because the assertion-maker sometimes jumps the gun by creating objects too soon, we also need the ability to destroy them again if it turned out that the initially plausible source text did not refer to something physical after all.

Later, when all assertions have been turned into inferences, the known facts are weighed to work out the spatial relationships between world objects, and also to finish off deciding what kinds they have. The world objects are then assembled in an object tree in the usual interactive fiction manner, and compiled into I6 object or class directives.

At this point, NI is usually only about half done in compiling a source text (all the phrases and rules must still be made), and the data structure goes on being useful. It contains very many fields used temporarily in different contexts, and consumes a good deal of storage per object, but there are too few objects to make any drastic economies meaningful.

```
typedef struct world_object {
    int word_ref1, word_ref2;                          my name, if I have one
    struct parse_node *creating_sentence;              under which assertion sentence
    struct heading *under_what_heading;                in turn under what heading
    struct world_object *next_under_heading;           next in the list under that
    struct parse_node *creator_plural;                 where plural name specified, if it was
    struct excerpt_meaning *principal_meaning;         main singular excerpt meaning this
    struct generalisation *generalisation_list;        assembly instructions, if any
    int currently_making_instance;
    int propername;                                    has a proper name, such as "Jane"
```

```
int pluralname;                                    has a plural name, such as "marbles"
int article_is_the;                                uses "the" as its indefinite article
struct world_object *named_after;                  name derived from another: e.g. "Jane's nose"
int named_after_w1, named_after_w2;                text of the derived part, e.g. "nose"
int nameless;                                      source text name not to be used for parsing at run-time

struct grammar_verb *understand_as_this_object;    grammar for parsing the name at run-time

int search_score;                                  used when searching world objects to parse names in NI
struct world_object *next_to_search;               similarly

struct world_object *kind;                         what kind of object am I?
struct parse_node *kind_set_at;                    and where in the parse tree does it say?
int room_flag;                                     am I a room?
int door_flag;                                     am I a door?
int kind_flag;                                     am I myself a kind?
int instance_count;                                if so, how many instances do I have? (used in indexing)
int instance_list_length;                          and how long is my optimised loop list? (if any)
char *wo_documentation_symbol;                     where I am documented in the manual (if I am)

struct inference *knowledge;                       list of inferences: what is contingently true
struct implication *implies;                       list of implications: what is necessarily true
struct specification *quoted_appearance;           quoted text describing me
struct parse_node *quoted_appearance_sentence;     where it was
int initially_carried;                             am I initially carried by the player character?
int defines_printed_name;                          does the source specify my "printed name"?
int defines_plural_name;                           does the source specify my "printed plural name"?
int defines_description;                           does the source specify my "description"?

struct world_object *object_tree_parent;           in/on/worn by/carried by tree structure
struct world_object *object_tree_child;
struct world_object *object_tree_sibling;
struct world_object *part_of;                      part-of tree structure
struct world_object *first_part;
struct world_object *next_part;
struct world_object *in_region;                    smallest region containing me (rooms only)
int here_flag;                                     declared simply as being "here"

struct world_object *next_in_I6_order;             linked list in order of declaration in I6
int I6_definition_depth;                           i.e., how many arrows -> appear in its I6 header

struct world_object *map_connection_a;             temporary: used to place doors
struct world_object *map_connection_b;
struct world_object *map_connection_c;
struct world_object *map_direction_a;
struct world_object *map_direction_b;
struct world_object *map_direction_c;

int index_appearances;                             count of mentions in the World index
char *world_index_description;                     notations such as "carried" or "part"
int rough_array_memory_used;                       in words, not bytes; for kinds only

int direction_index;                               directions only: counts 0, 1, 2, ..., in order of creation
struct world_object *exits[MAX_DIRECTIONS];        temporary: for World index (rooms only)
int lock_exit;
struct world_object *lock_exit_to;
int grid_x, grid_y, grid_z;
struct map_component *component;
char *world_index_colour;                          an HTML colour for the room square (rooms only)

struct map_parameter_scope local_map_parameters;   temporary: used in EPS mapping
```

```
    int eps_x, eps_y;
    char wo_I6_identifier[32];                    Name to be used in Inform 6 output
    char direction_property[32];
    int rightc, leftc;                            temporary: used in constructing relation arrays
    int relation_indices[2];
    struct inference *right_infs[2];
    struct kind_of_value *kovko_of_this;          cached result of kovko(W)
    MEMORY_MANAGEMENT
} world_object;
```

The structure world_object is shared with 2/index, 2/lexi, 2/prob2, 2/prob3, 4/edoc, 4/head, 5/rel, 5/conj, 5/aph, 5/parse, 5/mlc, 6/asp, 7/kov, 7/kix, 7/vasp, 7/stsp, 7/cosp, 7/tc, 8/sob, 8/refpt, 8/creat, 8/mass, 8/assem, 8/knowc, 8/relv, 8/imp, 9/kind, 9/spabp, 9/pp, 9/inf, 9/model, 9/cot, 9/inpw, 9/map, 10/list, 10/tab, 11/ap, 13/gv and 13/gpr.

¶3. Special world objects. One room is special in being where play begins, one object as being where the player starts (not necessarily a room: it might be, say, a barber's chair inside a room) and a third object as being the player character, the one with printed name `"yourself"`:

```
world_object *start_room = NULL;
world_object *start_object = NULL;
world_object *wo_yourself = NULL;
world_object *wo_up_direction = NULL;
world_object *wo_down_direction = NULL;
```

---

§**1.** World object creation is complicated by two factors: first, that all world objects are stored in a linked "search list" giving the priority of name-searching when parsing text – a complication because each object creation means having to update this list; and second, world objects are frequently brought into being only for a short time before being destroyed again.

Note that we require the first 10 kinds created to be the right things. That all happens in the Standard Rules: if the Standard Rules ever reorder these kind creations, disaster will ensue. Once these basic kinds are created, we can revise the binary predicate definitions. Some of these BPs contain references saying that their terms must be objects of these basic kinds – but up to now, it has been impossible to use a pointer to the relevant kind in a BP structure, because that kind did not exist. The revision process makes that good.

```
int no_wos_now_existing = 0, no_wo_creations = 0;        different because of deletions
world_object *latest_world_object = NULL;
world_object *get_latest_world_object(void) {

```

The function get_latest_world_object is called from 8/creat.
The function wo_get_no_wos_now_existing is called from 4/head.
The function create_world_object is called from 6/asp.

§2. Access to details.

```
parse_node *wo_get_creating_sentence(world_object *wo) {
    return wo->creating_sentence;
}
char *wo_get_I6_representation(world_object *wo) {
    if (wo == NULL) return "nothing";
    return wo->wo_I6_identifier;
}
void wo_set_I6_representation(world_object *wo, char *new) {
    int i, trim = FALSE;
    char *p = wo->wo_I6_identifier;
    if (*new == '"') { new++; trim = TRUE; }
    for (i=0; (i<31) && (new[i]); i++) p[i] = new[i]; p[i] = 0;
    if ((trim) && (p[0])) p[strlen(p)-1] = 0;
}
excerpt_meaning *wo_get_principal_meaning(world_object *wo) {
    return wo->principal_meaning;
}
```

The function wo_get_I6_representation is called from 5/bp, 5/rel, 5/aph, 6/atoms, 7/kov, 7/vasp, 9/pp, 9/inf, 9/cot, 9/inpw, 11/ap, 12/cinv, 13/gtok, 13/test and 14/i6t.
The function wo_set_I6_representation is called from 9/model.
The function wo_get_principal_meaning is called from 5/ml.

§3. **Namelessness.** This is for objects whose names in the source text won't be compiled into I6 `name` properties, so that they won't ordinarily be referred to by the player at run-time.

```
int wo_is_nameless(world_object *wo) {
    while (wo) {
        if (wo == kind_kind) break;
        if (wo->nameless != NOT_APPLICABLE) return wo->nameless;
        wo = wo->kind;
    }
    return FALSE;
}
```

The function wo_is_nameless is called from 9/cot.

§4. **Parsing names of world objects.** The following routine registers the name, and plural name, of a new object. Note that everything gets a plural name: even something palpably unique, like "the Koh-i-Noor diamond". The plural dictionary supports multiple plurals, so there may be any number of names registered: for instance, the kind "person" is registered with plurals "persons" and "people".

```
void register_wo_names(world_object *new_object, int w1, int w2) {
    plural_dictionary_entry *pde = NULL;
    if [[w1, w2 == yourself]] wo_yourself = new_object;
    if (w1 >= 0) {
        int k = 0;
        new_object->principal_meaning = register_excerpt_meaning(
            WORLD_OBJECT_MC, 0, w1, w2, STORE_POINTER_world_object(new_object));
        new_object->creator_plural = new_node(NOUNPHRASE_NT);
        do {
            k++;
            pde = make_plural_of(w1, w2, pde);
            if (plw1 >= 0) {
                LOGIF(PLURALS, "(%d) Reading plural of <$W> as <$W>\n", k,
                    w1, w2, plw1, plw2);
                if (new_object->creator_plural->word_ref1 == -1) {
                    new_object->creator_plural->word_ref1 = plw1;
                    new_object->creator_plural->word_ref2 = plw2;
                    LOGIF(PLURALS, "(%d) Setting plural of <$W> as <$W>\n", k,
                        w1, w2, plw1, plw2);
                }
                register_excerpt_meaning(
                    WORLD_OBJECT_MC, 0, plw1, plw2,
                    STORE_POINTER_world_object(new_object));
            }
        } while (pde);
    }
}

int wo_has_ING_name(world_object *wo) {
```

```
    int i;
    if ((wo == NULL) || (wo->word_ref1 < 0) || (wo->word_ref1 < 0))
        return FALSE;
    for (i = wo->word_ref1; i <= wo->word_ref2; i++)
        if (vocab_test_flags(i, ING_MC)) return TRUE;
    return FALSE;
}
```

The function register_wo_names is called from 8/creat.
The function wo_has_ING_name is called from 11/ap.

§**5.** Note that some WOs are nameless (those with `creator` null), and not all necessarily have plurals, so the set of world object names by no means corresponds to the set of world objects. The actual parsing is done by a method which will be explained later, but the gist of it is to produce a list of all possible matches.

```
world_object *parse_world_object(int w1, int w2, int kinds_only) {
    meaning_list *ml;
    if (w2<0) w2=w1; if (w1<0) return NULL;
    if (is_a_literal(w1, w2)) return NULL;
    ml = SP_excerpt(WORLD_OBJECT_MC, w1, w2);
    if (ml == NULL) return NULL;
    return disambiguate_world_object(ml, kinds_only);
}
```

The function parse_world_object is called from 5/rel, 5/candd, 8/creat, 9/model, 9/map, 10/tab, 13/tfg, 13/test and 14/i6t.

§**6.** The tricky part is to choose from the aforementioned list of possible world objects intended. If the list is empty or contains only one choice, there is no problem. Otherwise we will probably have to reorder the object search list, and then run through it. The code below looks as if it picks out the match with highest score, so that the ordering is unimportant, but in fact the score assigned to a match is based purely on the number of words missed out (see later): that means that ambiguities often arise between two lexically similar objects, e.g., a "blue chair" or a "red chair" when the text simply specifies "chair". Since the code below accepts the *first* object with the highest score, the outcome is thus determined by which of the blue and red chairs ranks highest in the search list: and that is why the search list is so important.

```
world_object *disambiguate_world_object(meaning_list *ml, int kinds_only) {
    meaning_list *ml2;
    world_object *wo, *best_wo = NULL;
    int best_score = 0;
    if (ml == NULL) return NULL;
    if (ml_sideways(ml) == NULL) {
        wo = RETRIEVE_POINTER_world_object(em_data(ml_meaning(ml)));
        if ((kinds_only == FALSE) || (wo->kind_flag)) return wo;
        return NULL;
    }
    construct_wo_search_list();
    LOOP_OVER_WO_SEARCH_LIST(wo) wo->search_score = 0;
    for (ml2 = ml; ml2; ml2 = ml_sideways(ml2)) {
        wo = RETRIEVE_POINTER_world_object(em_data(ml_meaning(ml2)));
        if ((kinds_only == FALSE) || (wo->kind_flag))
```

```
            wo->search_score = ml_match_score(ml2);
    }
    LOOP_OVER_WO_SEARCH_LIST(wo)
        if ((wo->search_score > 0) && (wo->search_score > best_score)) {
            best_wo = wo;
            best_score = wo->search_score;
        }
    return best_wo;
}
```

The function disambiguate_world_object is called from 5/mlc.

§7. The debugging of knowledge.

```
void log_world_object(world_object *wo) {
    if (wo == NULL) { LOG("<null>"); return; }
    if (logging_to_I6_text == FALSE) {
        if (wo->kind_flag) LOG("K"); else LOG("O");
        LOG("%d", wo->allocation_id);
    }
    if (wo->word_ref1 >= 0) {
        LOG("'");
        if (wo->word_ref1 < 0) LOG("<nameless creator>");
        else {
            int i;
            for (i=wo->word_ref1; i<=wo->word_ref2; i++) {
                LOG("%s", lw_array[i].lw_text);
                if (i < wo->word_ref2) LOG(" ");
            }
        }
        LOG("'");
    }
}
void log_knowledge_about_object(world_object *wo) {
    LOG("$O (parent $O)", wo, wo->object_tree_parent);
    if (wo->creator_plural)
        LOG(" (plural $W)", wo->creator_plural->word_ref1, wo->creator_plural->word_ref2);
    LOG("\n");
    if (wo->kind) LOG("  Kind: $O\n", wo->kind);
    if (wo->knowledge) {
        inference *in;
        LOG("  Inferences:\n");
        for (in = wo->knowledge; in; in = in->next) LOG("    $I\n", in);
    }
}
void log_object_tree(void) {
    world_object *wo;
    LOOP_OVER(wo, world_object)
        if (wo->object_tree_parent == NULL)
            log_object_tree_recursively(wo, 0);
}
void log_object_tree_recursively(world_object *wo, int depth) {
```

```
    int i = depth;
    while (i>0) { LOG("  "); i--; }
    LOG("$O\n", wo);
    if (wo->object_tree_child)
        log_object_tree_recursively(wo->object_tree_child, depth+1);
    if (wo->object_tree_sibling)
        log_object_tree_recursively(wo->object_tree_sibling, depth);
}
```

The function log_world_object is called from 2/dl and 9/model.
The function log_knowledge_about_object is called from 2/prob3.
The function log_object_tree is called from 9/model.

Kinds 9/kind

Purpose

To manage kinds of world object, which are analogous to classes in the sense of Inform 6.

9/kind.§5 KOVA cache

Template interpreter commands

```
{-callv:compile_direction_object_constants}
```

Definitions

¶1. There is not very much to say about kinds, which are simply world objects with the `kind_flag` set.

The following kinds are special ones which NI needs to deal with directly: they are defined by the Standard Rules, and these pointers are set as NI notices them arriving. Unlike the special world objects, they cannot be left unset due to neglect, so need not be initialised to `NULL`.

```
world_object *kind_kind = NULL;
world_object *kind_room;
world_object *kind_thing;
world_object *kind_direction;
world_object *kind_door;
world_object *kind_container;
world_object *kind_supporter;
world_object *kind_backdrop;
world_object *kind_person;
world_object *kind_region;
world_object *latest_world_object_made_a_room = NULL;
```

---

§**1.** Every world object has one and only one kind: this routine sets it – which can happen more than once when asserting, since kinds are revised in the light of knowledge. Such revisions are allowed to specialise the kind (e.g., by changing a "person" to a "man") but not to contradict it (e.g., by changing a "supporter" to a "container").

```
int registered_directions = 0;
void set_kind(world_object *wo, world_object *k) {
    PROTECTED_MODEL_PROCEDURE;
    world_object *k2, *old_kind;
    if (wo == NULL) {
        LOG("Tried to set kind to $O\n", k);
        internal_error("Tried to set the kind of a null object");
    }
    if ((!(wo_of_kind(wo, kind_room))) &&
        ((k == kind_room) || (wo_of_kind(k, kind_room)))) {
        latest_world_object_made_a_room = wo;
    }
    if ((wo->kind_set_at != NULL) && (wo->kind != k) && (wo->kind != NULL)) {
```

```
        if (wo_of_kind(wo->kind, k)) return;
        if (wo_of_kind(k, wo->kind) == FALSE) {
            LOG("Tried to set kind of $O to $O\n", wo, k);
            quote_source(1, current_sentence);
            quote_source(2, wo->kind_set_at);
            quote_object(3, k);
            quote_object(4, wo->kind);
            handmade_problem(_P_(C9KindsIncompatible));
            issue_problem_segment(
                "You wrote %1, but that seems to contradict %2, as %3 and %4 "
                "are incompatible. (If %3 were a kind of %4 or vice versa "
                "there'd be no problem, but they aren't.)");
            issue_problem_end();
            return;
        }
    }
    if ((wo->kind != k) && (k == kind_direction)) {
        char i6_identifier_constant[32];
        int w1 = wo->word_ref1, w2 = wo->word_ref2;
        sprintf(i6_identifier_constant, "DirectionObject_%d", registered_directions);
        if (w1 < 0) {
            sentence_problem(_P_(C9NamelessDirection),
                "nameless directions are not allowed",
                "so writing something like 'There is a direction.' is forbidden.");
            return;
        }
        if (w2 > w1+2) {
            sentence_problem(_P_(C9DirectionTooLong),
                "directions may only have names of three or fewer words",
                "so writing something like 'North by north west is a direction.' is "
                "not allowed.");
            return;
        }
        if [[w1, w2 == up]] wo_up_direction = wo;
        if [[w1, w2 == down]] wo_down_direction = wo;
        wo->direction_index = registered_directions++;
        make_mapped_predicate(wo, i6_identifier_constant);
    }
    if (wo == k) {
        LOG("Tried to set kind of $O to itself\n", k);
        internal_error("Tried to set the kind of something to itself");
    }
    old_kind = wo->kind;
    wo->kind = k;
    for (k2 = k; k2 && (k2 != kind_kind) && (k2 != old_kind); k2=k2->kind)
        satisfies_generalisations_about(wo, k2);
    wo->kind_set_at = current_sentence;
    if (k == kind_room) {
        inference *i = create_inference(ISAROOM_INF, CERTAIN_CE);
        join_inference(i, inference_subject_wo(wo));
    }
    LOGIF(KIND_CHANGES, "Setting kind of $O to $O\n", wo, k);
}
```

```
void compile_direction_object_constants(OUTPUT_STREAM) {
    world_object *wo;
    int c = 0;
    WRITE("! Table of direction object alias constants:\n");
    LOOP_OVER(wo, world_object)
        if (wo_of_kind(wo, kind_direction))
            WRITE("Constant DirectionObject_%d = %s;\n", c++, wo->wo_I6_identifier);
}
```

The function set_kind is called from 6/asp.
The function compile_direction_object_constants is invoked by a command in a `.i6t` template file.

§**2.** Detecting whether a given world object is of a given kind involves recursion: if O is of kind "container", then it should pass the test for "thing" as well, since "container" is a kind of "thing". Note that only "kind" is allowed to be its own kind.

```
int wo_of_kind(world_object *wo, world_object *kd) {
    if ((wo == NULL) || (kd == NULL)) return FALSE;
    if (wo->kind == kd) return TRUE;
    if (wo == kind_kind) return FALSE;
    if (wo == wo->kind) {
        LOG("Offending self-kind object is $O\n", wo);
        internal_error("A world object has itself as its kind");
    }
    return wo_of_kind(wo->kind, kd);
}
```

The function wo_of_kind is called from 5/rel, 5/aph, 6/simp, 6/asp, 7/kov, 7/kix, 7/spec, 7/cosp, 8/assem, 8/knowc, 8/relv, 9/spabp, 9/pp, 9/model, 9/cot, 9/inpw, 9/map, 10/list and 11/ap.

§**3.** The number of objects of this kind.

```
int instance_count_for_kind(world_object *wo) {
    if (wo->kind_flag) {
        world_object *wo2;
        int c = 0;
        LOOP_OVER(wo2, world_object) {
            world_object *wo3 = wo2;
            if (wo2->kind_flag) continue;
            while (wo3 != kind_kind) {
                if (wo3->kind == wo) { c++; break; }
                wo3 = wo3->kind;
            }
        }
        return c;
    }
    return 0;
}
```

The function instance_count_for_kind is called from 10/tab and 14/i6t.

§**4.** Directions play a special role because sentences like "east of the treehouse is the garden" are parsed differently from sentences like "the nearby place property of the treehouse is the garden".

```
int is_a_direction_object(world_object *wo) {
    return wo_of_kind(wo, kind_direction);
}
```

The function is_a_direction_object is called from 8/sob, 8/mass and 8/relv.

§**5. KOVA cache.** This is managed by the "Kinds of Value" section, and explained there.

```
kind_of_value **wo_get_kova_cache_location(world_object *k) {
    if (k) return &(k->kovko_of_this);
    return NULL;
}
```

The function wo_get_kova_cache_location is called from 7/kov.

Spatial Relations 9/spabp

Purpose

To define the binary predicates corresponding to basic spatial relationships such as containment, support and being part of.

Definitions

¶1. The spatial relationships can be divided into three:

fundamental spatial relationships

```
binary_predicate *a_contains_b_predicate = NULL;
binary_predicate *a_supports_b_predicate = NULL;
binary_predicate *a_incorporates_b_predicate = NULL;
binary_predicate *a_carries_b_predicate = NULL;
binary_predicate *a_holds_b_predicate = NULL;
binary_predicate *a_wears_b_predicate = NULL;
binary_predicate *a_has_b_predicate = NULL;
```

indirect spatial relationships

```
binary_predicate *a_can_see_b_predicate = NULL;
binary_predicate *a_can_touch_b_predicate = NULL;
binary_predicate *a_conceals_b_predicate = NULL;
binary_predicate *a_encloses_b_predicate = NULL;
```

geographical spatial relationships

```
binary_predicate *a_adjacent_to_b_predicate = NULL;
binary_predicate *a_region_contains_b_predicate = NULL;
```

---

§**1. Initial stock.** These relations are all hard-wired in.

```
void SPATIAL_KBP_create_initial_stock(void) {
    ⟨Make built-in spatial relationships 2⟩;
    ⟨Make built-in indirect spatial relationships 3⟩;
    ⟨Make built-in geographical relationships 4⟩;
}
```

The function SPATIAL_KBP_create_initial_stock is called from 5/bp.

§**2.** Containment, support, incorporation, carrying, holding, wearing and possession. The "loop parent optimisation" is explained elsewhere, but the basic idea is that given a fixed y you can search for all x such that $B(x, y)$ by looking at the object-tree children of y at run-time. On a large work of IF, this cuts the number of cases to check by a factor of 100 or more. (But it can't be used for component parts, since those are not stored in the I6 object tree; nor for the holding relation, since that's a union of the others, and therefore includes incorporation.)

⟨Make built-in spatial relationships 2⟩ ≡

```
a_contains_b_predicate =
    make_pair_of_BPs(SPATIAL_KBP,
        bptd_early_new(-1, sch_new("ContainerOf(*1)")),
        bptd_blank(),
        "contains", "is-in", CONTAINSTHINGS_INF,
        NULL, sch_new("MoveObject(*2,*1)"), NULL,
        containment_V);
a_contains_b_predicate->loop_parent_optimisation_proviso = "ContainerOf";
a_contains_b_predicate->loop_parent_optimisation_ranger = "TestContainmentRange";
a_supports_b_predicate =
    make_pair_of_BPs(SPATIAL_KBP,
        bptd_early_new(kind_supporter_WR, sch_new("SupporterOf(*1)")),
        bptd_early_new(kind_thing_WR, NULL),
        "supports", "is-on", -1,
        NULL, sch_new("MoveObject(*2,*1)"), NULL,
        support_V);
a_supports_b_predicate->loop_parent_optimisation_proviso = "SupporterOf";
a_incorporates_b_predicate =
    make_pair_of_BPs(SPATIAL_KBP,
        bptd_early_new(kind_thing_WR, sch_new("(*1.component_parent)")),
        bptd_early_new(kind_thing_WR, NULL),
        "incorporates", "is-part-of", PARTOF_INF,
        NULL, sch_new("MakePart(*2,*1)"), NULL,
        incorporation_V);
a_carries_b_predicate =
    make_pair_of_BPs(SPATIAL_KBP,
        bptd_early_new(kind_person_WR, sch_new("CarrierOf(*1)")),
        bptd_early_new(kind_thing_WR, NULL),
        "carries", "is-carried-by", -1,
        NULL, sch_new("MoveObject(*2,*1)"), NULL,
        carrying_V);
a_carries_b_predicate->loop_parent_optimisation_proviso = "CarrierOf";
a_holds_b_predicate =
    make_pair_of_BPs(SPATIAL_KBP,
        bptd_early_new(kind_person_WR, sch_new("HolderOf(*1)")),
        bptd_early_new(kind_thing_WR, NULL),
        "holds", "is-held-by", -1,
        NULL, sch_new("MoveObject(*2,*1)"), NULL,
        holding_V);
can't be optimised, because parts are also held
a_wears_b_predicate =
    make_pair_of_BPs(SPATIAL_KBP,
        bptd_early_new(kind_person_WR, sch_new("WearerOf(*1)")),
        bptd_early_new(kind_thing_WR, NULL),
        "wears", "is-worn-by", -1,
        NULL, sch_new("WearObject(*2,*1)"), NULL,
```

```
        wearing_V);
    a_wears_b_predicate->loop_parent_optimisation_proviso = "WearerOf";
    a_has_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(-1, sch_new("OwnerOf(*1)")),
            bptd_blank(),
            "has", "is-had-by", -1,
            NULL, sch_new("MoveObject(*2,*1)"), NULL,
            possession_V);
    a_has_b_predicate->loop_parent_optimisation_proviso = "OwnerOf";
```

This code is used in §1.

§**3.** Visibility, touchability, concealment and enclosure: all relations which can be tested at run-time, but which can't be asserted or made true or false.

⟨Make built-in indirect spatial relationships 3⟩ ≡

```
    a_can_see_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(kind_thing_WR, NULL),
            bptd_early_new(kind_thing_WR, NULL),
            "can-see", "can-be-seen-by", -1,
            NULL, NULL, sch_new("TestVisibility(*1,*2)"),
            visibility_V);
    a_can_touch_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(kind_thing_WR, NULL),
            bptd_early_new(kind_thing_WR, NULL),
            "can-touch", "can-be-touched-by", -1,
            NULL, NULL, sch_new("TestTouchability(*1,*2)"),
            touchability_V);
    a_conceals_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(kind_thing_WR, NULL),
            bptd_early_new(kind_thing_WR, NULL),
            "conceals", "is-concealed-by", -1,
            NULL, NULL, sch_new("TestConcealment(*1,*2)"),
            concealment_V);
    a_encloses_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(kind_thing_WR, NULL),
            bptd_early_new(kind_thing_WR, NULL),
            "encloses", "is-enclosed-by", -1,
            NULL, NULL, sch_new("IndirectlyContains(*1,*2)"),
            enclosure_V);
```

This code is used in §1.

§4. Adjacency is a simple relation checked by looking at the current map. Regional containment is more subtle, because the meaning of "in" in the S-parser can be either containment or regional containment, depending on context.

⟨Make built-in geographical relationships 4⟩ ≡

```
    a_adjacent_to_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(kind_room_WR, NULL),
            bptd_early_new(kind_room_WR, NULL),
            "adjacent-to", "adjacent-from", -1,
            NULL, NULL, sch_new("TestAdjacency(*1,*2)"),
            adjacency_V);
    a_region_contains_b_predicate =
        make_pair_of_BPs(SPATIAL_KBP,
            bptd_early_new(kind_room_WR, NULL),
            bptd_early_new(kind_room_WR, NULL),
            "region-contains", "in-region", -1,
            NULL, NULL, sch_new("TestRegionalContainment(*2,*1)"),
            regional_containment_V);
```

This code is used in §1.

§5. **Second stock.** There is none – this is a family of relations which is all built in.

```
void SPATIAL_KBP_create_second_stock(void) {
}
```

The function SPATIAL_KBP_create_second_stock is called from 5/bp.

§6. Typechecking.

```
int SPATIAL_KBP_typecheck(binary_predicate *bp,
        kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    return DECLINE_TO_MATCH;
}
```

The function SPATIAL_KBP_typecheck is called from 5/bp.

§7. Assertion.

```
int SPATIAL_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    if ((wo0) && (wo1)) {
        place_ox_in_relation_to_oy(bp, wo0, wo1);
        return TRUE;
    }
    return FALSE;
}
```

The function SPATIAL_KBP_assert is called from 5/bp.

§**8.** The next routine is used when we are told that something is in a relationship with something else. From this we infer not merely the relationship, but also some contextual information implied by the fact that it is even possible for such a relationship to exist.

"In" requires delicate handling, because of the way that English uses it sometimes transitively and sometimes not. "The passport is in the desk", "The passport is in the Dining Room" and "The passport is in Venezuela" place the same object in a container, a room or a region respectively. Moreover, while we normally assume that nothing can be in more than one place at once, there is also the exception of "backdrop" objects: intended to represent widely spread, probably background, things, such as the sky. These generate `FOUNDIN_INF` rather than `PARENTAGE_INF` inferences to avoid piling up bogus inconsistencies.

```
void place_ox_in_relation_to_oy(binary_predicate *relation,
    world_object *wo0, world_object *wo1) {
    inference *i;
    int wo1_is_backdrop = FALSE, wo1_is_region = FALSE, wo0_is_region = FALSE;
    if ((wo1) && (wo_of_kind(wo1, kind_backdrop))) wo1_is_backdrop = TRUE;
    if ((wo1) && (wo_of_kind(wo1, kind_region))) wo1_is_region = TRUE;
    if ((wo0) && (wo_of_kind(wo0, kind_region))) wo0_is_region = TRUE;
    ⟨PIRS - Reject non-assertable relations 9⟩;
    ⟨PIR - Relations to regions 10⟩;
    ⟨PIR - Reject parts of rooms 11⟩;
    ⟨PIR - Deal with spatial relations 12⟩;
}
```

§**9.** This is the point at which non-assertable relations are thrown out.

⟨PIRS - Reject non-assertable relations 9⟩ ≡

```
    if ((relation != a_region_contains_b_predicate) &&
        (bp_can_be_made_true_at_runtime(relation) == FALSE)) {
        sentence_problem(_P_(C9Unassertable),
            "the relationship you describe is not exact enough",
            "so that I do not know how to make this assertion come true. "
            "For instance, saying 'The Study is adjacent to the Hallway.' "
            "is not good enough because I need to know in what direction: "
            "is it east of the Hallway, perhaps, or west?");
        return;
    }
```

This code is used in §8.

§**10.** Regions are a special enough case to be worth diverting now.

⟨PIR - Relations to regions 10⟩ ≡

```
    if (wo0_is_region) {
        if ((relation == a_incorporates_b_predicate) ||
            (relation == a_contains_b_predicate) ||
            (relation == a_region_contains_b_predicate)) {
            if (wo1_is_backdrop) {
                world_object *ref1;
                if (wo0) ref1 = wo0; else ref1 = latest_world_object;
                i = create_inference(FOUNDIN_INF, prevailing_mood);
                inf_set_object_references(i, ref1, wo0);
                join_inference(i, inference_subject_wo(wo1));
                return;
            }
            if (wo1_is_region == FALSE) {
                specification *spec = world_object_to_OBJECT_spec(wo0);
                assert_kind_of_object(wo1, kind_room);
                i = create_property_inference(inference_subject_wo(wo1), region_PRN, spec);
                inf_set_object_reference(i, wo0);
                join_inference(i, inference_subject_wo(wo1));
                wo1->in_region = wo0;
                return;
            }
            if ((wo1->in_region) && (wo1->in_region != wo0)) {
                LOG("Here OX is $O and is to be in both $O and $O\n", wo1,
                    wo1->in_region, wo0);
                sentence_problem(_P_(C9RegionInTwoRegions),
                    "each region can only be declared to be inside a single "
                    "other region",
                    "since although regions can be placed inside each other, "
                    "they are not permitted to overlap.");
                return;
            }
            wo1->in_region = wo0;
        } else {
            if (relation != a_region_contains_b_predicate) {
                sentence_problem(_P_(C9RegionRelation),
                    "regions can only contain rooms",
                    "and have no other relationships.");
                return;
            }
        }
    }
```

This code is used in §8.

§**11.** People sometimes try, a little hopefully, to subdivide rooms. Alas for them.

⟨PIR - Reject parts of rooms 11⟩ ≡
```
    if ((relation == a_incorporates_b_predicate) && (wo_of_kind(wo0, kind_room))) {
        sentence_problem(_P_(C9PartOfRoom),
            "this asks to make something a part of a room",
            "when only things are allowed to have parts.");
        return;
    }
```
This code is used in §8.

§**12.** Spatial relations are all essentially ways of saying that X is spatially within Y: perhaps it is inside a cavity of Y, or part of Y, carried by Y, worn by Y, and so on on. These relationships contain contextual information which go beyond what we can deduce for other relations. For instance,

On the desk is a liquorice twist.

generates the following three inferences:

O80⟨chocolatier's desk⟩ - SUPPORTSTHINGS_INF - Certain - 1:O86⟨liquorice twist⟩
O86⟨liquorice twist⟩ - PARENTAGE_INF - Certain - 1:O80⟨chocolatier's desk⟩
O86⟨liquorice twist⟩ - ISAROOM_INF - Impossible

⟨PIR - Deal with spatial relations 12⟩ ≡
```
{ world_object *ref1 = NULL, *ref2 = NULL;
    if (wo1 == wo0) {
        sentence_problem(_P_(C9MiseEnAbyme),
            "this asks to put something inside itself",
            "like saying 'the bottle is in the bottle'. ");
        return;
    }
    if ((relation == a_contains_b_predicate) ||
        (relation == a_supports_b_predicate)){
        if (wo1 != NULL) {
            i = create_inference(PARTOF_INF, IMPOSSIBLE_CE);
            inf_set_object_reference(i, wo0);
            join_inference(i, inference_subject_wo(wo1));
        }
    }
    if (relation == a_incorporates_b_predicate) {
        We now know that X is a component part
        if (wo1 != NULL) {
            i = create_inference(PARTOF_INF, CERTAIN_CE);
            inf_set_object_reference(i, wo0);
            join_inference(i, inference_subject_wo(wo1));
        }
    } else {
        if ((wo1_is_backdrop == FALSE) && (wo0_is_region == FALSE) && (wo0 != NULL)) {
            We now know that Y contains or supports things
            int kind_of_inference = bp_get_kind_of_inference(relation);
            if (kind_of_inference != -1) {
                i = create_inference(kind_of_inference, CERTAIN_CE);
                inf_set_object_reference(i, wo1);
                join_inference(i, inference_subject_wo(wo0));
            }
```

```
        }
    }
    We also know the parentage of X
    if (wo1_is_backdrop) {
        i = create_inference(FOUNDIN_INF, CERTAIN_CE);
        ref2 = wo0;
    } else {
        i = create_inference(PARENTAGE_INF, CERTAIN_CE);
    }
    if (wo0) ref1 = wo0; else ref1 = latest_world_object;
    inf_set_object_references(i, ref1, ref2);
    join_inference(i, inference_subject_wo(wo1));
    And that it cannot be a room
    i = create_inference(ISAROOM_INF, IMPOSSIBLE_CE);
    join_inference(i, inference_subject_wo(wo1));
    if (relation == a_wears_b_predicate) {
        i = create_inference(ISWORN_INF, CERTAIN_CE);
        join_inference(i, inference_subject_wo(wo1));
        if ((wearable_PRN = find_property_translating("wearable")) != NULL) {
            i = create_property_inference(inference_subject_wo(wo1), wearable_PRN, NULL);
            inf_set_certainty(i, LIKELY_CE);
            join_inference(i, inference_subject_wo(wo1));
        }
    }
}
```

This code is used in §8.

§13. **Compilation.** We need do nothing special: these relations can be compiled from their schemas.

```
int SPATIAL_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch) {
    return FALSE;
}
```

The function SPATIAL_KBP_compile is called from 5/bp.

§14. Problem message text.

```
int SPATIAL_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    return FALSE;
}
```

The function SPATIAL_KBP_describe_for_problems is called from 5/bp.

Map Connection Relations 9/mapbp

Purpose

To define one binary predicate for each map direction, such as "mapped north of".

Definitions

¶1. This section creates a family of implicit relations (implemented as binary predicates) corresponding to the different directions.

For every direction created, a predicate is created for the possibility of a map connection. For instance, "if Versailles is mapped north of the Metro" tests the "mapped-north" BP.

---

§**1. Initial stock.** There is none, since at the start of Inform's run no direction objects exist yet.

```
void MAP_CONNECTING_KBP_create_initial_stock(void) {
}
```

The function MAP_CONNECTING_KBP_create_initial_stock is called from 5/bp.

§**2. Subsequent creations.** Every direction created has a relation associated with it: for instance, "north" has the relation "X is mapped north of Y". Now a direction is a kind of object, but objects aren't created until after relations used to parse sentences are needed. In fact, however, directions are "noticed" at an earlier stage in Inform's run, so another two-step is needed:

```
binary_predicate *bp_create_sketchy_mapping_direction(int w1, int w2) {
    binary_predicate *bp;
    ⟨Create the mapping BP for the new direction 3⟩;
    return bp;
}
```

The function bp_create_sketchy_mapping_direction is called from 4/ofs.

§**3.** The names of these relations might look odd, for two reasons: (i) why is "mapped" optional in the case of above and below, but not the others? and (ii) why define "to be mapped east of" rather than "to be east of"? After all, that seems to be what is used in assertions like:

The Bakery is east of Pudding Lane.

In fact, the A-parser reads sentences like that by looking out specially for direction names plus "of" – so this is parsed without using the mapping predicate for "east". But it cannot read:

The Flour Cellar is below the Bakery.

as a direction name plus "of", since "below" is not the name of the direction "down", and anyway there is no "of". This is why `mapped_up_predicate` and `mapped_down_predicate` were special cases.

The answer to question (ii) is that the A-parser is better at avoiding ambiguities in assertions like

North of Patio Area is East of Gardens.

We don't want to define the relation "to be east of" to avoid clashing with the A-parser's method. We especially don't want to define "to be inside", because "inside" already has a meaning as containment ("the pearl in inside the jewellery box"). So we include the word "mapped" in the names of these relations, and while that is a little fussy, it avoids all such problems.

⟨Create the mapping BP for the new direction 3⟩ ≡

```
bp_term_details room_term = bptd_blank();
char dln[3*MAX_WORD_LENGTH+10];                 name of BP in debugging log, e.g., "north-map"
vocabulary_entry *rel_name;                     source text name of relation, e.g., "mapping-north"
vocabulary_entry *ve[5];                                          for name of prepositional usage
int i;
⟨Confect the various mapping relation names 4⟩;
bp = make_pair_of_BPs(MAP_CONNECTING_KBP,
    room_term, room_term, dln, NULL, -1, NULL, NULL, NULL, rel_name);
ve[0] = mapped_V;
for (i = 1; i <= w2-w1+1; i++) ve[i] = lw_array[w1+i-1].lw_identity;
if (![[w1, w2 == inside/outside]]) ve[i++] = of_V;
for (; i<5; i++) ve[i] = NULL;
register_pu(ve[0], ve[1], ve[2], ve[3], ve[4], FALSE, bp);
```

This code is used in §2.

§**4.** Some string hackery:

⟨Confect the various mapping relation names 4⟩ ≡

```
int wn = lexer_wordcount, i;
char relname[3*MAX_WORD_LENGTH+10];
print_text_to_string(w1, w2, dln); sprintf(dln + strlen(dln), "-map");
for (i=0; dln[i]; i++) if (dln[i] == ' ') dln[i] = '-';
sprintf(relname, "mapping-"); print_text_to_string(w1, w2, relname + strlen(relname));
for (i=0; relname[i]; i++) if (relname[i] == ' ') relname[i] = '-';
feed_into_lexer(relname, TRUE, FALSE);
rel_name = lw_array[wn].lw_identity;
```

This code is used in §3.

§**5.** And then, later, when the new direction comes into existence (i.e., not when the underlying object `wo` is created, but when its kind is first realised to be "direction"), the following routine is called to fill out the details of the BP. `i6_identifier` can be any string of text which evaluates in I6 to the object number of the direction object. It seems redundant here because surely if we know `wo`, we know its runtime representation; but that's not true – we need to call this routine at a time when the final identifier names for I6 objects have not yet been settled.

```
int mmp_call_counter = 0;
void make_mapped_predicate(world_object *wo, char *i6_identifier) {
    int w1 = wo->word_ref1, w2 = wo->word_ref2;
    if ((w1<0) || (w2 > w1+2)) internal_error("bad direction name");
    complete_mapped_predicate(wo, i6_identifier, relation_noticed(mmp_call_counter++));
}
void complete_mapped_predicate(world_object *wo, char *i6_identifier, binary_predicate *bp)
{
    if (bp == NULL) {
        sentence_problem(_P_(C9ImproperlyMadeDirection),
            "directions must be created by only the simplest possible sentences",
            "in the form 'North-north-west is a direction' only. Using adjectives, "
            "'called', 'which', and so on is not allowed. (In practice this is not "
            "too much of a restriction. I won't allow 'Clockwise is a privately-named "
            "direction.', but I will allow 'Clockwise is a direction. Clockwise "
            "is privately-named.')");
        return;
    }
    bp->term_details[0] = bptd_blank();                    bptd_new(kind_room, NULL);
    bp->term_details[1] = bptd_blank();                    bptd_new(kind_room, NULL);
    bp->test_function = sch_new_1("(MapConnection(*2,%s) == *1)", i6_identifier);
    bp->make_true_function = sch_new_1("AssertMapConnection(*2,%s,*1)", i6_identifier);
    bp->make_false_function = sch_new_1("AssertMapUnconnection(*2,%s,*1)", i6_identifier);
    bp->direction_object = wo;
}
```

The function make_mapped_predicate is called from 9/kind.

§**6. Second stock.** By this time, they all exist; there is nothing to add.

```
void MAP_CONNECTING_KBP_create_second_stock(void) {
}
```

The function MAP_CONNECTING_KBP_create_second_stock is called from 5/bp.

§7. Typechecking.

```
int MAP_CONNECTING_KBP_typecheck(binary_predicate *bp,
        kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    int t;
    for (t=0; t<2; t++)
        if ((can_we_cast_kovs(kovs_of_terms[t], kovko(kind_room)) == NEVER_MATCH) &&
            (can_we_cast_kovs(kovs_of_terms[t], kovko(kind_door)) == NEVER_MATCH)) {
        LOG("Term %d is $u but should be a room or door\n", t, kovs_of_terms[t]);
        issue_bp_typecheck_error(bp, kovs_of_terms[0], kovs_of_terms[1], tck);
        return NEVER_MATCH;
    }
    return ALWAYS_MATCH;
}
```

The function MAP_CONNECTING_KBP_typecheck is called from 5/bp.

§8. Assertion.

```
int MAP_CONNECTING_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    world_object *o_dir = bp_get_mapping_direction(bp);
    world_object *o_from = wo0;
    world_object *o_to = wo1;
    To have exits one must be a room
    inference *i = create_inference(ISAROOM_INF, prevailing_mood);
    join_inference(i, inference_subject_wo(o_from));
    i = create_inference(DIRECTION_INF, prevailing_mood);
    inf_set_object_references(i, o_to, o_dir);
    join_inference(i, inference_subject_wo(o_from));
    return TRUE;
}
```

The function MAP_CONNECTING_KBP_assert is called from 5/bp.

§9. Compilation. We need do nothing special: these relations can be compiled from their schemas.

```
int MAP_CONNECTING_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch) {
    return FALSE;
}
```

The function MAP_CONNECTING_KBP_compile is called from 5/bp.

§10. The correspondence with directions. (Speed really does not matter here.)

```
binary_predicate *bp_for_mapping_direction(world_object *dir) {
    binary_predicate *bp;
    LOOP_OVER(bp, binary_predicate)
        if (bp->direction_object == dir)
            return bp;
    return NULL;
}

world_object *bp_get_mapping_direction(binary_predicate *bp) {
    return bp->direction_object;
}
```

The function bp_for_mapping_direction is called from 8/relv.
The function bp_get_mapping_direction is called from 8/refpt.

§11. Problem message text.

```
int MAP_CONNECTING_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    return FALSE;
}
```

The function MAP_CONNECTING_KBP_describe_for_problems is called from 5/bp.

Explicit Relations 9/exrel

Purpose

To draw inferences from the relations created explicitly by the source text.

9/exrel.§1-11 Managing the BPs generated

---

§**1. Managing the BPs generated.** The relations created in this section belong to the EXPLICIT_KBP family, named so because their definitions are explicit in the source text. Initially, there are none.

```
void EXPLICIT_KBP_create_initial_stock(void) {
}
void EXPLICIT_KBP_create_second_stock(void) {
}
```

The function EXPLICIT_KBP_create_initial_stock is called from 5/bp.
The function EXPLICIT_KBP_create_second_stock is called from 5/bp.

§**2.** They typecheck by the default rule only:

```
int EXPLICIT_KBP_typecheck(binary_predicate *bp,
        kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    return DECLINE_TO_MATCH;
}
```

The function EXPLICIT_KBP_typecheck is called from 5/bp.

§**3.** They are asserted thus:

```
int EXPLICIT_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    if ((bp_term_kind_of_value(bp, 0)) || (bp_term_kind_of_value(bp, 1))) {
        inference *i = create_inference(VALUEARBITRARY_INF, prevailing_mood);
        inf_set_all_references(i, spec0, wo0, spec1, wo1);
        inf_set_bp(i, bp);
        join_inference(i, inference_subject_bp(bp));
        return TRUE;
    } else {
        if ((wo0) && (wo1)) {
            nons_place_ox_in_relation_to_oy(bp, wo1, wo0);
            return TRUE;
        }
    }
    return FALSE;
}
```

The function EXPLICIT_KBP_assert is called from 5/bp.

§**4.**

```
void nons_place_ox_in_relation_to_oy(binary_predicate *relation,
    world_object *ox, world_object *oy) {
    inference *i;
    ⟨PIR - Reject non-assertable relations 7⟩;
    ⟨PIR - Deal with equivalence relations 5⟩;
    ⟨PIR - Deal with other non-exclusive relations 6⟩;
    ⟨PIR - Deal with non-spatial relations 8⟩;
}
```

§**5.** Equivalence relations are handled entirely differently from other relations, because of their representation at run-time being so very different.

⟨PIR - Deal with equivalence relations 5⟩ ≡

```
    if ((bp_get_form_of_relation(relation) == Relation_Equiv) && (ox) && (oy)) {
        i = create_inference(MATCHING_INF, prevailing_mood);
        inf_set_property_name(i, bp_get_i6_storage_property(relation));
        inf_set_object_references(i, ox, ox);
        inf_set_bp(i, relation);
        join_inference(i, inference_subject_wo(oy));
        return;
    }
```

This code is used in §4.

§**6.** Now we get rid of other relationships where $B(x, y)$ and $B(x, z)$ are not necessarily contradictory where $y \neq z$. Note that if we have a symmetric various-to-various relation then we need to behave as if $B(y, x)$ had also been asserted whenever $B(x, y)$ has.

⟨PIR - Deal with other non-exclusive relations 6⟩ ≡

```
    if ((bp_allow_arbitrary_assertions(relation)) && (ox) && (oy)) {
        i = create_inference(ARBITRARY_INF, prevailing_mood);
        inf_set_object_references(i, ox, ox);
        inf_set_bp(i, relation);
        join_inference(i, inference_subject_wo(oy));
        if (bp_get_form_of_relation(relation) == Relation_Sym_VtoV) {
            i = create_inference(ARBITRARY_INF, prevailing_mood);
            inf_set_object_references(i, oy, oy);
            inf_set_bp(i, relation);
            join_inference(i, inference_subject_wo(ox));
        }
        return;
    }
```

This code is used in §4.

§**7.** This is the point at which non-assertable relations are thrown out.

⟨PIR - Reject non-assertable relations 7⟩ ≡
```
    if (bp_can_be_made_true_at_runtime(relation) == FALSE) {
        sentence_problem(_P_(C9Unassertable2),
            "the relationship you describe is not exact enough",
            "so that I do not know how to make this assertion come true. "
            "For instance, saying 'The Study is adjacent to the Hallway.' "
            "is not good enough because I need to know in what direction: "
            "is it east of the Hallway, perhaps, or west?");
        return;
    }
```

This code is used in §4.

§**8.** Those relations which involve arbitrary pairs of objects have already been dealt with, so we must now be left with one-to-one, one-to-various, various-to-one, or else spatial relations. We get rid of all but the tricky spatial relations now. Again, note the enforcement of symmetric behaviour: if $B(x, y)$ is asserted then we behave as if $B(y, x)$ had also been asserted.

⟨PIR - Deal with non-spatial relations 8⟩ ≡
```
    if (bp_is_explicit_with_runtime_storage(relation)) {
        infer_property_based_relation(relation, ox, oy);
        if ((bp_get_form_of_relation(relation) == Relation_Sym_OtoO) && (ox != oy))
            infer_property_based_relation(relation, oy, ox);
        return;
    }
```

This code is used in §4.

§**9.** We need do nothing special: these relations can be compiled from their schemas.

```
int EXPLICIT_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch) {
    return FALSE;
}
```

The function EXPLICIT_KBP_compile is called from 5/bp.

§**10.** Problem message text:

```
int EXPLICIT_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    return FALSE;
}
```

The function EXPLICIT_KBP_describe_for_problems is called from 5/bp.

§**11.** This routine converts the knowledge that $R(ox, oy)$ into a single inference. It can only be used for a simple subclass of the relations: those which store `oy`, the only thing related to `ox`, in a given property of `ox`. The beauty of this is that the "only thing related to" business is then enforced by the inference mechanism, since an attempt to assert both $R(x, y)$ and $R(x, z)$ will result in contradictory property value inferences for y and z.

```
void infer_property_based_relation(binary_predicate *relation,
    world_object *ox, world_object *oy) {
    if (bp_get_form_of_relation(relation) == Relation_VtoO) {
        world_object *swap=ox; ox=oy; oy=swap;
    }
    specification *spec = world_object_to_OBJECT_spec(oy);
    property_name *prn = bp_get_i6_storage_property(relation);
    inference *i = create_property_inference(inference_subject_wo(ox), prn, spec);
    join_inference(i, inference_subject_wo(ox));
}
```

Properties 9/prop

Purpose

World objects and kinds have "properties" associated with them. Some are either/or, while others hold values: a value-property always has a kind of value it must hold, and type-checking is used to ensure that it always does hold that kind of value. (Inform does not have a boolean type: so an either/or property is not a value property whose value is required to be of boolean type.) In this section of code, we consider "property names" – the properties, such as "open" or "carrying capacity", rather than knowledge about their values in the case of individual objects.

Template interpreter commands

```
17  {-callv:compile_attributes}
18  {-callv:compile_stub_properties}
18  {-routine:CreatePropertyOffsets}
```

Definitions

¶1. A property name is just that: a name given to a property, such as "carrying capacity" or "fixed in place". Property names do not correspond exactly to I6 properties in the compiled code, because some either/or properties have two names: "open" and "closed" refer to the same property, but with different implicit values for it.

Most properties belong to world objects (directions, rooms, things and so on), and are "physical", but some are "abstract" and belong to values. These are in effect the other columns in a table whose first column defines the possibilities for a new kind of value. (An implicit restriction here is that the same name cannot be both a physical and an abstract property.)

Sometimes the name of a property is the same as that of a kind of value. For instance, we might define a kind of value called "weight", and then say that a thing has a weight: that makes a property also called "weight", which is a value property whose value is always a weight.

Finally, some properties are "conditions", in the sense of "What condition is this in?": for instance the sentence

> The cask can be wedged open, bolted closed or stoved in.

sets up a new property as the condition of the cask, whose value must be one of these three named possibilities. (A new kind of value is set up whose three possible values these are.)

```
typedef struct property_name {
    int word_ref1, word_ref2;                          name of property
    struct property_permission *applicable_to;         lists who has permission to have this
    int used_by_i6_library_only;                       is this for private use of the I6 library?
    int shown_in_index;                                is this property shown in the indexes?
    int indexed_flag;                                  and has it been, thus far in index construction?
    int either_or;                                     is this an either/or property?
    int implemented_as_attribute;                      if so: is it an I6 attribute at run-time?
    int ephemeral;                                     and does it flicker on and off in a temporary way?
    struct property_name *negation;                    and which property name (if any) negates it?
```

```
    struct adjective_meaning *adjectival_meaning_registered;          and has it been made an
adjective yet?
    struct adjectival_phrase *adjectival_phrase_registered;                              similarly
    struct grammar_verb *eo_parsing_grammar;                          exotic forms used in parsing
    struct kind_of_value *property_value_kov;      if not either/or, what kind of value does it hold?
    struct binary_predicate *setting_bp;                                  and which relation sets it?
    int also_a_type;                            and is its name the same as that of the kind of value?
    int abstract_flag;                            and is it an abstract rather than physical property?
    int stores_1to1_relation;                          or is it used to implement a 1 to 1 relation?
    struct world_object *condition_of;                                 or is it a condition of an object?
    int condition_anonymously_named;                              if so, is it named just "... condition"?
    int translated;                           translated into an I6 library-defined property/attribute?
    char i6_name[32];                          the I6 name (whether defined by the I6 library or not)
    int table_offset;                    position in the property_metadata word array at run-time
    struct world_object *last_initialised_for;                    temporary use when compiling objects
    struct possession_marker pom;                      for temporary use when checking implications
    MEMORY_MANAGEMENT
} property_name;
```

The structure property_name is private to this section.

¶2. A few properties are treated specially by NI, and need to have their references stored in global variables. They are set as they are created, during the parsing of assertions in the Standard Rules.

```
property_name *wearable_PRN = NULL;                  needed as it interacts with the wearing relation
property_name *Inform_property_PRN = NULL;                  I6 dir_prop, for doors and directions
property_name *specification_PRN = NULL;                      a meta-property for indexing kinds
property_name *proper_named_PRN = NULL;                         an either/or property for names
property_name *plural_named_PRN = NULL;                         an either/or property for names
property_name *region_PRN = NULL;                          an I6 property giving the region of a room
property_name *other_side_PRN = NULL;                      an I6 property for the other side of a door
```

---

§**1.** Two special cases are "I6 direction property" and "I6 direction object", which are used by the Standard Rules as part of the link between I7 and the lower-level I6 library. We keep track of them mainly in order to exclude them from the index, as we don't want the user to see them or think about them.

A different sort of special case is the "specification" of a kind, which is text used in indexing, and not something inherited by its instances in the usual way.

```
property_name *create_property_name(int w1, int w2) {
    property_name *pn;
    specification *spec;
    kind_of_value *data_type;
    if [[w1, w2 == value]] {
        sentence_problem(_P_(BelievedImpossible),
            "the single word 'value' cannot be used as the name of a property",
            "because it has a much broader meaning already. Inform uses the "
            "word 'value' to mean any number, time of day, name of something, "
            "etcetera: and because of that very broadness, Inform cannot decide "
            "what kind of value a simple 'value' might be. So 'A door has "
```

```
        "a value' is not allowed; but 'A door has a number called the "
        "room number' would be fine.");
}

}
```

The function log_property_name is called from 2/dl and 9/model.
The function prn_is_used_by_i6_library_only is called from 4/edoc and 9/inpw.
The function prn_is_shown_in_index is called from 4/edoc.
The function prn_exclude_from_index is called from 5/rel.
The function prn_set_indexed_flag is called from 9/inpw.
The function prn_get_indexed_flag is called from 9/inpw.

§**2. Parsing property names.** In almost all cases (but see below) properties are parsed using the standard excerpt parser.

```
property_name *parse_property_name(int w1, int w2) {
    meaning_list *ml;
    ml = SP_excerpt(PROPERTY_MC, w1, w2);
    if (ml == NULL) return NULL;
    return RETRIEVE_POINTER_property_name(em_data(ml_meaning(ml)));
}
```

The function parse_property_name is called from 4/ofs, 6/treec, 7/data, 8/refpt, 9/pp, 9/madj, 9/vpbp, 12/cinv, 13/tfg and 14/i6t.

§**3.** The following asserts that `(w1,w2)` is certainly a property, which might or might not already exist, so must be created if it does not.

```
property_name *value_property_name_ref(int w1, int w2) {
    meaning_list *ml;
    ml = SP_excerpt(PROPERTY_MC, w1, w2);
    property_name *pn;
    if (ml == NULL) {
        pn = create_property_name(w1, w2);
        binary_predicate *bp = find_set_property_BP(w1, w2);
        if (bp == NULL) bp = make_set_property_BP(w1, w2);
        fix_property_bp(bp);
        fix_property_bp(bp_get_reversal(bp));
        pn->setting_bp = bp;
    } else pn = RETRIEVE_POINTER_property_name(em_data(ml_meaning(ml)));
    return pn;
}

property_name *property_name_ref(int w1, int w2) {
    meaning_list *ml;
    ml = SP_excerpt(PROPERTY_MC, w1, w2);
    property_name *pn;
    if (ml == NULL) {
        pn = create_property_name(w1, w2);
    } else pn = RETRIEVE_POINTER_property_name(em_data(ml_meaning(ml)));
    return pn;
}
```

The function value_property_name_ref is called from 4/ofs, 8/mass, 9/pp and 10/tab.

§**4.** Now the same: except that we require the property to have a given data type, if it already exists. We can widen the type if need be, but in the event that such a property already exists and has an incompatible type, we now have the possibility of failure – a problem message and a return value of a null pointer. So this routine does not guarantee success, like the last.

```
property_name *typed_property_name_ref(int w1, int w2, kind_of_value *kov) {
    property_name *prn = parse_property_name(w1, w2);
    if (kov == NULL) kov = kova(OBJECT_TY);
    if (prn) {
        switch(can_we_cast_kovs(kov, prn->property_value_kov)) {
            case ALWAYS_MATCH: break;
            case SOMETIMES_MATCH:
                if (can_we_cast_kovs(prn->property_value_kov, kov)
                    == ALWAYS_MATCH) {
                    prn->property_value_kov = kov;
                    break;
                }
            case NEVER_MATCH:
                sentence_problem(_P_(C9BadKOVForRelationProperty),
                    "that property already exists and contains a kind of value "
                    "incompatible with what we need here",
                    "so you will need to give it a different name.");
                return NULL;
        }
```

```
    } else {
        prn = create_property_name(w1, w2);
        prn->property_value_kov = kov;
    }
    return prn;
}
```

The function typed_property_name_ref is called from 5/rel.

§**5.** The following slow routine, not used very often, finds the length of the longest property name at the start of the excerpt `(w1,w2)`. This information is then used to cut text like "discovery score 13" into a name part ("discovery score") and a value part ("13").

```
int match_longest_pname(int w1, int w2) {
    int j, x1, x2, maxlen = -1;
    property_name *pn;
    LOOP_OVER(pn, property_name) {
        x1 = pn->word_ref1;
        x2 = pn->word_ref2;
        if (x2-x1 <= w2-w1) {
            for (j=0; j<=x2-x1; j++)
            for (j=0; j<=x2-x1; j++)
                if (compare_words(w1+j, x1+j) == FALSE) goto NotThisOne;
            if (maxlen < x2-x1) maxlen = x2-x1+1;
        }
        NotThisOne: ;
    }
    return maxlen;
}
```

The function match_longest_pname is called from 6/treec.

§**6. Properties of objects or values.** Some properties belong to objects, others to values. The default is objects, so we only need routines to change from this.

```
void prn_make_property_of_value(property_name *prn) {
    prn->abstract_flag = TRUE;
}
int prn_belongs_to_value(property_name *prn) {
    return prn->abstract_flag;
}
```

The function prn_make_property_of_value is called from 9/pp.
The function prn_belongs_to_value is called from 7/tc and 9/pp.

§**7. Permissions.** Each property has a list of permissions for its usage attached. These are important enough to have their own section: here, all we do is...

```
property_permission *prn_permission_list(property_name *prn) {
    return prn->applicable_to;
}
void prn_set_permission_list(property_name *prn, property_permission *pp) {
    prn->applicable_to = pp;
}
```

The function prn_permission_list is called from 9/qty, 9/pp and 13/gpr.
The function prn_set_permission_list is called from 9/pp.

§**8. Either/or properties.** A property name structure with the either/or flag set represents one which is true or false, but there is an additional oddity. "Open" and "closed", for instance, refer to two different property name structures, even though they are arguably better regarded as the names of the two possible mutually exclusive values of a single property. The `negation` field of such a property name refers to its antonym, so for "open" it points to "closed" and vice versa. (All the same, note that some either/or properties do not have explicit antonyms, so it should not be assumed that either/or property name structures always occur in pairs.)

The following routine, at any rate, makes an existing property name structure usable as either/or, registering its name as one which can be used adjectivally ("an open door"): it will of course already be registered as one which can be used as a noun in the context of properties.

```
property_name *prn_either_or_new(int w1, int w2, kind_of_value *kov) {
    property_name *prn;
    prn = property_name_ref(w1, w2);
    prn->either_or = TRUE;
    if ((kov == NULL) && (prn->adjectival_meaning_registered == NULL)) {
        adjective_meaning *am = am_new(EORP_KADJ, STORE_POINTER_property_name(prn),
            w1, w2);
        am_declare(am, w1, w2);
        am_set_domain_from_kov(am, kova(OBJECT_TY));

The function prn_either_or_new is called from 9/pp.
The function EORP_KADJ_parse is called from 5/aph.

§**9.** There are actually only two run-time implementations for either/or properties – as I6 attributes, and (because there are not many I6 attributes to play with) as I6 properties whose contents are always true or false – but it looks like four implementations because of the wrinkle that either/or properties tend to come in antonymical pairs, only one of which is actually stored at run-time. (Thus, "closed" is the absence of being "open".) Anyway, here are the four combinations.

```

The function prn_coincides_with_kind_of_value is called from 6/sconv and 8/refpt.

§**11. Relation-storing properties.** Some value properties are used for the run-time storage of 1-1 relations, as the following notes.

```
void prn_now_stores_1to1_relation(property_name *prn) {
    prn->stores_1to1_relation = TRUE;
}
int prn_stores_1to1_relation(property_name *prn) {
    return prn->stores_1to1_relation;
}
```

The function prn_now_stores_1to1_relation is called from 5/rel.
The function prn_stores_1to1_relation is called from 9/model.

§**12. Condition properties.** Nothing to do with conditions in the usual computing sense: these are value properties describing the current state, or "condition", of a world object which is simply modelled as having one of an enumerated range of possibilities. The name is always the object's name plus "condition": for instance, "lounge table condition".

```
property_name *prn_condition_new(world_object *wo, int n1, int n2) {
    property_name *prn;
    int w1, w2, anon;
    if (n1 >= 0) {
        w1 = n1; w2 = n2; anon = FALSE;
    } else {
        int ct = 0;
        LOOP_OVER(prn, property_name)
            if ((prn->condition_of == wo) && (prn->condition_anonymously_named))
                ct++;
        w1 = lexer_wordcount;
        splice_words(wo->word_ref1, wo->word_ref2);
        feed_into_lexer(" condition ", FALSE, FALSE);
        if (ct > 0) {
            char numb[32];
            sprintf(numb, " %d ", ct+1);
            feed_into_lexer(numb, FALSE, FALSE);
        }
        w2 = lexer_wordcount-1; anon = TRUE;
    }
    pcalc_prop *prop = prop_to_create_something(NULL, w1, w2);
    prop = prop_concatenate(prop, prop_to_make_a_kov());
    prop_true_in_world_model(prop);
    prn = value_property_name_ref(w1, w2);
    prn->either_or = FALSE;
    prn->condition_of = wo;
    prn->condition_anonymously_named = anon;
    return prn;
}
world_object *prn_condition_of_which_object(property_name *prn) {
    if (prn == NULL) return NULL;
    return prn->condition_of;                    which will be null if not a condition property
}
```

The function prn_condition_new is called from 9/pp.

The function prn_condition_of_which_object is called from 2/lexi, 7/stsp, 9/qty, 9/pp, 9/inf and 12/cinv.

§**13. I6 names of properties.** Some properties have I6 names mechanically generated by NI (indeed all properties initially have, as we saw above), but others must have names corresponding to those used in the I6 library: these are, we say, "translated". The following routine accomplishes that. It is brought to bear in response to explicit sentences in the standard rules file.

```
char *prn_get_i6_identifier(property_name *prn) {
    if (prn == NULL) internal_error("I6 identifier requested for null property");
    return prn->i6_name;
}
void set_translation(property_name *pn, char *t) {
    int i; char *to = pn->i6_name;
    for (i=0; ((t[i]) && (i<31)); i++) {
        if ((isalpha(t[i])) || (isdigit(t[i])) || (t[i] == '_')) to[i] = t[i];
        else to[i] = '_';
    }
    to[i] = 0;
    pn->translated = TRUE;
}
void compile_has_property(OUTPUT_STREAM, property_name *pn) {
    if (pn->implemented_as_attribute) {
        if (prn_either_or_stored_in_negation(pn))
            WRITE(" hasnt %s", pn->negation->i6_name);
        else
            WRITE(" has %s", pn->i6_name);
    } else {
        if (prn_either_or_stored_in_negation(pn))
            WRITE(".%s == false", pn->negation->i6_name);
        else
            WRITE(".%s == true", pn->i6_name);
    }
}
```

The function prn_get_i6_identifier is called from 5/rel, 6/equal, 6/defer, 6/cdefp, 9/rsdt, 7/vasp, 9/qty, 9/pp, 9/madj, 9/cmpbp, 9/vpbp, 9/model, 9/cot, 9/inpw, 12/cinv, 13/gtok, 13/gpr and 14/i6t.
The function compile_has_property is called from 9/inpw and 13/gpr.

§**14.** Conversely, the following function finds which NI property name represents, say, "plural-name", or some other I6 library attribute or property. (In fact at present it is used only to find "initial", "scenery", "description" and "wearable", and runs only about 200 times on a large game, so its inefficiency is unimportant.)

```
property_name *find_property_translating(char *t) {
    property_name *pn;
    LOOP_OVER(pn, property_name)
        if ((pn->translated) && (strcmp(pn->i6_name, t) == 0))
            return pn;
    return NULL;
}
```

The function find_property_translating is called from 9/spabp and 9/model.

§**15.** And this is the routine which is called by the assertion maker to set property name translations.

```
void property_translates(parse_node *pn) {
    parse_node *p1 = pn->down->next;
    parse_node *p2 = pn->down->next->next;
    char *p = lw_array[p2->word_ref1].lw_text;
    property_name *pname = parse_property_name(p1->word_ref1, p1->word_ref2);
    if (pname == NULL)  {
        sentence_problem(_P_(C9NonPropertyTranslated),
            "this property does not exist",
            "so cannot be translated.");
        return;
    }
    if (pname -> translated) {
        sentence_problem(_P_(C9TranslatedTwice),
            "this property has already been translated",
            "so there must be some duplication somewhere.");
        return;
    }
    if (pname->either_or) {
        pname->implemented_as_attribute = TRUE;
        if (pname->negation)
            pname->negation->implemented_as_attribute = TRUE;
    }
    if ((strcmp(p, "workflag") == 0) ||
        (strcmp(p, "concealed") == 0) ||
        (strcmp(p, "mentioned") == 0)) {
        pname->ephemeral = TRUE;
        if (pname->negation)
            pname->negation->ephemeral = TRUE;
    }
    LOGIF(PROPERTY_TRANSLATIONS, "Property <$Y", pname);
    set_translation(pname, p);
    LOGIF(PROPERTY_TRANSLATIONS, "> translates as <$Y>\n", pname);
}
```

The function property_translates is called from 2/isn.

§**16. Compilation.** This subsection begins with code made necessary by oddities in the syntax of Inform 6. I6 distinguishes either/or properties as "attributes", which must be declared before use, but are then present for every object; and others as "properties", which need not be declared before use, but are only present as specified.

The following routine is, perhaps surprisingly, used only when declaring objects: not when compiling regular code.

```
void write_attribute_name(OUTPUT_STREAM, property_name *pn, int truth_state) {
    if (pn->implemented_as_attribute) {
        WRITE("  has ");
        if (pn->translated) {
            if (truth_state == FALSE) WRITE("~");
            WRITE("%s", pn->i6_name);
            return;
        }
        if (prn_either_or_stored_in_negation(pn)) {
            if (truth_state == TRUE) WRITE("~");
            WRITE("%s", pn->negation->i6_name);
            return;
        }
        if (truth_state == FALSE) WRITE("~");
        WRITE("%s", pn->i6_name);
    } else {
        WRITE("  with ");
        if (pn->translated) {
            WRITE("%s", pn->i6_name);
            if (truth_state == FALSE) WRITE(" false");
            else WRITE(" true");
            return;
        }
        if (prn_either_or_stored_in_negation(pn)) {
            WRITE("%s", pn->negation->i6_name);
            if (truth_state == FALSE) WRITE(" true");
            else WRITE(" false");
            return;
        }
        WRITE("%s", pn->i6_name);
        if (truth_state == FALSE) WRITE(" false");
        else WRITE(" true");
    }
}
```

The function write_attribute_name is called from 9/cot.

§**17.** We make one exception to the rule about not declaring properties explicitly: those explicitly declared are handled slightly more efficiently at run-time, and can also be made "additive", meaning that they inherit values from classes in a way which concatenates lists. This is what we want for the special property which records the kind of an object (which we need in order to check, at run-time, that various property manipulations are safe and legal).

```
int no_attributes_made = 0, i7_fbna_made = FALSE;
void compile_attributes(OUTPUT_STREAM) {
    property_name *prn;
    LOOP_OVER(prn, property_name) {
        if ((prn->either_or) && (prn->implemented_as_attribute)) {
            if (prn_either_or_stored_in_negation(prn)) continue;
            if (prn->translated == FALSE) {
                if (++no_attributes_made >= 13) {
                    prn->implemented_as_attribute = FALSE;
                    if (prn->negation)
                        prn->negation->implemented_as_attribute = FALSE;
                } else {
                    WRITE("Attribute %s;\n", prn->i6_name);
                }
                if (no_attributes_made == 13) {
                    i7_fbna_made = TRUE;
                    WRITE("Constant FBNA_PROP_NUMBER = %s;\n", prn->i6_name);
                }
                prn->translated = TRUE;
            }
        }
    }
}
```

The function compile_attributes is invoked by a command in a `.i6t` template file.

§**18.** Various things mis-compile in I6 if it should happen that a property, by not being used anywhere, never gets created as a symbol. So we compile stub definitions to give meanings (it doesn't matter what) to property names which would otherwise go unrecognised.

The FBNA is the First Boolean Not to be an Attribute, and relates to the dodge we use to store further attributes in I6 when the Z-machine's stock has run out.

```
void compile_stub_properties(OUTPUT_STREAM) {
    property_name *prn;
    binary_predicate *bp;
    LOOP_OVER(prn, property_name) {
        if ((prn->either_or == TRUE)
            && (prn->negation != NULL)
            && (prn->negation->translated)) continue;
        WRITE("#ifndef %s; Constant %s = 0; #endif;\n",
            prn->i6_name, prn->i6_name);
    }
    LOOP_OVER(bp, binary_predicate)
        if (bp_allow_arbitrary_assertions(bp)) {
            WRITE("#ifndef relation_index_L%d; Constant relation_index_L%d = 0; #endif;",
                bp->allocation_id, bp->allocation_id);
            WRITE("#ifndef relation_index_R%d; Constant relation_index_R%d = 0; #endif;",
```

```
                bp->allocation_id, bp->allocation_id);
        }
    if (i7_fbna_made == FALSE) WRITE("Constant FBNA_PROP_NUMBER = 10000;\n");
}

void prn_offset_in_runtime_metadata_table_is(property_name *prn, int pos) {
    prn->table_offset = pos;
}

void compile_CreatePropertyOffsets_routine(OUTPUT_STREAM) {
    property_name *prn;
    WRITE("[ CreatePropertyOffsets i;\n"); INDENT;
    WRITE("for (i=0: i<%d: i++) attribute_offsets-->i = -1;\n",
        50 + NUMBER_CREATED(property_name));
    WRITE("for (i=0: i<%d: i++) property_offsets-->i = -1;\n",
        100 + NUMBER_CREATED(property_name));
    LOOP_OVER(prn, property_name) {
        if (prn->either_or == FALSE) continue;
        if (prn->negation != NULL) {
            if (prn->negation->translated) continue;
        }
        if (prn->implemented_as_attribute)
            WRITE("attribute_offsets-->%s = %d;\n", prn->i6_name,
                prn->table_offset);
        else
            WRITE("attribute_offsets-->(50 + %s - FBNA_PROP_NUMBER) = %d;\n",
                prn->i6_name, prn->table_offset);
    }
    LOOP_OVER(prn, property_name) {
        if (prn->either_or == TRUE) continue;
        WRITE("property_offsets-->%s = %d;\n", prn->i6_name,
            prn->table_offset);
    }
    OUTDENT; WRITE("];\n");
}

possession_marker *prn_get_possession_marker(property_name *prn) {

The function prn_get_last_initialised_for is called from 9/pp.

Property Permissions 9/pp

Purpose

To enforce the domain of properties: for instance, that a door can be open or closed but that an animal cannot, or that a person can have a carrying capacity but that a door cannot.

9/pp.§2-3 Visible properties; §4 Compiling unspecified but permitted properties; §5-6 Considering visible properties; §7-8 Actual provision; §9 Declaring properties; §10-12 "Can be" assertions declaring properties; §13 Numberspace forcer; §14 Property metadata

---

Template interpreter commands

```
13    {-callv:compile_property_numberspace_forcer}
14    {-array:property_metadata}
```

Definitions

¶1. Each property name has a linked list of objects and kinds which are allowed to provide it. There is a tacit form of multiple-inheritance going on here, even though NI is officially a single-inheritance language from an objects-and-classes point of view: the property "open", for instance, exists for both doors and containers, even though neither is a kind of the other.

```
typedef struct property_permission {
    struct property_name *property_granted;                    which property is permitted
    struct parse_node *where_granted;                          sentence granting the permission
    struct world_object *wo_with_permission;                   either a world object has permission...
    int visible_to_parser;                                     if so, does the run-time I6 parser recognise it?
    int visibility_condition_w1, visibility_condition_w2;      (at least if...?)
    struct kind_of_value *kov_with_permission;                 ...or a kind of value has permission
    int storage_table_id, storage_column_id;                   the table and column reference
    struct property_permission *next;                          in list of permissions
    MEMORY_MANAGEMENT
} property_permission;
```

The structure property_permission is private to this section.

¶2.

```
property_permission *latest_property_permission = NULL;
```

---

§**1.** The following routine declares that permission is granted: as can be seen, each world object keeps a linked list of its own permissions.

```
property_permission *new_property_permission(void) {
    property_permission *pp = CREATE(property_permission);
    pp->wo_with_permission = NULL;
    pp->kov_with_permission = NULL;
    pp->property_granted = NULL;
    pp->next = NULL;
    pp->visible_to_parser = FALSE;
    pp->visibility_condition_w1 = -1;
    pp->visibility_condition_w2 = -1;
    pp->where_granted = current_sentence;
    pp->storage_table_id = -1;
    pp->storage_column_id = -1;
    latest_property_permission = pp;
    return pp;
}
void kind_provides_property(world_object *k, property_name *pn) {
    PROTECTED_MODEL_PROCEDURE;
    property_permission *pp, *pp2;
    LOGIF(PROVISION, "Allowing $O to provide $Y\n", k, pn);
    if (k == NULL) internal_error("Tried to give permission to null object");
    if (k == kind_kind)
        sentence_problem(_P_(C9PropertyOfKind),
            "this seems to give a property to all kinds",
            "rather than to objects or values, which are the only things "
            "capable of having properties. For instance, 'A vehicle has a "
            "number called maximum speed' is fine, but not 'A kind has a "
            "number called coolness rating'.");
    pp = new_property_permission();
    pp->wo_with_permission = k;
    pp->property_granted = pn;
    pp2 = prn_permission_list(pn);
    if (pp2 == NULL) {
        prn_set_permission_list(pn, pp);
    } else {
        while (pp2->next != NULL) {
            if (pp2->wo_with_permission == k) { DESTROY(pp, property_permission); return; }
            pp2 = pp2->next;
        }
        if (pp2->wo_with_permission == k) { DESTROY(pp, property_permission); return; }
        pp2->next = pp;
    }
    update_adjectival_forms(pn);
}
```

The function kind_provides_property is called from 9/provr.

§**2. Visible properties.** A visible property is one which can be used to describe an object: for instance, if colour is a visible property of a car, then it can be called "green car" if and only if the current value of the colour of the car is "green".

Properly speaking it is not the property which is visible, but the combination of property and object (or kind): thus the following test depends on a property permission and not a mere property.

```
int pp_visible_to_wo(property_permission *pp, world_object *wo,
    int allow_inheritance) {
    if ((pp->wo_with_permission) && (pp->visible_to_parser > 0)) {
        if (pp->wo_with_permission == wo) return TRUE;
        if ((allow_inheritance) &&
            (pp->wo_with_permission->kind_flag) && (wo_of_kind(wo, pp->wo_with_permission)))
            return TRUE;
    }
    return FALSE;
}
```

The function pp_visible_to_wo is called from 13/gpr.

§**3.** Rolling this up to see if anything is visible:

```
int pr_any_visible_to_wo(world_object *wo, int allow_inheritance) {
    property_name *pr;
    LOOP_OVER(pr, property_name) {
        property_permission *pp;
        for (pp = prn_permission_list(pr); pp; pp = pp->next)
            if (pp_visible_to_wo(pp, wo, allow_inheritance))
                return TRUE;
    }
    return FALSE;
}
```

The function pr_any_visible_to_wo is called from 13/gpr.

§**4. Compiling unspecified but permitted properties.** If the source specified that, say, "A container has a number called sufficiency", then we need to compile the property even when no explicit value was given for it (so that it does not occur in the inferences for the object `wo`). Its initial value will be the default initial value for its type.

This stricture does not apply to boolean properties, as they are stored as I6 attributes and always exist: and they already have the default value of being false, which is what we want. So we need do nothing.

```
void compile_permitted_but_unspecified_properties(OUTPUT_STREAM, world_object *wo) {
    property_permission *pp;
    LOOP_OVER(pp, property_permission) {
        property_name *prn = pp->property_granted;
        if ((pp->wo_with_permission == wo) &&
            (prn_is_value_property_made_by_ni(prn)) &&
            (prn_get_last_initialised_for(prn) != wo)) {
            WRITE(" with %s ", prn_get_i6_identifier(prn));
            compile_pval_default(OUT, prn);
            WRITE(",\n");
        }
        if ((pp->wo_with_permission == wo) && (prn_is_either_or(prn)) &&
```

```
            (prn_either_or_implemented_as_attribute(prn) == FALSE) &&
            (prn_get_last_initialised_for(prn) != wo)) {
            WRITE(" with %s false,\n", prn_get_i6_identifier(prn));
        }
    }
}
void compile_pval_default(OUTPUT_STREAM, property_name *prn) {
    kind_of_value *kov = prn_get_kind_of_value(prn);
    LOGIF(OBJECT_COMPILATION, "Initialising: $Y\n", prn);
    if (compile_default_value(OUT,
        kov, prn->word_ref1, prn->word_ref2, "property") == FALSE) {
        quote_words(1, prn->word_ref1, prn->word_ref2);
        handmade_problem(_P_(C9PropertyUninitialisable));
        if (prn_get_kind_of_value(prn) == NULL)
            issue_problem_segment(                                    believed not to happen
            "I am unable to put any value into the property '%1', because "
            "it was created so vaguely that I cannot tell what kind of "
            "value it should hold. (A number, a time, some text perhaps?)");
        else issue_problem_segment(
            "I am unable to put any value into the property '%1', because "
            "it seems to have a kind of value which has no actual values.");
        issue_problem_end();
    }
}
```

The function compile_permitted_but_unspecified_properties is called from 9/cot.
The function compile_pval_default is called from 9/prop.

§5. Considering visible properties.

```
int pp_visibility_level(property_permission *pp) {
    return pp->visible_to_parser;
}
specification *pp_get_visibility_condition(property_permission *pp) {
    specification *spec;
    if (pp->visibility_condition_w1 == -1) return NULL;
    spec = parse_expression(pp->visibility_condition_w1, pp->visibility_condition_w2, CONDITION_EXPCON);
    if (validate_when(spec) == FALSE) {
        LOG("$X", spec);
        current_sentence = pp->where_granted;
        sentence_problem(_P_(C9BadVisibilityWhen),
            "the condition after 'when' makes no sense to me",
            "although otherwise this worked - it is only the part after 'when' "
            "which I can't follow.");
        pp->visibility_condition_w1 = -1;
        pp->visibility_condition_w2 = -1;
        return NULL;
    }
    return spec;
}
```

The function pp_visibility_level is called from 13/gpr.
The function pp_get_visibility_condition is called from 13/gpr.

§**6.** Kinds of value can also provide properties, when they have been defined by table.

```
void kov_provides_property(kind_of_value *kov, property_name *pn) {
    PROTECTED_MODEL_PROCEDURE;
    property_permission *pp, *pp2;
    LOGIF(PROVISION, "Allowing $u to provide $Y\n", kov, pn);
    if (kov == NULL) internal_error("Tried to give permission to null type");
    pp = new_property_permission();
    pp->kov_with_permission = kov;
    prn_make_property_of_value(pn);
    pp->property_granted = pn;
    pp2 = prn_permission_list(pn);
    if (pp2 == NULL) {
        prn_set_permission_list(pn, pp);
    } else {
        while (pp2->next != NULL) {
            if (kov_compare(pp2->kov_with_permission, kov)) {
                DESTROY(pp, property_permission);
                return;
            }
            pp2 = pp2->next;
        }
        if (kov_compare(pp2->kov_with_permission, kov)) {
            DESTROY(pp, property_permission);
            return;
        }
        pp2->next = pp;
    }
    update_adjectival_forms(pn);
}

void pp_set_table_storage(property_permission *pp, int t, int i) {
    pp->storage_table_id = t;
    pp->storage_column_id = i;
}

void pp_register_as_adjectival(quantity *q, property_name *prn) {
    property_permission *pp;
    int make_object_form = FALSE;
    for (pp = prn_permission_list(prn); pp; pp = pp->next) {
        if (pp->kov_with_permission)
            register_as_adjectival_quantity_domain(q, prn,
                pp->kov_with_permission, NULL);
        else make_object_form = TRUE;
    }
    if (make_object_form)
        register_as_adjectival_quantity_domain(q, prn,
            NULL, prn_condition_of_which_object(prn));
}

int pp_get_prn_offset_in_kov(property_name *pn, kind_of_value *kov) {
    int ct = 0;
    property_name *try_prn;
    LOOP_OVER(try_prn, property_name) {
        if ((prn_is_either_or(try_prn)) && (prn_either_or_get_negation(try_prn))) {

The function does_kov_provide is called from 9/provr.
The function compile_value_properties is called from 9/cot.
The function seek_permission is called from 13/tfg.
The function pp_index_applicabilities is called from 9/qty and 9/prop.

§**7. Actual provision.** It is one thing to have permission to have a given property: quite another actually to have it. So the following code looks to see, and is somewhat analogous to I6's "provides" operator. We can only find out by looking through the inferences stored for the object. We need to go to a little trouble with boolean properties: if a "closed" inference can be found, then "open" is provided as well, even though there is no explicit reference to it.

```
inference *provision_inference; int provision_sign = 1;
int does_kind_provide_dash(world_object *k, property_name *prn) {
    inference *inf;
    property_permission *pp;
    while ((k != NULL) && (k != kind_kind)) {
        KNOWLEDGE_LOOP(inf, k, PROPERTY_INF) {
            if ((inf_get_property_name(inf) == prn)
                && (provision_inference == NULL)) {
                provision_sign = 1;
                provision_inference = inf;
            }
            if ((prn_is_either_or(prn))
                && (prn_either_or_get_negation(prn))
                && (inf_get_property_name(inf) == prn_either_or_get_negation(prn))
                && (provision_inference == NULL)) {
                provision_sign = -1;
                provision_inference = inf;
            }
        }
        pp = prn_permission_list(prn);
        while (pp != NULL) {
            if (pp->wo_with_permission == k) return TRUE;
            pp = pp->next;
        }
        k = k->kind;
    }
    return FALSE;
}
int does_kind_provide(world_object *k, property_name *prn) {
    int f;
    provision_sign = 1;
    provision_inference = NULL;
    f = does_kind_provide_dash(k, prn);
    if ((f) || (prn_is_value_property(prn)) ||
        (prn_either_or_get_negation(prn) == NULL)) return f;
    return does_kind_provide_dash(k, prn_either_or_get_negation(prn));
}
```

The function does_kind_provide is called from 9/model and 9/inpw.

§**8.** Provision is handled identically for objects and kinds, but it was not always so, and might one day not be so again. We therefore keep two different routines, even though they do the same thing right now.

```
int does_object_provide(world_object *k, property_name *prn) {
    return does_kind_provide(k, prn);
}
```

The function does_object_provide is called from 7/tc, 8/imp and 9/model.

§**9. Declaring properties.** The following handles sentences like

A container has a number called rating.

in which `kind_ref` would be "a container" and `pname` would be "a rating".

```
property_name *recursively_declare_properties(parse_node *kind_ref,

```

The function recursively_declare_properties is called from 8/mass.

§**10. "Can be" assertions declaring properties.** The following handles sentences like

A container can be voluminous, middling or poky.

The next routine breaks up the list of choices, returning the number of possibilities noticed (so in this example, 3).

```
int or_list(parse_node *p) {
    int w1 = p->word_ref1;
    int w2 = p->word_ref2;
    int i = w1, count = 0;
    if (pn_get_node_type(p) == AND_NT) {
        return or_list(p->down) + or_list(p->down->next);
    }
    while (i<w2) {
        i++;
        if [[word i == COMMA/or]] {
            graft(new_nounphrase_raw(w1, i-1), p);
            pn_set_node_type(p, AND_NT);
            w1 = i+1; count++;
        }
    }
    if (w1 <= w2) { graft(new_nounphrase_raw(w1, w2), p); count++; }
    return count;
}
```

§**11.** Here we declare a subtree of such options as constants of some given type. We return the first-mentioned option as a quantity.

```
quantity *declare_kov_values(parse_node *p, kind_of_value *kov, int top,
    quantity *earliest) {
    if (p == NULL) return earliest;
    if [[p == either ...]] {
        sentence_problem(_P_(C9EitherOnThree),
            "that looks like an attempt to use 'either' on a list of "
            "three or more possibilities",
            "which is not allowed. (Technically it ought to be legal "
            "to have a property whose name actually starts with 'either' "
            "but the confusion would be just too awful to contemplate.)");
        if (p->word_ref1 < p->word_ref2) p->word_ref1++;
    }
    int w1, w2, cw1, cw2, i;

            LOG("Already means: $S\n", spec);
            quote_source(1, current_sentence);
            quote_words(2, pw1, pw2);
            quote_spec(3, spec);
            handmade_problem(_P_(C9PropertyAlreadyKnown));
            issue_problem_segment(
                "In %1, one of the values you supply as a possibility is '%2', "
                "but this already has a meaning (as %3).");
            issue_problem_end();
        }
        pcalc_prop *prop = prop_to_create_something(kov, pw1, pw2);
        prop_true_in_world_model(prop);
        q = latest_quantity;
        if (earliest == NULL) earliest = q;
    }
    if ((top) || (pn_get_node_type(p) == AND_NT))
        earliest =
            declare_kov_values(p->down, kov, FALSE, earliest);
    if (top == FALSE)
        earliest =
            declare_kov_values(p->next, kov, FALSE, earliest);
    return earliest;
}
```

§**12.** Lastly, the actual routine to handle the assertion. If there are only one or two alternatives, then we implement the property as a boolean, and the default is for it not to hold; but if there are three or more, then we create a new type associated with the given object (or kind), called "N condition", where "N" is the name of the object in question. In this case, the default value is the *first* mentioned. The beta-testers felt that this was an anomaly in the language, and I suspect they're right, but it isn't obvious to me what a better system would be.

```

§**13. Numberspace forcer.** This is to do with I6 creating properties in a different order from I7, so that the I6 property numbering sequence does not match the I7 creation sequence: as a result no run-time test by I6 could safely determine whether or not I7 had chosen to implement an either/or property as an I6 attribute or an I6 property. We might for example define lots of new either/or properties first for thing, thus kicking I7 to the point where it is forced to use I6 attributes; then sneak back and define an either/or property for a room. As NI defines the room class before the thing class, the new room property gets a lower I6 property number than the thing properties, which means numerical comparisons with the magic threshold property number `FBNA_PROP_NUMBER` would fail.

We get around this by creating the following spurious object before the class hierarchy and object tree are created: its properties are therefore all new creations, and since we declare them in I7 creation order, they are now allocated I6 property numbers in a sequence matching this.

```
void compile_property_numberspace_forcer(OUTPUT_STREAM) {
    property_name *prn;
    WRITE("Object property_numberspace_forcer\n");
    LOOP_OVER(prn, property_name)
        if ((prn_is_either_or(prn)) &&
            (prn_either_or_implemented_as_attribute(prn) == FALSE) &&
            (prn_either_or_stored_in_negation(prn) == FALSE))
                WRITE("  with %s false\n", prn_get_i6_identifier(prn));
    WRITE(";\n");
}
```

The function compile_property_numberspace_forcer is invoked by a command in a `.i6t` template file.

§14. Property metadata. The run-time system needs to know quite a lot of what NI knows about properties: in particular, what is allowed to belong to what.

The I6 routine `CreatePropertyOffsets` looks a little odd at first sight. The table contains no data which is in any sense variable, so why not simply initialise it explicitly here in NI? Why have to run a routine at run-time to do the job? The answer is that in NI we know the names we are giving the properties in the I6 source – "open", for instance – but not what property numbers I6 will compile these to. (And we cannot predict in what order I6 will create them: it would be hazardous to guess, anyway, because I6 or its library may well change.)

```
void compile_property_metadata_array(OUTPUT_STREAM) {
    int pos; property_name *prn;
    WRITE("Array property_metadata --> \n    ");
    pos = 0;
    LOOP_OVER(prn, property_name) {
        property_permission *pp;
        if ((prn_is_either_or(prn))
            && (prn_either_or_stored_in_negation(prn))) continue;
        prn_offset_in_runtime_metadata_table_is(prn, pos);
        pp = prn_permission_list(prn);
        WRITE("\"");
        print_text_to_file(prn->word_ref1, prn->word_ref2, OUT);
        WRITE("\" ");
        pos++;
        while (pp != NULL) {
            if (pp->wo_with_permission == NULL) WRITE("0 ");
            else
                if (wo_get_I6_representation(pp->wo_with_permission))
                    WRITE("%s ", wo_get_I6_representation(pp->wo_with_permission));
            pos++;
            pp = pp->next;
        }
        if (strcmp(prn_get_i6_identifier(prn), "light") == 0) {
            WRITE("%s %s ",
                wo_get_I6_representation(kind_room),
                wo_get_I6_representation(kind_thing));
            pos+=2;
        }
        WRITE("NULL\n    "); pos++;
    }
    WRITE(";\n");
}
```

The function compile_property_metadata_array is invoked by a command in a `.i6t` template file.

The Provision Relation 9/provr

Purpose

To define the provision relation, which determines which properties can be held by which objects.

Definitions

¶1.

```
binary_predicate *a_provides_b_predicate = NULL;
```

---

§**1. Initial stock.** This relation is hard-wired in.

```
void PROVISION_KBP_create_initial_stock(void) {
    a_provides_b_predicate =
        make_pair_of_BPs(PROVISION_KBP,
            bptd_blank(), bptd_blank(),
            "provides", NULL, -1, NULL, NULL, NULL,
            provision_V);
}
```

The function PROVISION_KBP_create_initial_stock is called from 5/bp.

§**2. Second stock.** There is none, of course.

```
void PROVISION_KBP_create_second_stock(void) {
}
```

The function PROVISION_KBP_create_second_stock is called from 5/bp.

§**3. Typechecking.**

```
int PROVISION_KBP_typecheck(binary_predicate *bp,
        kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    if (is_kova(kovs_of_terms[1], PROPERTY_TY)) return ALWAYS_MATCH;
    if (is_kova(kovs_of_terms[1], OBJECT_TY)) return ALWAYS_MATCH;
    quote_kov(4, kovs_of_terms[1]);
    tcp_problem(_P_(C9BadProvides), tck,
        "that asks whether something provides something, and in Inform "
        "'to provide' means that an object (or value) has a property attached - "
        "for instance, containers provide the property 'carrying capacity'. "
        "Here, though, we have %4 rather than the name of a property.");
    return NEVER_MATCH;
}
```

The function PROVISION_KBP_typecheck is called from 5/bp.

§4. Assertion.

```
int PROVISION_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    kind_of_value *kov = NULL;
    property_name *prn = spec_get_property_name_if_any(spec1);
    if (prn) {
        if (spec_is_generic_CONSTANT(spec0)) kov = spec_get_kind_of_value(spec0);
        if (wo0) kind_provides_property(wo0, prn);
        else if (kov) kov_provides_property(kov, prn);
        else return FALSE;
        return TRUE;
    }
    return FALSE;
}
```

The function PROVISION_KBP_assert is called from 5/bp.

§5. Compilation. Run-time is too late to change which objects provide what, so this relation can't be changed at compile time.

```
int PROVISION_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch) {
    if (task == TEST_ATOM_TASK) {
        kind_of_value *kov = cind_kind_of_value_of_term(asch->pt0);
        kind_of_value *kovp = cind_kind_of_value_of_term(asch->pt1);
        if (is_kova(kovp, OBJECT_TY)) return FALSE;
        property_name *prn = spec_get_property_name_if_any(asch->pt1.constant);
        if (prn) {
            if (is_kova(kov, OBJECT_TY)) {
                if (prn_is_value_property(prn))
                    sch_write_to_existing(asch->schema, "WhetherProvides(*1, false, *2)");
                else
                    sch_write_to_existing(asch->schema, "WhetherProvides(*1, true, *2)");
            } else if ((kov) && (does_kov_provide(kov, prn)))
                sch_write_to_existing(asch->schema, "true");
            else if ((kov) && (does_kov_provide(kov, prn) == FALSE))
                sch_write_to_existing(asch->schema, "false");
            else return FALSE;
            return TRUE;
        }
    }
    return FALSE;
}
```

The function PROVISION_KBP_compile is called from 5/bp.

§6. Problem message text.

```
int PROVISION_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    return FALSE;
}
```

The function PROVISION_KBP_describe_for_problems is called from 5/bp.

Measurement Adjectives 9/madj

Purpose

To define adjectives such as large, wide or roomy, which make implicit comparisons of the size of some numerical property, and which (unlike other adjectives) lead to comparative and superlative forms.

Template interpreter commands

```
1   {-callv:validate_definitions}
```

Definitions

¶1. A typical example would be:

> Definition: A container is roomy if its carrying capacity is 10 or more.

Here the domain of the definition is "container", and we must assign an adjective meaning for "roomy" which involves the comparison of a property (here "carrying capacity") against a threshold value ("10") with a given sign (+1, indicating that we need to be at this threshold or above, not at it or below). We then need to create the comparative form "roomier" as a relation, and the superlative "roomiest" as a phrasal form – not in general an adjective, since its domain is too ambiguous in text such as:

> if the canvas bag is roomiest, ...

which begs the question: roomiest out of what? All containers, or implicitly some subcollection of them? So we avoid the problem by allowing superlatives only when explicitly followed by a domain:

> roomiest container in Heathrow Terminal 5

The word "roomy" is the headword, so called in the lexicography sense – other forms are derived from it but they all appear under "roomy" in the Phrasebook.

The implementation of measurement adjectives is difficult for reasons of timing during NI's run: the names of kinds, properties and values become available at different times; whereas we need the name of the adjective itself to become available very early on. This is why the structure below appears to record a lot of extraneous clutter apparently needed only temporarily during parsing – because parsing does not happen all at once, and partial results have to be parked in the structure after one stage to be picked up at the next.

¶2. Details are held in the following structure:

```
typedef struct measurement_definition {
    struct parse_node *measurement_node;                    where the actual definition is
    struct property_name *prop;                             the property being compared, if any
    int headword;                    and the number of the word being defined (must be single word)
    int property_sign;                                      +1 if it must be >= the threshold, -1 if <=
    int property_threshold;                                 numerical value of threshold
    int property_threshold_evaluated;                       have we evaluated this one yet?
    int property_threshold_w1, property_threshold_w2;       text of threshold value
    int pname_w1, pname_w2;                          text of the name of the property to compare
    int property_schema_written;                            I6 schema for testing written yet?
    int superlative_wn;                                     the word number of the superlative form
    struct adjective_meaning *am_of_mdef;                   which adjective meaning
    MEMORY_MANAGEMENT
} measurement_definition;
```

The structure measurement_definition is private to this section.

Comparative Relations 9/cmpbp

Purpose

When a measurement adjective like "tall" is defined, so is a comparative relation like "taller".

Definitions

¶1. This section handles the `PROPERTY_COMPARISON_KBP` relations. Unlike the other relations to do with property values, these do not correspond exactly with the properties. Some properties, like "carrying capacity", might never be compared with measurement adjectives; others, like "height", might be compared with more than one ("short", "tall").

§**1. Initial stock.** There is no initial stock of these, since there are no value properties yet when Inform starts up.

```
void PROPERTY_COMPARISON_KBP_create_initial_stock(void) {
}
```

The function PROPERTY_COMPARISON_KBP_create_initial_stock is called from 5/bp.

§**2. Second stock.** When an adjective is defined so that it performs an inequality comparison of a property value, like so:

> Definition: A woman is tall if her height is 68 or more.

...Inform automatically generates comparative ("taller") and superlative ("tallest") forms of the adjective being defined. The "or more" tells Inform that having greater height makes someone more tall, rather than less, so that X is "taller than" Y if the height of X is greater than the height of Y. This is handled as a "comparative" relation.

```
void PROPERTY_COMPARISON_KBP_create_second_stock(void) {
    measurement_definition *mdef;
    LOOP_OVER(mdef, measurement_definition) {
        int sign;
        property_name *prn;
        mdef_read_property_details(mdef, &prn, &sign);
        if (prn) validate_mdef(mdef);          make sure definition is otherwise syntactically sound
        if (prn) {
            int headword = mdef_get_headword(mdef);                word number of, e.g., "tall"
            int comparative_form = make_comparative(headword);                          "taller"
            vocabulary_entry *quiddity = lw_array[make_quiddity(headword)].lw_identity;    "tall-
ness"
            i6_schema *schema_to_compare_property_values;
            ⟨Work out property comparison schema 3⟩;
            ⟨Construct a BP named for the quiddity and tested using the comparative schema 4⟩;
        }
    }
}
```

The function PROPERTY_COMPARISON_KBP_create_second_stock is called from 5/bp.

§**3.** The I6 code needed numerically to compare the property values:

⟨Work out property comparison schema 3⟩ ≡

```
char *i6_pname = prn_get_i6_identifier(prn);
char *i6_op;
switch (sign) {
    case 1: i6_op = ">"; break;
    case -1: i6_op = "<"; break;
    default: i6_op = "=="; break;
}
schema_to_compare_property_values =
    sch_new_3("(*1.%s %s *2.%s)", i6_pname, i6_op, i6_pname);
```

This code is used in §2.

§**4.** The BP arising from "tall" would be called the "tallness relation", for instance. Note that we don't say anything about the domain of x and y in $T(x, y)$. That's because we a value property like "height" may exist for more than one kind of object, and there is not necessarily any unifying kind of value K such all objects satisfying K possess a height and all others do not. (That's intentional: it is Inform's one concession towards multiple-inheritance, and it allows containers and doors to share lockability behaviour despite being of mutually incompatible kinds.)

⟨Construct a BP named for the quiddity and tested using the comparative schema 4⟩ ≡

```
binary_predicate *bp;
bp = make_pair_of_BPs(PROPERTY_COMPARISON_KBP,
    bptd_blank(), bptd_blank(),
    vocab_get_exemplar(quiddity, FALSE), NULL, -1, NULL, NULL,
    schema_to_compare_property_values, quiddity);
bp->comparison_sign = sign; bp->comparative_property = prn;
register_comparative_preposition(comparative_form, bp);
```

This code is used in §2.

§5. Typechecking.

```
int PROPERTY_COMPARISON_KBP_typecheck(binary_predicate *bp,
    kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    property_name *prn = kov_get_coinciding_property(kovs_of_terms[1]);
    if ((prn) && (prn != bp->comparative_property)) {
        if (tck->log_to_I6_text)
            LOG("Comparative misapplied to $Y not $Y\n", prn, bp->comparative_property);
        quote_property(4, bp->comparative_property);
        quote_property(5, prn);
        tcp_problem(_P_(C9ComparativeMisapplied), tck,
            "that ought to make a comparison of %4 not %5.");
        return NEVER_MATCH;
    }
    if ((kovs_required[0]) &&
        (can_we_cast_kovs(kovs_of_terms[0], kovs_required[0]) == NEVER_MATCH)) {
        LOG("Term 0 is $u not $u\n", kovs_of_terms[0], kovs_required[0]);
        issue_bp_typecheck_error(bp, kovs_of_terms[0], kovs_of_terms[1], tck);
        return NEVER_MATCH;
    }
    return ALWAYS_MATCH;
}
```

The function PROPERTY_COMPARISON_KBP_typecheck is called from 5/bp.

§6. Assertion.

```
int PROPERTY_COMPARISON_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    return FALSE;
}
```

The function PROPERTY_COMPARISON_KBP_assert is called from 5/bp.

§7. **Compilation.** We need do nothing special: these relations can be compiled from their schemas.

```
int PROPERTY_COMPARISON_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch)
{
    if (task == TEST_ATOM_TASK) {
        kind_of_value *st[2];
        st[0] = cind_kind_of_value_of_term(asch->pt0);
        st[1] = cind_kind_of_value_of_term(asch->pt1);
        if ((can_we_cast_kovs(st[0], kova(OBJECT_TY)) != NEVER_MATCH) &&
            (kov_name_can_coincide_with_property(st[1]))) {
            char *i6_op = NULL;
            property_name *prn = kov_get_coinciding_property(st[1]);
            if (prn) {
                if (bp->comparison_sign == 1) i6_op = ">";
                if (bp->comparison_sign == 2) i6_op = "==";
                if (bp->comparison_sign == -1) i6_op = "<";
                if (i6_op) {
                    sch_write_to_existing_2(asch->schema,
                        "*1.%s %s *2", prn_get_i6_identifier(prn), i6_op);
                    return TRUE;
                }
            }
        }
    }
    return FALSE;
}
```

The function PROPERTY_COMPARISON_KBP_compile is called from 5/bp.

§8. Problem message text.

```
int PROPERTY_COMPARISON_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer)
{
    return FALSE;
}
```

The function PROPERTY_COMPARISON_KBP_describe_for_problems is called from 5/bp.

Value-Property Relations 9/vpbp

Purpose

Each value property has two associated relations, one to set the value for a single holder and the other to compare its value between two holders.

Definitions

¶1. This section handles two different kinds of BP: `PROPERTY_SETTING_KBP` and `PROPERTY_SAME_KBP`.

---

§**1. Initial stock.** There is no initial stock of these, since there are no value properties yet when Inform starts up.

```
void PROPERTY_SETTING_KBP_create_initial_stock(void) {
}
void PROPERTY_SAME_KBP_create_initial_stock(void) {
}
```

The function PROPERTY_SETTING_KBP_create_initial_stock is called from 5/bp.
The function PROPERTY_SAME_KBP_create_initial_stock is called from 5/bp.

§**2. Subsequent creations.** BPs like this lead to a timing problem, because we have to create the relation early enough that we can make sense of the sentences in the source text; but at that early time, the properties haven't been created yet. We therefore store the text of the property name (say, "weight") in `property_pending_w1`, `property_pending_w2` and come back to it later on.

```
binary_predicate *make_set_property_BP(int w1, int w2) {
    binary_predicate *bp = make_pair_of_BPs(PROPERTY_SETTING_KBP,
        bptd_thing(), bptd_blank(),
        "set-property", NULL, -1, NULL, NULL, NULL, NULL);
    bp->property_pending_w1 = w1;
    bp->property_pending_w2 = w2;
    bp->reversal->property_pending_w1 = w1;
    bp->reversal->property_pending_w2 = w2;
    return bp;
}
```

The function make_set_property_BP is called from 5/conj and 9/prop.

§**3.** Meanwhile, we can't look up the BP with reference to the property, since the property may not exist yet; we have to use the text of the name of the property as a key, clumsy as that may seem.

```
binary_predicate *find_set_property_BP(int w1, int w2) {
    binary_predicate *bp;
    LOOP_OVER(bp, binary_predicate)
        if (compare_word_range(w1, w2, bp->property_pending_w1, bp->property_pending_w2))
            if (bp->right_way_round)
                return bp;
    return NULL;
}
```

The function find_set_property_BP is called from 9/prop.

§**4.** ...And now it's "later on". We fix these BPs in original-reversal pairs, so that the two can never fall out of step.

```
void fix_property_bp(binary_predicate *bp) {
    property_name *prn;
    binary_predicate *bpr = bp->reversal;
    int w1 = bp->property_pending_w1, w2 = bp->property_pending_w2;
    if (w1 < 0) return;
    prn = parse_property_name(w1, w2);
    bp->property_pending_w1 = -1; bp->property_pending_w2 = -1;
    bpr->property_pending_w1 = -1; bpr->property_pending_w2 = -1;
    if (prn == NULL) {
        current_sentence = bp->bp_created_at;
        sentence_problem(_P_(C9RelationWithBadProperty),
            "that doesn't seem to be a property",
            "perhaps because you haven't defined it yet?");
        return;
    }
    if (prn_is_either_or(prn)) {
        current_sentence = bp->bp_created_at;
        sentence_problem(_P_(C9RelationWithEitherOrProperty),
            "verbs can only set properties with values",
            "not either/or properties like this one.");
        return;
    }
    bp->set_property = prn; bpr->set_property = prn;
    if (bp->right_way_round) set_property_BP_schemas(bp, prn);
    else set_property_BP_schemas(bpr, prn);
}
```

The function fix_property_bp is called from 8/relv and 9/prop.

§**5. Second stock.** The following is called after all properties have been created, making it the perfect opportunity to go over all of the property-setting BPs:

```
void PROPERTY_SETTING_KBP_create_second_stock(void) {
    binary_predicate *bp;
    LOOP_OVER(bp, binary_predicate)
        if (bp->property_pending_w1 >= 0)
            fix_property_bp(bp);
}
```

The function PROPERTY_SETTING_KBP_create_second_stock is called from 5/bp.

§**6.** Note that we read and write to the property directly, without asking the template layer to check if the given object has permission to possess that property. We can afford to do this because type-checking at compile time guarantees that it does have permission, and as a result we gain some speed and simplicity.

```
void set_property_BP_schemas(binary_predicate *bp, property_name *prn) {
    bp->test_function = sch_new_1("*1.%s == *2", prn_get_i6_identifier(prn));
    bp->make_true_function = sch_new_1("*1.%s = *2", prn_get_i6_identifier(prn));
    bp->term_details[1].implies_kov = prn_get_kind_of_value(prn);
}
```

§**7.** Next, an equality comparison between property values also exists automatically for every value property. If, as in the above example, there is a value property called "height" then a BP is constructed in order to serve as the meaning of "the same height as" in text like this:

if Ms Cregg is the same height as Big Bird, ...

We again have two schemas, because it makes sense not only to perform the comparison but also to force it true thus:

now Ms Cregg is the same height as Big Bird;

(That couldn't be arranged for strict inequality comparisons like "taller than" because it is unclear just how much taller than Big Bird we would have to make C. J.)

```
void PROPERTY_SAME_KBP_create_second_stock(void) {
    property_name *prn;
    LOOP_OVER(prn, property_name) {
        if (prn_is_value_property(prn)) {
            vocabulary_entry *rel_name;
            char *i6_pname = prn_get_i6_identifier(prn);
            ⟨Work out the name for the same-property-value-as relation 8⟩;
            binary_predicate *bp = make_pair_of_BPs(PROPERTY_SAME_KBP,
                bptd_blank(), bptd_blank(),
                vocab_get_exemplar(rel_name, FALSE), NULL, -1, NULL,
                sch_new_2("*1.%s = *2.%s", i6_pname, i6_pname),
                sch_new_2("*1.%s == *2.%s", i6_pname, i6_pname),
                rel_name);
            bp->same_property = prn;
            register_same_property_as_preposition(bp);
        }
    }
}
```

The function PROPERTY_SAME_KBP_create_second_stock is called from 5/bp.

§**8.** In I7 source text, this relation is called "same-height-as", but we don't mention this in the documentation because (for timing reasons) it doesn't exist when the new-verb sentences are being parsed: so writing

> The verb to be level with implies the same-height-as relation.

cannot work. Nothing is really lost by this, since it's easy enough to define an identically-behaving relation by hand:

> Levelling relates a person (called Mr X) to a person (called Mr Y) when the height of Mr X is the height of Mr Y.
>
> The verb to be level with implies the levelling relation.

Relations need to have single-word names, but properties don't, so we shrink spaces to hyphens: thus, for instance, "same-carrying-capacity-as". We also truncate to a reasonable length, ensuring that the result doesn't exceed `MAX_WORD_LENGTH` or overflow our storage for a debugging-log name.

⟨Work out the name for the same-property-value-as relation 8⟩ ≡

```
int w1 = prn->word_ref1, w2 = prn->word_ref2;
int i7_name_wn = lexer_wordcount;
char i7_name[STRING_TOLERANCE_LIMIT + 10];
sprintf(i7_name, "same-");
print_modest_sized_text_to_string(w1, w2, i7_name + strlen(i7_name));
sprintf(i7_name + strlen(i7_name), "-as");
int i; for (i=0; i7_name[i]; i++) if (i7_name[i] == ' ') i7_name[i] = '-';
feed_into_lexer(i7_name, TRUE, FALSE);
rel_name = lw_array[i7_name_wn].lw_identity;
```

This code is used in §7.

§9. Typechecking.

```
int PROPERTY_SETTING_KBP_typecheck(binary_predicate *bp,

int PROPERTY_SAME_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    return FALSE;
}
```

The function PROPERTY_SETTING_KBP_describe_for_problems is called from 5/bp.
The function PROPERTY_SAME_KBP_describe_for_problems is called from 5/bp.

Inferences 9/inf

Purpose

To manage the individual pieces of information gathered, with varying degrees of certainty, from assertion sentences. This is mostly information about which objects have what properties.

9/inf.§6 Inference subjects; §7 Comparing inferences; §8-10 Joining an inference to what is known about an object

Definitions

¶1. NI reads a natural language description of a world. As it runs through, it collects together the assertions made in this description (such as "On the table is a hat"), which are sometimes vague (where is this table?), sometimes imply further facts (the hat cannot be a room, and the table must be a supporter) and are sometimes contradictory (if, for instance, "The hat is in the hatbox" has also been read).

NI must form a model world consistent with the assertions made, in such a way that the designer would not be surprised by what it has done. To avoid surprises, Occam's Razor is applied: the simplest and most likely explanation (likely from the standpoint of interactive fiction) should be assumed.

Information being gathered is not stored in the raw form of assertion sentences like "The portcullis is a door" but in instances of a data structure called an `inference`.

Each inference is associated with a single specific object, even when it also concerns a second object: for instance, the knowledge that going east from room A takes one to room B is an inference associated with A.

¶2. Inferences come in the following types:

```
define ISAROOM_INF 1                    is O a room?
define ISWORN_INF 2                     is O initially worn by someone?
define CONTAINSTHINGS_INF 3             does O contain things?
define PARENTAGE_INF 4                  where is O in the object tree?
define PARENTAGE_HERE_INF 5             described vaguely as "here"?
define FOUNDIN_INF 6                    for backdrop things in many places
define PARTOF_INF 7                     is O a part of another object?
define ARBITRARY_INF 8                  records an arbitrary various-various relation
define VALUEARBITRARY_INF 9             ditto but where one term is a value
define MATCHING_INF 10                  matching property values: used for equivalence relations
define DIRECTION_INF 11                 where do map connections from O lead?
define PROPERTY_INF 12                  what are the properties of O?
define BLINDPROPERTY_INF 13             deletes inferences attached to certain I6 properties
define GLOBAL_INF 14                    what is the initial value of this global variable?
```

¶3. Not all information is positive, or certain. The likelihood of an inference being true is measured on a five-point scale, using the following values:

```
define IMPOSSIBLE_CE -2
define UNLIKELY_CE -1
define UNKNOWN_CE 0
define LIKELY_CE 1
define CERTAIN_CE 2
```

¶4. When a given sentence is being parsed, there is a prevailing mood of certainty or uncertainty about the information implied by it, and this is stored in the following global variable:

```
int prevailing_mood = UNKNOWN_CE;
```

¶5. This is the data structure used to store a single inference. Inferences are generally organised in linked lists, hence the `next` field. When references are not given (for instance the second object, or the property name) they will be NULL in the case of structure pointers, or `-1` in the case of word references.

```
typedef struct inference {
    int inference_type;                                   see above
    int certainty;                                        see above
    struct parse_node *inferred_from;                     from what sentence was this drawn?
    struct world_object *obj_ref1;                        first object referred to
    struct world_object *obj_ref2;                        second object, if any
    struct property_name *pname;                          property referred to, if any
    struct specification *val_ref1;                       first value referred to, if any
    struct specification *val_ref2;                       second value referred to, if any
    struct binary_predicate *bp_ref;                      relationship asserted, for ARBITRARY infs
    int word_ref1, word_ref2;                             property value described here in source
    int indices[2];                                       used when constructing V-to-V relation arrays
    struct inference *next;                               next in list of inferences on same subject
} inference;
```

```
define POSITIVE_KNOWLEDGE_LOOP(inf, wo, type)
    for (inf = wo->knowledge; inf; inf = inf->next)
        if ((inf->inference_type == type) && (inf->certainty > 0))
define KNOWLEDGE_LOOP(inf, wo, type)
    for (inf = wo->knowledge; inf; inf = inf->next)
        if (inf->inference_type == type)
define GENERAL_POSITIVE_KNOWLEDGE_LOOP(inf, infs, type)
    for (inf = *(infs_get_list_head(infs)); inf; inf = inf->next)
        if ((inf->inference_type == type) && (inf->certainty > 0))
define GENERAL_KNOWLEDGE_LOOP(inf, infs, type)
    for (inf = *(infs_get_list_head(infs)); inf; inf = inf->next)
        if (inf->inference_type == type)
```

The structure inference is private to this section.

¶6. An inference subject is a convenient holder for the different concepts in Inform about which inferences can be drawn (at present, objects, values, KOVs, BPs).

```
define WO_INFS 1
define VAL_INFS 2
define KOV_INFS 3
define BP_INFS 4

typedef struct inference_subject {
    int inference_subject_type;                    one of the *_INFS constants above
    struct general_pointer subject;                pointer to specific subject
} inference_subject;
```

The structure inference_subject is private to this section.

---

§**1.** The following routine coins a newly minted inference which is not yet attached to any object: since every inference concerns some object, it will not stay unattached for long.

§**2.** The `prevailing_mood` is an air of certainty or doubt which hangs over the current sentence being read, and applies to all of the inferences drawn from it. If nothing has been said about likelihood, the sentence is assumed to be factually certain.

```
inference *create_inference(int type, int certitude) {
    inference *new_i;
    new_i = CREATE(inference);
    new_i->next = NULL;
    new_i->inference_type = type;
    new_i->obj_ref1 = NULL;
    new_i->obj_ref2 = NULL;
    new_i->bp_ref = NULL;
    new_i->word_ref1 = -1;
    new_i->word_ref2 = -1;
    new_i->pname = NULL;
    new_i->certainty = certitude;
    if (certitude == UNKNOWN_CE) new_i->certainty = CERTAIN_CE;
    new_i->inferred_from = current_sentence;
    new_i->val_ref1 = NULL;
    new_i->val_ref2 = NULL;
    new_i->indices[0] = -1; new_i->indices[1] = -1;
    return new_i;
}

    *ref1 = i->obj_ref1;
    *ref2 = i->obj_ref2;
}
binary_predicate *inf_get_bp(inference *i) {
    return i->bp_ref;
}
void inf_set_bp(inference *i, binary_predicate *bp) {
    i->bp_ref = bp;
}
```

The function create_inference is called from 6/asp, 9/kind, 9/spabp, 9/mapbp, 9/exrel and 9/vpbp.
The function inf_inferred_from is called from 2/prob3, 9/model and 9/cot.
The function inf_get_certainty is called from 8/imp, 9/model, 9/cot and 9/inpw.
The function inf_set_certainty is called from 9/spabp.
The function inf_reverse_certainty is called from 9/prop.
The function inf_set_object_reference is called from 6/asp, 9/spabp and 9/vpbp.
The function inf_set_object_references is called from 9/spabp, 9/mapbp and 9/exrel.
The function inf_get_all_references is called from 9/cot.
The function inf_set_all_references is called from 9/exrel.
The function inf_get_object_reference is called from 9/model, 9/cot and 9/inpw.
The function inf_get_object_references is called from 9/model and 9/cot.
The function inf_get_bp is called from 9/cot.
The function inf_set_bp is called from 9/exrel.

§**3.** This utility routine which looks for the "opposite" property in the linked list of inferences belonging to an object. (This is a property of directions.) Crude, but not time-sensitive, and there seems little point in writing this any better.

```
world_object *get_value_of_opposite_property(world_object *wo) {
    inference *i;
    KNOWLEDGE_LOOP(i, wo, PROPERTY_INF) {
        if (strcmp(lw_array[inf_get_property_name(i)->word_ref1].lw_text, "opposite") == 0)
            return i->obj_ref1;
    }
    return NULL;
}
```

The function get_value_of_opposite_property is called from 8/relv and 9/cot.

§**4.**

```
inference *create_global_inference(inference_subject infs, specification *val) {
    PROTECTED_MODEL_PROCEDURE;
    inference *i = create_inference(GLOBAL_INF, prevailing_mood);
    if (prevailing_mood == UNKNOWN_CE) i->certainty = infs_default_certainty(infs);
    i->val_ref1 = val;
    return i;
}
```

The function create_global_inference is called from 6/equal.

§**5.** Many inferences simply store property values, so we have a convenient routine to create those. But note that in this case, a statement of no explicit likelihood about a kind is taken to be merely "likely", not "certain": thus "The wooden box has capacity 2" is `CERTAIN_CE`, while "A container has capacity 2" is merely `LIKELY_CE`. That difference permits the user to type "A container with capacity 4" without a contradiction arising. Had the original sentence been "A container always has capacity 2", a clash would occur which would cause a Problem to be issued.

```
inference *create_property_inference(inference_subject infs,
    property_name *prn, specification *val) {
    PROTECTED_MODEL_PROCEDURE;
    inference *i = create_inference(PROPERTY_INF, prevailing_mood);
    if (prevailing_mood == UNKNOWN_CE) i->certainty = infs_default_certainty(infs);
    i->pname = prn;
    i->val_ref1 = val;
    if (prn == NULL) internal_error("null property inference");
    return i;
}

void inf_set_property_name(inference *i, property_name *prn) {
    i->pname = prn;
}

property_name *inf_get_property_name(inference *i) {
    return i->pname;
}

specification *inf_get_literal_value(inference *i) {
    return i->val_ref1;
}
```

§**7. Comparing inferences.** The following routine is a little like `strcmp`, the standard C routine for comparing strings, in that it compares two inferences and returns a value useful for sorting algorithms: 0 if equal, positive if `i1 < i2`, negative if `i2 < i1`. As we shall see, inferences are insertion-sorted into their linked lists as they are made, but this comparison is also used to watch out for contradictions which arise: the magnitude of the number returned here is used as an indication of how similar are the questions for which the inferences provide answers. (Once it reaches level 5, we know that the two inferences may be clashing with each other, or may be reiterating each other, or simply providing further certainty.)

There's a lot of crude conversion of pointers to integers here, but it doesn't much matter what ordering is used so long as a definite and unchanging ordering is used.

```
int compare_inferences(inference *i1, inference *i2) {
    pointer_sized_int c;
    property_name *pr1, *pr2;
    if (i1 == i2) return 0;
    if (i1 == NULL) return 1;
    if (i2 == NULL) return -1;
    c = i1->inference_type - i2->inference_type;
    if (c > 0) return 2; if (c < 0) return -2;
    c = ((pointer_sized_int) i1->bp_ref) - ((pointer_sized_int) i2->bp_ref);
    if (c > 0) return 3; if (c < 0) return -3;
    pr1 = i1->pname; pr2 = i2->pname;
    if ((pr1) && (prn_is_either_or(pr1)) &&
        (pr2) && (prn_is_either_or(pr2)) &&
        ((pr1 == prn_either_or_get_negation(pr2)) ||
        (pr2 == prn_either_or_get_negation(pr1)))) pr2 = pr1;
    c = ((pointer_sized_int) pr1) - ((pointer_sized_int) pr2);
    if (c > 0) return 3; if (c < 0) return -3;
    c = ((pointer_sized_int) i1->obj_ref2) - ((pointer_sized_int) i2->obj_ref2);
    if (c > 0) return 4; if (c < 0) return -4;
    if (i1->inference_type == VALUEARBITRARY_INF) {
        c = ((pointer_sized_int) i1->val_ref2) - ((pointer_sized_int) i2->val_ref2);
        if (c > 0) return 4; if (c < 0) return -4;
    }
    c = ((pointer_sized_int) i1->obj_ref1) - ((pointer_sized_int) i2->obj_ref1);
    if (c > 0) return 5; if (c < 0) return -5;
    if (i1->inference_type == VALUEARBITRARY_INF) {
        c = ((pointer_sized_int) i1->val_ref1) - ((pointer_sized_int) i2->val_ref1);
        if (c > 0) return 5; if (c < 0) return -5;
    }
    c = ((pointer_sized_int) i1) - ((pointer_sized_int) i2);
    if (c > 0) return 6; if (c < 0) return -6;
    return 0;
}
```

§8. **Joining an inference to what is known about an object.** As the above will have made clear, it is not altogether easy to join a new inference to the linked list of inferences which belong to an object: we can't simply put it at the end of the list. The following routine looks simple enough, but was a difficult routine to get right.

Note that this is not the only place where contradictions are unearthed: higher-level problems are picked up when we try to construct an object tree which fits the known facts. At this stage, for instance, no objection will be made to inferences which make something both a supporter and a container.

```
void join_inference(inference *i, inference_subject infs) {
    PROTECTED_MODEL_PROCEDURE;
    inference *list;
    inference *prev = NULL;
    inference **list_head;
    int c, d, j, icl, lcl, contradiction_flag;
    if (i == NULL) internal_error("joining null inference");
    list_head = infs_get_list_head(infs);
    if (list_head == NULL) internal_error("joining inference to null subject");
    list = *list_head;
    if (list == NULL) { *list_head = i; i->next = NULL; goto ReportIt; }
    while (list != NULL) {
        c = compare_inferences(i, list);
        d = c; if (d < 0) d = -d;
        icl = i->certainty; if (icl < 0) icl = -icl;
        lcl = list->certainty; if (lcl < 0) lcl = -lcl;
        if (d >= 5) {
            Same inference type, property name, direction
            if (icl != lcl) {
                Then we take the more certain to be true
                if (lcl > icl) {
                    report_inference(i, infs, "discarded (we already know better)");
                    return;
                }
                Cut out previous inference
                i->next = list->next;
                if (prev == NULL) *list_head = i; else prev->next = i;
                report_inference(i, infs, "replaced existing equally certain one");
                return;
            }
            ⟨JI - Do these inferences contradict? 9⟩;
            if ((contradiction_flag) && (icl == 2)) {
            Contradictions are not permitted at "certainty" level
                report_inference(i, infs, "contradiction");
                report_inference(list, infs, "with");

            goto ReportIt;
        }
        prev = list; list = list->next;
    }
    prev->next = i;
    ReportIt:
    report_inference(i, infs, "drawn");
}
```

The function join_inference is called from 6/equal, 6/asp, 9/qty, 9/kind, 9/spabp, 9/mapbp, 9/exrel, 9/prop, 9/madj and 9/vpbp.

§**9.** The following code is used when the new inference, `i`, is dangerously similar (similarity `d` equal to 5 or 6) to an existing one, `list`. It must set `contradiction_flag` to `TRUE` if they in fact conflict. Most inferences essentially convey true/false information, so that they conflict if and only if they have certainties of opposite sign (thus, "usually" contradicts "seldom" and "impossible" contradicts "certain"). However, map direction and property inferences have values attached, and these conflict only if those values are different: moreover, the certainties having opposite sign now makes them uncontradictory after all. The following, after all, do not conflict:

The capacity of the box is 10. The capacity of the box is not 12.

⟨JI - Do these inferences contradict? 9⟩ ≡

```
{ int list_c = list->certainty, inf_c = i->certainty;
    contradiction_flag = FALSE;
    if ((i->inference_type == DIRECTION_INF) && (d == 5))
        contradiction_flag = TRUE;
    if (i->inference_type == GLOBAL_INF) contradiction_flag = TRUE;
    if (i->inference_type == PARENTAGE_INF) {
        if (list->obj_ref1 != i->obj_ref1)
            contradiction_flag = TRUE;
    }
```

```
    if (i->inference_type == PROPERTY_INF) {
        if (d == 5) contradiction_flag = TRUE;
        if ((d == 6) && (i->obj_ref1 == NULL)) {
            if ((i->val_ref1) && (list->val_ref1) &&
                (species_is(i->val_ref1, CONSTANT_SPC)) &&
                (species_is(list->val_ref1, CONSTANT_SPC))) {
                kind_of_value *kov_i, *kov_list;
                if ((i->pname) && (prn_condition_of_which_object(i->pname))) {
                    if (spec_get_constant_quantity_if_any(i->val_ref1) !=
                        spec_get_constant_quantity_if_any(list->val_ref1))
                        contradiction_flag = TRUE;
                } else {
                    kov_i = spec_get_kind_of_value(i->val_ref1);
                    kov_list = spec_get_kind_of_value(list->val_ref1);

        contradiction_flag = (!contradiction_flag);
}
```

This code is used in §8.

§**10.** We keep the debugging log file more than usually well informed about what goes on with inferences, as there is obviously great potential for mystifying bugs if inferences are incorrectly ignored, etc.

```
void report_inference(inference *i, inference_subject infs, char *what_happened) {
    LOGIF(INFERENCES, ":::: %s: $j - $I\n", what_happened, &infs, i);
}
```

Make Model World 9/model

Purpose

Once the assertions have all been read and reduced to inferences, and all the world objects are created, we then have to work out their likely kinds. Mostly this is easy: if we were told that X is on Y, for instance, we can immediately see that Y needs to be a supporter. But we go through a fairly thorough process in order to make sure that every piece of information is considered, even in easy cases, so that any contradiction is caught and reported back. "Creating a program often means that you have to create a small universe" (Donald Knuth).

```

---

§**1. The object tree.** This is the NI representation of the tree structure which objects will eventually have when the final story file is compiled. In other words, `child`, `sibling` and `parent` mean what they mean in Inform 6 terms: they define which objects begin the game contained within which others.

The following routine is the equivalent of the Inform 6 statement "move `wo1` to `wo2`", and moves `wo1` and its children to become the final `sibling` of the `child` of `wo2` (or the only `child` if there are none already). The tree is grown entirely from its root by repeated uses of this one operation. We perform a check that it remains well-founded at all times out of sheerest paranoia, and because time is not critical here.

```
void graft_object(world_object *wo1, world_object *wo2) {
    world_object *cw; int error_found, max_loop;
    LOGIF(OBJECT_TREE, "Grafting $O to be child of $O\n", wo1, wo2);
    if (wo1 == NULL) internal_error("wo1 is null in tree graft");
    if (wo2 == NULL) internal_error("wo2 is null in tree graft");
    if (wo2->object_tree_child == NULL) wo2->object_tree_child = wo1;
    else {
        wo2 = wo2->object_tree_child;
        while (wo2->object_tree_sibling != NULL) wo2 = wo2->object_tree_sibling;
        wo2->object_tree_sibling = wo1;
    }
    cw = wo1->object_tree_parent; max_loop = no_wos_now_existing + 1;
    error_found = FALSE;
    while ((cw != NULL) && (error_found == FALSE)) {
        if (cw == wo1) { error_found = TRUE; break; }
        cw = cw->object_tree_parent;
        max_loop--;
        if (max_loop == 0) break;
    }
```

```
    if (error_found) {
        foundation_problem(_P_(BelievedImpossible), wo1);
        wo1->object_tree_parent->object_tree_child = NULL;
        wo1->object_tree_parent = NULL;
        wo1->object_tree_sibling = NULL;
        wo1->object_tree_child = NULL;
    }
}
```

§**2.** The tree is built in two stages. First, the `parent` of every object is determined (see below); then the following routine is called to build a tree structure conforming to that information, which will of course leave the `parent` fields unchanged, but will arrange different objects with the same parent as siblings.

```
world_object *wo_progenitor(world_object *wo) {
    if (wo == NULL) return NULL;
    if (wo->object_tree_parent) return wo->object_tree_parent;
    return wo->part_of;
}
void build_object_tree(void) {
    world_object *wo, *wo2;
    LOOP_OVER(wo, world_object) {
        int k;
        for (wo2 = wo_progenitor(wo), k=0;
            (wo2) && (k<10000);
            wo2 = wo_progenitor(wo2), k++) {
            if (wo2 == wo) {
                foundation_problem(_P_(C9IllFounded),
                    wo);
                break;
            }
        }
    }
    LOOP_OVER(wo, world_object)
        if (wo->object_tree_parent) graft_object(wo, wo->object_tree_parent);
    if (dl_this(OBJECT_TREE_DA)) log_object_tree();
}
```

§**3. A standard error.** This is a notorious Inform 6 limitation which we shall need to own up to. (It is produced in two different ways below, so is worth its own routine.)

```
void cant_cont_and_supp(parse_node *s1, parse_node *s2, world_object *wo) {
    contradiction_problem(_P_(C9CantContainAndSupport),
        s1, s2, wo,
        "cannot both contain things and support things",
        "which is what you're implying here. If you need both, "
        "the easiest way is to make it either a supporter with "
        "a container attached or vice versa. For instance: "
        "'A desk is here. On the desk is a newspaper. "
        "An openable container called the drawer is part "
        "of the desk. In the drawer is a stapler.'");
}
```

§4. **Contradictions between instance and kind.**

```
void check_compatible_with_kind(world_object *k, world_object *wo,
    inference *wo_inf, property_name *pname, int sign) {
    inference *inf;
    if ((k == NULL) || (k == kind_kind)) return;
    KNOWLEDGE_LOOP(inf, k, PROPERTY_INF) {
        if ((inf_get_property_name(inf) == pname)
            && (sign*inf_get_certainty(inf) == IMPOSSIBLE_CE)) {
            Clash:
            LOG("Checking wo $O compatible with kind $O for property $Y\n",
                wo, k, pname);
            contradiction_problem(_P_(C9InstanceContradiction),
                inf_inferred_from(wo_inf), inf_inferred_from(inf), wo,
                "therefore has to have both states of an either/or property "
                "at once",
                "which is impossible. When a kind's definition says that "
                "something is 'always' true, there is no way to override "
                "that for particular things of the kind.");
            return;
        }
    }
    if (prn_either_or_get_negation(pname)) {
        KNOWLEDGE_LOOP(inf, k, PROPERTY_INF) {
            if ((inf_get_property_name(inf) == prn_either_or_get_negation(pname))
                && (sign*inf_get_certainty(inf) == CERTAIN_CE)) {
                goto Clash;
            }
        }
    }
    check_compatible_with_kind(k->kind, wo, wo_inf, pname, sign);
}
```

§5. **Determining scenery.** This is not quite as easy to do as it looks.

```
int wo_is_scenery(world_object *wo) {
    inference *inf;
    if (wo == NULL) return FALSE;
    property_name *pname = find_property_translating("scenery");
    POSITIVE_KNOWLEDGE_LOOP(inf, wo, PROPERTY_INF) {
        if (inf_get_property_name(inf) == pname) return TRUE;
    }
    if ((wo->kind) && (wo->kind != kind_kind)) return wo_is_scenery(wo->kind);
    return FALSE;
}
```

§6. What goes where.

```
int wo_in_wo(world_object *wo1, world_object *wo2) {
    if ((wo1 == NULL) || (wo2 == NULL)) return FALSE;
    while ((wo1 = wo1->object_tree_parent) != NULL) {
        if (wo1 == wo2) return TRUE;
    }
    return FALSE;
}
```

The function wo_in_wo is called from 7/spec.

§7. Turning inferences into a spatial model. At this point all objects are, of course, created, and they have kinds associated with them if the source text has said explicitly what kind they have: but that is not good enough. It often happens that the source implicitly specifies a kind, and we need to take note. We also need to work out what is contained inside what, and the two tasks are related: if X is on Y, then Y must be a supporter, for instance. The five kinds we need to sort out here are room, container, supporter, door and thing. Doors, moreover, come in two varieties: those accessible from both sides, and those accessible one way only.

Once implications have been considered, all inferences are finally drawn. Inferences will still be needed even after the routine has completed, because they are used when compiling the I6 objects which correspond to the world objects in the tree.

```
/****/ void make_model_world (void) {
    int i, j;
    world_object *wo;
    property_name *prn;
    inference *inf;
    if (wo_yourself == NULL)
        internal_error("The Standard Rules have not defined 'yourself'");
    start_room = NULL;
    start_object = NULL;
    LOOP_OVER(wo, world_object) {
        wo->here_flag = FALSE;
        POSITIVE_KNOWLEDGE_LOOP(inf, wo, PARENTAGE_HERE_INF) {
            wo->here_flag = TRUE;
        }
    }
    LOOP_OVER(wo, world_object)
        if (wo->here_flag == FALSE)
            wo_position(wo);
    LOOP_OVER(wo, world_object)
        if (wo->here_flag)
            wo_position(wo);
    ⟨MMW - Issue error if there is no start room 15⟩;
    ⟨MMW - Issue error if any name contains a comma 16⟩;

}
```

This code is used in §7.

§**9.** We need to know in a quick and easy fashion whether something is a door or not, and similarly for rooms. We cannot simply see if it has kind "door", because its kind might be (say) "revolving door", a putative kind of door. This means we need to recurse back through its kind hierarchy; which is a good opportunity to check that that hierarchy is well-founded, something we ought to do for safety's sake.

⟨MMW - Set room and door flags 9⟩ ≡

```
    wo->room_flag = FALSE;
    if (wo->kind_flag == FALSE) {
        int safety_limit = 30;
        k = wo->kind;
        while ((k != NULL) && (k != kind_kind)) {
            if (k == kind_room) wo->room_flag = TRUE;
            if (k == kind_door) wo->door_flag = TRUE;
            k = k->kind;
            safety_limit--;
            if (safety_limit == 0) {
```

```
            LOG("Object $O has kind hierarchy:\n", wo);
            k = wo->kind;
            for (safety_limit = 0; safety_limit<30; safety_limit++) {
                LOG(" -> kind $O\n", k);
                k = k->kind;
            }
            internal_error("The kind hierarchy is not well-founded.");
        }
    }
}
```

This code is used in §7.

§**10.** If no start room has explicitly been appointed by the source text, the first-created room is elected unopposed.

⟨MMW - Is this the start room? 10⟩ ≡

```
if ((wo->room_flag) && (start_room == NULL)) start_room = wo;
```

This code is used in §7.

§**11.** A lone string as a sentence is a description for a room, but an initial description for an object. Only now can we know which, since we have only just decided whether `wo` is a room or not. We therefore draw the necessary inference.

⟨MMW - Turn descriptive text into an inference 11⟩ ≡

```
if (wo->quoted_appearance != NULL) {
    property_name *pn;
    char *inf_name = NULL;
    int thing_flag = FALSE;
    current_sentence = wo->quoted_appearance_sentence;
    k = wo->kind;
    while ((k != NULL) && (k != kind_kind)) {
        if (k == kind_thing) thing_flag = TRUE;
        k = k->kind;
    }
    if (thing_flag) {
        if (wo_is_scenery(wo)) {
            inference *inf; int dont_infer = FALSE;
            KNOWLEDGE_LOOP(inf, wo, PROPERTY_INF) {
                property_name *prn = inf_get_property_name(inf);
                if (((prn) && (inf_get_certainty(inf) > 0)) &&
                    (strcmp(prn_get_i6_identifier(prn), "description")==0)) {
                    ⟨Produce a problem for doubly described scenery 12⟩;
                    dont_infer = TRUE;
                }
            }
            if (dont_infer == FALSE) inf_name = "description";
        } else inf_name = "initial";
    } else inf_name = "description";
    if (inf_name) {
        pn = find_property_translating(inf_name);
        if (pn == NULL) internal_error("It appears that "
            "no I7 properties have been defined translating "
            "to I6 'description' and 'initial'");
```

```
            assert_property_value_explicitly(pn, wo, NULL, wo->quoted_appearance);
        }
    }
```

This code is used in §7.

§**12.**

⟨Produce a problem for doubly described scenery 12⟩ ≡

```
    object_problem(_P_(C9SceneryDoublyDescribed),
        wo,
        "is scenery, which means that it cannot sensibly have any 'initial "
        "appearance' property - being scenery, it isn't announced when the "
        "player first sees it. That means the quoted text about it has to "
        "be read as its 'description' instead, seen when the player examines "
        "it. But the source text writes out its description, too",
        "which means we have a subtle little contradiction here.");
```

This code is used in §11.

§**13.** Now that all inferences are drawn, we can find out whether `wo` provides a description, and whether it is to be initially carried.

⟨MMW - Set description and initially carried flags 13⟩ ≡

```
    wo->defines_description = FALSE;
    wo->initially_carried = FALSE;
    KNOWLEDGE_LOOP(inf, wo, PROPERTY_INF) {
        property_name *prn = inf_get_property_name(inf);
        if (prn == NULL)
            internal_error("Inference with null property");
        if (inf_get_certainty(inf) > 0) {
            if (strcmp(prn_get_i6_identifier(prn), "description")==0)
                wo->defines_description = TRUE;
            if (strcmp(prn_get_i6_identifier(prn), "initially_carried")==0)
                wo->initially_carried = TRUE;
            if (strcmp(prn_get_i6_identifier(prn), "privately_named")==0)
                wo->nameless = TRUE;
            if ((prn_is_either_or(prn)) &&
                (prn_either_or_get_negation(prn)) &&
                (strcmp(prn_get_i6_identifier(prn_either_or_get_negation(prn)),
                    "privately_named")==0))
                wo->nameless = FALSE;
        }
        if (inf_get_certainty(inf) < 0) {
            if (strcmp(prn_get_i6_identifier(prn), "privately_named")==0)
                wo->nameless = FALSE;
            if ((prn_is_either_or(prn)) &&
                (prn_either_or_get_negation(prn)) &&
                (strcmp(prn_get_i6_identifier(prn_either_or_get_negation(prn)),
                    "privately_named")==0))
                wo->nameless = TRUE;
        }
    }
```

This code is used in §7.

§**14.** This is where we set the `parent` field. We need to split off into a special case for "part of" containment, which is handled by a different tree structure altogether, since it is represented rather differently by the I6 library. Another point of interest is that we can finally interpret the word "here": its meaning ("the most recently created room") is clear enough, but was not possible to decide until we knew what was, and what was not, a room.

⟨MMW - Work out parent object 14⟩ ≡

```
if (wo->kind_flag == FALSE) {
    int component_part = FALSE;

            wo_set_I6_representation(wo, lw_array[p->down->next->next->word_ref1].lw_text);
        }
}
```

The function Inform_name_the_objects is invoked by a command in a `.i6t` template file.

§23. Rough results to the debugging log.

```
void log_brief_picture(void) {
    int i = 0;
    world_object *wo;
    property_name *pname;
    if (dl_this(BRIEF_PICTURE_DA) == FALSE) return;
    LOOP_OVER(wo, world_object) {
        log_world_object(wo);
        i++; if (i%4 == 0) LOG("\n"); else LOG("   ");
    }
    LOG("\n\n");
    LOOP_OVER(pname, property_name) {
        log_property_name(pname);
        LOG("\n");
    }
}
```

The function log_brief_picture is invoked by a command in a `.i6t` template file.

Compile Object Tree 9/cot

Purpose

To write out the I6 object or class schemas as needed, looking through the inferences as needed to find the property values required, and to declare the objects in foundational order, as I6 (unlike I7) requires.

9/cot.§19 Initial time and place; §20 Runtime storage for relations, where needed

    if (wo->object_tree_sibling)
        add_to_object_sequence(wo->object_tree_sibling, depth);
}
```

The function compile_object_tree is invoked by a command in a `.i6t` template file.

§**1.** And here is the actual object definition. The `depth` parameter represents the depth in the tree: 0 means "has no parent" and so on. Recall from the DM4 that an I6 object/class declaration consists of a mandatory header line followed by a series of one or more `class`, `with` or `has` clauses, and that there can be any number of each of these kinds of clause: we will make heavy use of the ability to have more than one `with` clause, in particular.

The most surprising feature of the declarations produced by this routine is that they do not (normally) include `before`, `after` or `life` properties. Nothing actually prevents such things from working (and explicit I6 inclusions can be used to paste them in), but action handling is now the province of the rules engine at run-time, and is *not* handled in an object-oriented way any longer.

```
void compile_object(OUTPUT_STREAM, world_object *wo) {
    int i, j, w1, w2, door_sides, short_named, plural_named, articled, door_to_d;
    world_object *k, *wo2;
    inference *inf;
    property_name *prn, *switched_prn = NULL;
    int depth = wo->I6_definition_depth;
    int words_used = 0;

    LOGIF(OBJECT_COMPILATION, "Compiling object definition for $O\n", wo);

    ⟨CO - Compile object header 2⟩;
    ⟨CO - Compile class clause 3⟩;

    compile_inclusions_for_wo(OUT, wo);                    Any pasted-in inclusions

    ⟨CO - Compile the name property 4⟩;
    ⟨CO - Compile the parse name property 6⟩;
    ⟨CO - Compile path-finding workspace 5⟩;

    ⟨CO - Compile component part information 7⟩;
    ⟨CO - Compile found in information for backdrops 8⟩;
    ⟨CO - Compile grammatical attributes 9⟩;

    ⟨CO - Compile inferred properties and attributes 10⟩;

    compile_permitted_but_unspecified_properties(OUT, wo);
    ⟨CO - Compile action bitmap property 16⟩;

    WRITE(";\n\n");
    wo->rough_array_memory_used = words_used;
    words_used = 0;
    for (k = wo; k && (k!=kind_kind) && (k->kind_flag); k=k->kind)
```

```
        words_used += k->rough_array_memory_used;
    if ((wo->kind_flag) && (wo != kind_kind))
        note_VM_usage("object", wo->word_ref1, wo->word_ref2, NULL, 16+words_used, 0, TRUE);
    LOGIF(OBJECT_COMPILATION, "Compilation of $O complete\n", wo);
}
```

§**2.** For the header syntax, see the DM4. Note that we use the `->` method to indicate parentage for all objects other than directions, where we explicitly specify that they must belong to I6's special "Compass" object. Note also that the "hardwired" short name is intentionally made blank: we always use I6's `short_name` property instead.

⟨CO - Compile object header 2⟩ ≡

```
    if (wo->kind_flag) WRITE("Class "); else WRITE("Object ");
    if ((wo->kind_flag == FALSE) && (wo->kind != kind_direction))
        for (i=0; i<depth; i++) WRITE("-> ");
    WRITE("%s ", wo_get_I6_representation(wo));
    if ((strcmp(wo_get_I6_representation(wo), "selfobj")==0) &&
        (wo->object_tree_parent)) {
        start_object = wo->object_tree_parent;
        start_room = start_object;
        while ((start_room) && (start_room->object_tree_parent))
            start_room = start_room->object_tree_parent;
        if ((start_room) && (start_room->room_flag == FALSE)) {
            object_problem(_P_(C9StartsOutsideRooms),
                start_object,
                "seems to be where the player is supposed to begin",
                "but (so far as I know) it is not a room, nor is it "
                "ultimately contained inside a room.");
        }
    }
    if (wo->kind_flag == FALSE) WRITE("\"\"");
    if (wo->kind == kind_direction) WRITE(" Compass");
    WRITE("\n");
```

This code is used in §1.

§**3.** We specify the class of an instance in the old-fashioned way, so that the same code can be used for both Object and Class schemas.

⟨CO - Compile class clause 3⟩ ≡

```
/*  if (!((strcmp(wo_get_I6_representation(wo), "selfobj")==0) &&
        (qty_initial_value(player_quantity) != wo_yourself) &&
        (qty_initial_value(player_quantity) != NULL))) { */
        if ((wo->kind != NULL) && (wo != kind_kind)) {
            WRITE("class %s\n", wo_get_I6_representation(wo->kind));
            words_used++;
        }
        if (wo->kind_flag == FALSE) place_instance_link(OUT, wo, wo->kind);
```

This code is used in §1.

§**4.** The name property requires special care, partly over I6 eccentricities such as the way that single-letter dictionary words can be misinterpreted as characters (hence the double slash below), but also because something called "your ..." in the source text – "your nose", say – needs to be altered to "my ..." for purposes of parsing during play.

Note that `name` is additive in I6 terms, meaning that its values accumulate from class down to instance: but we prevent this, by only compiling `name` properties for instance objects directly. The practical consequence is that we have to imitate this inheritance when it comes to single-word grammar for things. Recall that a sentence like "Understand "cube" as the block" formally creates a grammar line which ought to be parsed as part of some elaborate `parse_name` property: but that for efficiency's sake, we notice that "cube" is only one word and so put it into the `name` property instead. And we need to perform the same trick for the kinds we inherit from.

⟨CO - Compile the name property 4⟩ ≡

```
if ((wo->kind_flag == FALSE) &&
    (wo != kind_direction) && (wo_is_nameless(wo) == FALSE)) {
    int pw1, pw2;
    words_used++;
    WRITE(" with name ");
    if (wo->word_ref1 >= 0) {
        w1 = wo->word_ref1;
        w2 = wo->word_ref2;
    } else {
        w1 = wo->kind->word_ref1;
        w2 = wo->kind->word_ref2;
    }
    if (wo->creator_plural != NULL) {
        pw1 = wo->creator_plural->word_ref1;
        pw2 = wo->creator_plural->word_ref2;
    } else {
        pw1 = wo->kind->creator_plural->word_ref1;
        pw2 = wo->kind->creator_plural->word_ref2;
    }
    LOGIF(PLURALS,
        "Object $O: <$W>\n", wo, w1, w2);
    LOGIF(PLURALS,
        "Object $O: wo->creator_plural %d, wo->kind->creator_plural %d, pw = <$W>\n",
        wo, (wo->creator_plural)?1:0, (wo->kind->creator_plural)?1:0, pw1, pw2);
    for (j=w1; j<=w2; j++) {
        char *p = lw_array[j].lw_text;
        if ((j==w1) && [[word j == your]]) p = "my";
        isn_compile_dictionary_word(OUT, p, FALSE);
        WRITE(" ");
        words_used++;
    }
    if (wo->creator_plural == NULL)                    see test case C9PluralsFromKind
        for (j=pw1; j<=pw2; j++) {
            int k, additional = TRUE;
            for (k=w1; k<=w2; k++)
                if (compare_word(j, lw_array[k].lw_identity)) additional = FALSE;
            if (additional) isn_compile_dictionary_word(OUT, lw_array[j].lw_text, TRUE);
            WRITE(" ");
            words_used++;
        }
```

```
    wo2 = wo;
    while ((wo2) && (wo2 != kind_kind)) {
        if (wo2->understand_as_this_object)
            gv_take_out_one_word_grammar(OUT, wo2->understand_as_this_object);
        wo2 = wo2->kind;
    }
    WRITE("\n");
}
```

This code is used in §1.

§**5.** Workspace for the path-finding algorithm:

⟨CO - Compile path-finding workspace 5⟩ ≡

```
    WRITE(" with vector 0\n");
    if (wo->room_flag) WRITE(" with room_index -1\n");
    if (wo == kind_room) words_used += 2;
```

This code is used in §1.

§**6.** We attach numbered parse name routines as properties for any object where grammar has specified a need. (By default, this will not happen.)

⟨CO - Compile the parse name property 6⟩ ≡ {

```
    gpr_compile_parse_name_property(OUT, wo, wo->understand_as_this_object);
}
```

This code is used in §1.

§**7.** Component parts are represented in I6 in a rather clumsy way, using the `add_to_scope` property. We create this as needed, and we also set a property not normally found in the I6 library, `component_parent`, to make it possible to see from an object what it is a part of. This is done in order to make it easier to produce responses like "The handle is attached to the door" in reply to commands like "take handle" at run-time.

⟨CO - Compile component part information 7⟩ ≡

```
    if (wo->part_of != NULL)
        WRITE(" with component_parent %s\n",
            wo_get_I6_representation(wo->part_of));
    if (wo->first_part != NULL)
        WRITE(" with component_child %s\n",
            wo_get_I6_representation(wo->first_part));
    if (wo->next_part != NULL)
        WRITE(" with component_sibling %s\n",
            wo_get_I6_representation(wo->next_part));
```

This code is used in §1.

§**8.** The I6 `found_in` property is used both for two-sided doors and for backdrop objects, but we handle two-sided doors separately (see below).

⟨CO - Compile found in information for backdrops 8⟩ ≡ {

```
    int found_in_compiled = FALSE;
    if (wo->kind == kind_region)
        WRITE(" with regional_found_in [; if (TestRegionalContainment(location, %s)) rtrue;
],",
            wo_get_I6_representation(wo));
    if (wo == kind_region) words_used += 2;
    i = FALSE;
    POSITIVE_KNOWLEDGE_LOOP(inf, wo, FOUNDIN_INF) {
        if (inf_get_object_reference(inf) == NULL) {
            WRITE(" with found_in FoundEverywhere,");
            i = TRUE; found_in_compiled = TRUE;
        } else {
            if (wo_of_kind(inf_get_object_reference(inf), kind_region)) i = 2;
        }
    }
    if (i == 2) {
        found_in_compiled = TRUE;
        WRITE(" with found_in [; ");
        POSITIVE_KNOWLEDGE_LOOP(inf, wo, FOUNDIN_INF) {
            if (wo_of_kind(inf_get_object_reference(inf), kind_region))
                WRITE("if (TestRegionalContainment(location, %s)) rtrue; ",
                    wo_get_I6_representation(inf_get_object_reference(inf)));
            else
                WRITE("if (location == %s) rtrue; ",
                    wo_get_I6_representation(inf_get_object_reference(inf)));
        }
        WRITE("],");
    }
    if (i == FALSE) {
        i = FALSE;
        POSITIVE_KNOWLEDGE_LOOP(inf, wo, FOUNDIN_INF) {
            if (i == FALSE) WRITE(" with found_in");
            i = TRUE; found_in_compiled = TRUE;
            WRITE(" %s", wo_get_I6_representation(inf_get_object_reference(inf)));
        }
    }
    if (i) WRITE("\n");
    if ((wo->kind_flag == FALSE) && (wo_of_kind(wo, kind_backdrop)) &&

```

This code is used in §1.

§**13.** Perhaps surprisingly, every Object schema contains a `list_together` property. This is so that arbitrary tricks can be pulled at run-time with the grouping together activity: it imposes a small overhead, but is worth it.

⟨CO - Compile list together property 13⟩ ≡

```
if (wo->kind_flag == FALSE) WRITE("  with list_together 0,\n");
```

This code is used in §1.

§**14.** See the DM4 for details of how to compile one and two-sided doors in I6. Alternatively, take it on trust that there is nothing surprising here.

⟨CO - Compile door-related properties 14⟩ ≡

```
if (wo->door_flag) {
    door_sides = 0;
    if (wo->map_connection_a != NULL) door_sides++;
    if (wo->map_connection_b != NULL) door_sides++;
    if (door_sides == 2) {
        if (door_to_d) {
            object_problem(_P_(C9BothWaysDoor),
                wo, "seems to be a door whose connections have been "
                "given in both of the alternative ways at once",
                "by directly giving its map connections (the normal "
                "way to set up a two-sided door) and also by saying "
                "what is through it (the normal way to set up a one-sided "
                "door). As a door can't be both one- and two-sided at "
                "once, I'm going to object to this.");
        }
        WRITE(" with found_in %s %s,\n",
            wo_get_I6_representation(wo->map_connection_a),
            wo_get_I6_representation(wo->map_connection_b));
        WRITE(" with door_dir [ loc; loc = location;\n"
            "        if (loc == thedark) loc = real_location;\n"
            "        if (loc == %s) return %s; return %s; ],\n",
            wo_get_I6_representation(wo->map_connection_a),
            wo_get_I6_representation(wo->map_direction_b),
            wo_get_I6_representation(wo->map_direction_a));
        WRITE(" with door_to [ loc; loc = location;\n"
            "        if (loc == thedark) loc = real_location;\n"
            "        if (loc == %s) return %s; return %s; ],\n",
            wo_get_I6_representation(wo->map_connection_a),
            wo_get_I6_representation(wo->map_connection_b),
            wo_get_I6_representation(wo->map_connection_a));
    }
    if (door_sides == 1) {
        world_object *backwards = get_value_of_opposite_property(wo->map_direction_a);
        if (backwards)
            WRITE(" with door_dir %s,\n",
                wo_get_I6_representation(backwards));
    }
}
if (wo == kind_door) words_used += 14;
```

This code is used in §1.

§**15.** In I6, a room must have a description, unlike in I7. We give it a dummy description if necessary (i.e., not if it has one already, and not if it inherits one from its kind anyway).

⟨CO - Compile empty description for room if necessary 15⟩ ≡

```
if ((wo->room_flag) && (wo->defines_description == FALSE)) {
    k = wo->kind;
    while ((k != NULL) && (k != kind_kind)) {
        if (k->defines_description) goto DescriptionProvided;
        k = k->kind;
    }
    WRITE(" with description NULL,\n");
    DescriptionProvided: ;
}
if (wo->room_flag) WRITE(" has mark_as_room,\n");
if (wo_of_kind(wo, kind_thing)) WRITE(" has mark_as_thing,\n");
```

This code is used in §1.

§**16.** The action bitmap is an array of bits attached to each object, one for each action, which records whether that action has yet applied successfully to that object. This is used at run-time to handle past tense conditions such as "the jewels have been taken". Note that we give the bitmap in the class definition associated with "thing" to ensure that it will be inherited by all I6 objects of this class, i.e., all I6 objects corresponding to I7 things.

⟨CO - Compile action bitmap property 16⟩ ≡

```
if (((wo->room_flag == FALSE) && (wo->kind_flag == FALSE))
    || (wo == kind_thing)) {
    act_compile_action_bitmap_property(OUT);
}
```

This code is used in §1.

§**17.** Code for a table of names of kinds.

```
void compile_I7_Kind_Name_routine(OUTPUT_STREAM) {
    world_object *wo;
    WRITE("[ I7_Kind_Name k;\n"); INDENT;
    LOOP_OVER(wo, world_object) if ((wo->kind_flag) && (wo != kind_kind)) {
        int w1, w2;
        w1 = wo->word_ref1;
        w2 = wo->word_ref2;
        WRITE("if (k == %s) print \"", wo_get_I6_representation(wo));
        print_raw_text_to_file(w1, w2, OUT);
        WRITE("\";\n");
    }
    OUTDENT; WRITE("];\n");
}
```

The function compile_I7_Kind_Name_routine is invoked by a command in a `.i6t` template file.

§**18.** And code for equivalence classes.

```
void compute_equivalence_partitions(void) {
    int domain_size = 0;
    world_object *wo, *wo2;
    binary_predicate *bp;
    LOOP_OVER(wo, world_object)
        if (wo->allocation_id >= domain_size)
            domain_size = wo->allocation_id+1;
    equivalence_relations_make_singleton_partitions(domain_size);
    LOOP_OVER(wo, world_object) {
        inference *i;
        POSITIVE_KNOWLEDGE_LOOP(i, wo, MATCHING_INF) {
            wo2 = inf_get_object_reference(i);
            bp = inf_get_bp(i);
            equivalence_relation_merge_classes(bp, domain_size, wo->allocation_id, wo2->allocation_id);
        }
    }
}
void place_instance_link(OUTPUT_STREAM, world_object *wo, world_object *k) {
    world_object *wo2; int found = FALSE;
    WRITE("  with IK%d_Link ", k->allocation_id);
    k->instance_list_length++;
    for (wo2 = wo->next_in_I6_order; wo2; wo2 = wo2->next_in_I6_order)
        if ((wo2->kind_flag == FALSE) && (wo_of_kind(wo2, k))) {
            if ((wo2 == wo_yourself) &&
                (qty_initial_value(player_quantity) != NULL) &&

§**4.** The following routine looks at each kind, takes the first word of its name, prefixes "kind" and looks to see if there is a documentation symbol of that name: if there is, it attaches it to the relevant field of the world object. That will be useful when we come to index the kind.

```
void kinds_documentation(void) {
    world_object *wo;
    LOOP_OVER(wo, world_object) if ((wo->kind_flag) && (wo->word_ref1 >= 0)) {
        char temp[128];
        sprintf(temp, "kind_%s", lw_array[wo->word_ref1].lw_text);
        wo->wo_documentation_symbol = dref_validate_if_possible(temp);
    }
}
```

Spatial Map 9/map

Purpose

To fit the map of the rooms in the game into a cubical grid, preserving distances and angles where possible, and then render it as HTML using a grid of icons for the World Index and also as an EPS file.

9/map.¶3-0 Components of the index map; §2 Map reading; §3-9 Phase I: Positioning the rooms in space; §10-14 Phase II: Building the grids; §15-23 Phase III: Plotting

---

Definitions

¶1. The EPS map-maker is really a miniature interpreted programming language in its own right, and here we define that language's data types and variables.

The "mapping parameters" amount to being variables. The following structure defines the type and current value for each variable: see the Inform documentation for details. But note that variables of the same name are held by many different objects in the map, and their values inherited by sub-objects.

```
define INT_MDT 1                                   an integer
define BOOL_MDT 2                                  true or false
define TEXT_MDT 3                                  quoted text
define COL_MDT 4                                   an HTML-safe colour
define FONT_MDT 5                                  the name of a font
define OFF_MDT 6                                   a positional offset in an (x, y) grid

typedef struct plotting_parameter {
    int specified;                                 is it explicitly specified at this scope?
    char *name;                                    name (used only in global scope)
    int parameter_data_type;                       one of the above types (used only in global scope)
    char *string_value;                            string value, if appropriate to this type;
    int numeric_value;                             or numeric value, if appropriate to this type
} plotting_parameter;
```

The structure plotting_parameter is private to this section.

¶2. A set of variables associated with any map object is called a "scope". As implied above, the global scope is special: it contains the default settings passed down to all lower scopes.

define NO_MAP_PARAMETERS 35

```
typedef struct map_parameter_scope {
    struct map_parameter_scope *wider_scope;                    that is, the scope above this
    struct plotting_parameter values[NO_MAP_PARAMETERS];
} map_parameter_scope;

map_parameter_scope global_map_scope = {
    NULL,
    {
        { TRUE, "font", FONT_MDT, "Helvetica", 0 },
        { TRUE, "minimum-map-width", INT_MDT, NULL, 72*5 },
        { TRUE, "title", TEXT_MDT, "Map", 0 },
        { TRUE, "title-size", INT_MDT, NULL, 24 },
        { TRUE, "title-font", FONT_MDT, "<font>", 0 },
        { TRUE, "title-colour", COL_MDT, "000000", 0 },
        { TRUE, "map-outline", BOOL_MDT, NULL, 1 },
        { TRUE, "border-size", INT_MDT, NULL, 12 },
        { TRUE, "vertical-spacing", INT_MDT, NULL, 6 },
        { TRUE, "monochrome", BOOL_MDT, NULL, 0 },
        { TRUE, "annotation-size", INT_MDT, NULL, 8 },
        { TRUE, "annotation-length", INT_MDT, NULL, 8 },
        { TRUE, "annotation-font", FONT_MDT, "<font>", 0 },
        { TRUE, "subtitle", TEXT_MDT, "Map", 0 },
        { TRUE, "subtitle-size", INT_MDT, NULL, 16 },
        { TRUE, "subtitle-font", FONT_MDT, "<font>", 0 },
        { TRUE, "subtitle-colour", COL_MDT, "000000", 0 },
        { TRUE, "grid-size", INT_MDT, NULL, 72 },
        { TRUE, "route-stiffness", INT_MDT, NULL, 100 },
        { TRUE, "route-thickness", INT_MDT, NULL, 1 },
        { TRUE, "route-colour", COL_MDT, "000000", 0 },
        { TRUE, "room-offset", OFF_MDT, NULL, 0 },
        { TRUE, "room-size", INT_MDT, NULL, 36 },
        { TRUE, "room-colour", COL_MDT, "DDDDDD", 0 },
        { TRUE, "room-name", TEXT_MDT, "", 0 },
        { TRUE, "room-name-size", INT_MDT, NULL, 12 },
        { TRUE, "room-name-font", FONT_MDT, "<font>", 0 },
        { TRUE, "room-name-colour", COL_MDT, "000000", 0 },
        { TRUE, "room-name-length", INT_MDT, NULL, 5 },
        { TRUE, "room-name-offset", OFF_MDT, NULL, 0 },
        { TRUE, "room-outline", BOOL_MDT, NULL, 1 },
        { TRUE, "room-outline-colour", COL_MDT, "000000", 0 },
        { TRUE, "room-outline-thickness", INT_MDT, NULL, 1 },
        { TRUE, "room-shape", TEXT_MDT, "square", 0 }
    }
};
```

The structure map_parameter_scope is private to this section.

¶3. Components of the index map. A structure used in building the index map, but not during compilation of the story file. Components are separate areas of map not connected by regular exits. Note that components are three-dimensional and occupy subsets of a grid of integer-valued (x, y, z) positions, where the position of the origin is undefined (and not relevant, since only the location of one room relative to another is important).

The extreme values below specify that the component lies inside the cube with opposing corners (x_0, y_0, z_0) and (x_1, y_1, z_1).

```
typedef struct map_component {
    int extreme_x0, extreme_x1, extreme_y0, extreme_y1, extreme_z0, extreme_z1;
    int x_offset, y_offset, z_offset;                    of the bottom corner from the origin
    int size;                                            number of rooms in this component
    int accuracy;                                        current penalty score for bad placement of rooms
    MEMORY_MANAGEMENT
} map_component;
```

The structure map_component is private to this section.

    return TRUE;
}
```

§**2. Map reading.** The map is read using the `room_exit` routine below, which works out what room the exit leads to (perhaps through a door). It returns either the world-object on the other side, or else `NULL`, and also sets `door_status` to 0 (no door), 1 (standard 2-sided door) or 2 (a 1-sided door, effectively blocking the exit). In all cases except the boring one (`NULL`, no door), the text `exit_title` is set to a suitable element for use as a tool-tip inside an HTML `title` element.

```
int door_status;
char exit_title[256];

void add_words_utf8(int w1, int w2, char *str) {
    int i, j=0, k, charcode;
    for (i=w1; i<=w2; i++) {
        char *p = lw_array[i].lw_rawtext;
        if [[word i == STROKE]] continue;
        if ((i>w1)
            && ((p[1] != 0) || (is_punctuation(p[0]) == FALSE) || (p[0] == '('))
            && ([[word i == OPENBRACKET]] == FALSE))
            str[j++] = ' ';
        for (k=0; p[k]; k++) {
            switch(p[k]) {
                case ' ':
                case '\x0a':
                case '\x0d':
                case '\t':
```

```
                case NEWLINE_IN_STRING:

            sprintf(exit_title+strlen(exit_title), "\"");
        }
    }
    return wo3;
}
```

§3. **Phase I: Positioning the rooms in space.** We assign (x, y, z) coordinates to each room, and calculate the extremal values of each of x, y, z. This is potentially a research-level problem in graph theory or aesthetics, but not the simplistic way we're going to use it isn't.

The first task is to partition the map into components, that is, equivalence classes under the relation $R \sim S$ if either an exit leads from R to S or vice versa. For these purposes, in and out do not count.

```
void set_component_of(world_object *wo, map_component *mc) {
    int i;
    wo->component = mc;
    for (i=0; i<no_directions; i++) {
        if (direction_is_along_lattice(i) == FALSE) continue;
        world_object *to = room_exit(wo, i, FALSE);
        if ((to != NULL) && (to->component != mc)) set_component_of(to, mc);
    }
}
map_component *get_component_of(world_object *wo) {
    world_object *wo2;
    map_component *mc;
    int i, changed;
    if (wo->component != NULL) return wo->component;

§**4.** In establishing the layout, we will score penalty points for each exit which appears wrongly laid out. The score is based primarily on the angular divergence in direction between the known exit direction and the grid direction, and only secondarily on distance anomalies, because when the user typed "the Field is east of the River" no particular distance was implied. In the following calculation of the penalty associated with an exit, we can also set the `move_flag` to have a movement carried out so that the destination is in the "right" place for this exit: but we remember what we did in order that we can undo if necessary.

```
world_object *saved_to; int saved_grid_x, saved_grid_y, saved_grid_z;
void undo_room_move(void) {
    saved_to->grid_x = saved_grid_x;
    saved_to->grid_y = saved_grid_y;
    saved_to->grid_z = saved_grid_z;
}
int locking_mode_engaged = 0;
int exit_penalty(world_object *wo, int exit, int move_flag) {
    int dx, dy, dz, exit_x, exit_y, exit_z, penalty = 0; char *clue;
    float distance, ux, uy, uz;
    world_object *to = room_exit(wo, exit, FALSE);
    if (to == NULL) return 0;
    if (to->room_flag == FALSE) return 0;
    if (locking_mode_engaged > 0) {
        if ((wo->lock_exit_to == to) || (to->lock_exit_to == wo)) return 0;
        if (locking_mode_engaged == 2) {
            world_object *wo2;
            if (to->lock_exit_to) return 0;
            LOOP_OVER(wo2, world_object)
                if (wo2->lock_exit_to == to) return 0;
        }
    }
    find_spatial_offsets(exit, &exit_x, &exit_y, &exit_z, &clue);
    if ((exit_x == 0) && (exit_y == 0) && (exit_z == 0)) return 0;
    dx = to->grid_x - wo->grid_x;
    dy = to->grid_y - wo->grid_y;
    dz = to->grid_z - wo->grid_z;
    if ((dx == 0) && (dy == 0) && (dz == 0)) {
        if (wo == to) return 0;
        penalty = 10000;
    }
    if ((dx == exit_x) && (dy == exit_y) && (dz == exit_z)) return 0;
    if (penalty == 0) {
        distance = sqrt(dx*dx + dy*dy + dz*dz);
        ux = dx/distance; uy = dy/distance; uz = dz/distance;
        penalty += (int)
        (
        100*((exit_x-ux)*(exit_x-ux) + (exit_y-uy)*(exit_y-uy)
            + (exit_z-uz)*(exit_z-uz)) +
        (exit_x-dx)*(exit_x-dx) + (exit_y-dy)*(exit_y-dy) +
        (exit_z-dz)*(exit_z-dz)
        );
    }
    if ((move_flag) && (penalty > 0)) {
        saved_to = to;
```

```
        saved_grid_x = to->grid_x;
        saved_grid_y = to->grid_y;
        saved_grid_z = to->grid_z;
        to->grid_x = wo->grid_x + exit_x;
        to->grid_y = wo->grid_y + exit_y;
        to->grid_z = wo->grid_z + exit_z;
        LOGIF(SPATIAL_MAP, "Moving $O to offset %d %d %d from $O\n",
            to, exit_x, exit_y, exit_z, wo);
    }
    return penalty;
}
```

§**5.** The penalty for a room is the sum of its exit penalties; for a component, it's the sum of its room penalties. We also calculate the smallest squarely oriented cuboid which contains the component.

```
int room_penalty(world_object *wo, int move_flag) {
    int i, total_penalty = 0;
    for (i=0; i<no_directions; i++)
        if (direction_is_along_lattice(i)) {
            int badness = exit_penalty(wo, i, move_flag);
            total_penalty += badness;
        }
    return total_penalty;
}
int component_penalty(map_component *mc, int move_flag) {
    world_object *wo;
    mc->accuracy = 0;
    LOOP_OVER(wo, world_object) {
        if (mc != wo->component) continue;
        mc->accuracy += room_penalty(wo, move_flag);
        if (wo->grid_x < mc->extreme_x0) mc->extreme_x0 = wo->grid_x;
        if (wo->grid_x > mc->extreme_x1) mc->extreme_x1 = wo->grid_x;
        if (wo->grid_y < mc->extreme_y0) mc->extreme_y0 = wo->grid_y;
        if (wo->grid_y > mc->extreme_y1) mc->extreme_y1 = wo->grid_y;
        if (wo->grid_z < mc->extreme_z0) mc->extreme_z0 = wo->grid_z;
        if (wo->grid_z > mc->extreme_z1) mc->extreme_z1 = wo->grid_z;
    }
    return mc->accuracy;
}
```

§**6.** Locking.

```
int move_anything_locked_to(world_object *wo) {
    int chain = 0, exit_x, exit_y, exit_z; char *clue;
    while (wo->lock_exit_to) {
        world_object *wo2 = wo->lock_exit_to;
        wo->grid_x = wo2->grid_x;
        wo->grid_y = wo2->grid_y;
        wo->grid_z = wo2->grid_z;
        find_spatial_offsets(wo->lock_exit, &exit_x, &exit_y, &exit_z, &clue);
        wo->grid_x += exit_x;
        wo->grid_y += exit_y;
        wo = wo2;
        chain++;
        if (chain >= 1000) break;
    }
    return chain;
}
void lock_positions_in_component(map_component *mc) {
    world_object *wo;
    int changes = 0;
    LOOP_OVER(wo, world_object) {
        if (mc != wo->component) continue;
        changes += move_anything_locked_to(wo);
    }
    LOGIF(SPATIAL_MAP,
        "\nComponent locking produced aggregate chain length %d.\n",
        changes);
    LOOP_OVER(wo, world_object) {
        if (mc != wo->component) continue;
        LOGIF(SPATIAL_MAP, "$O is now at (%d,%d,%d)\n",
            wo, wo->grid_x, wo->grid_y, wo->grid_z);
    }
}
```

§**7.** In each component, we repeatedly run an algorithm which searches all exits, counting those which lead to rooms not at the coordinates you would expect. (In the sense that you'd expect the room north from $(0, 0, 0)$ to be at $(0, 1, 0)$, and so on.) For each such exit, the destination room is moved so that it is at the expected coordinates.

If we ran this algorithm indefinitely it would very likely lock up, continually moving rooms back and forth but never solving the problem. So we stop once passes through the whole component are no longer improving the situation, in the sense of reducing the number of "bad" exits.

Imagining the exit penalties as being heat to be dissipated, we speak of this process as a rapid cooling:

```
void cool_component(map_component *mc) {
    int last_off = 1000000, next_off = 0;
    while (TRUE) {
        next_off = component_penalty(mc, TRUE);
        mc->accuracy = next_off;
        if (next_off >= last_off) return;
        last_off = next_off;
```

```
    }
}
```

§**8.** This produces surprisingly adequate results and for many maps (those conformable to cubical grids with symmetrical unit length exits) will be correct. It is guaranteed to terminate, but the final step might increase the penalty. We finish by seeing if small local changes can improve things (looking only one move ahead), and here the penalty is absolutely required to reduce. This we imagine as diffusing heat, hence the name of:

```
void diffuse_component(map_component *mc) {
    world_object *wo;
    int f = TRUE, penalty = mc->accuracy;
    LOGIF(SPATIAL_MAP,
        "\nDiffusion time again, sports fans, and the penalty is %d.\n",
        penalty);
    while (f) {
        f = FALSE;
        LOOP_OVER(wo, world_object) {
            int i;
            if (mc != wo->component) continue;
            LOGIF(SPATIAL_MAP, "Attempting to diffuse $O\n", wo);
            for (i=0; i<no_directions; i++)
                if (direction_is_along_lattice(i))
                    if (exit_penalty(wo, i, TRUE)) {
                        LOGIF(SPATIAL_MAP,
                            "Attempting to diffuse along exit %d from $O\n", i, wo);
                        if ((component_penalty(mc, FALSE)) >= penalty) {
                            undo_room_move();
                            LOGIF(SPATIAL_MAP, "No, that just made things no better\n");
                        } else {
                            f = TRUE;
                            penalty = component_penalty(mc, FALSE);
                            LOGIF(SPATIAL_MAP, "Well, that dropped the penalty to %d\n",
                                penalty);
                        }
                    }
        }
    }
    component_penalty(mc, FALSE);
}
void desperation_moves(map_component *mc) {
    world_object *wo, *wo2;
    AndTryAgain:
    LOOP_OVER(wo, world_object) if (mc == wo->component) {
        LOOP_OVER(wo2, world_object) if ((wo != wo2) && (mc == wo2->component)) {
            if ((wo->grid_x == wo2->grid_x) &&
                (wo->grid_y == wo2->grid_y) &&
                (wo->grid_z == wo2->grid_z)) {
                wo->grid_x++;
                LOGIF(SPATIAL_MAP,
                    "Avoiding collision with $O by shifting $O to the east\n",
                    wo2, wo);
```

```
                goto AndTryAgain;
            }
        }
    }
}
```

§**9.** Having cooled and diffused each component, we now treat them as rigid bodies, but still have to establish their spatial relationship to each other. We do this by laying them out along the x axis so that they can be read left to right in the final HTML display, with the start room always being in the leftmost component: indeed, the start room is always at $(0, 0, 0)$. We ensure that the components do not overlap by the crude method of making their bounding cuboids disjoint, even though this will often mean that there is wasted space on the page. (Thus we do not, for instance, use the trick adopted by the British Ordnance Survey in mapping the outlying island of St Kilda on an inset square of what would otherwise be empty ocean on OS18 *Sound of Harris*, despite its being separated by about 60km from the position shown.)

Finally we calculate the extremal values of x, y and z.

```
int extreme_x0 = 0, extreme_x1 = 0,
    extreme_y0 = 0, extreme_y1 = 0,
    extreme_z0 = 0, extreme_z1 = 0;

int establish_grid_positions(void) {
    map_component *mc, *previous_mc;
    world_object *wo;
    int total_accuracy = 0;

    establish_components();

    LOOP_OVER(mc, map_component) {
        for (locking_mode_engaged=0; locking_mode_engaged<=2; locking_mode_engaged++) {
            lock_positions_in_component(mc);
            cool_component(mc);
        }
        lock_positions_in_component(mc);
        diffuse_component(mc);
        lock_positions_in_component(mc);
        desperation_moves(mc);
        total_accuracy += mc->accuracy;
    }

    previous_mc = NULL;
    LOOP_OVER(mc, map_component) {
        if (previous_mc == NULL) {
            mc->x_offset = 0;
            mc->y_offset = 0;
            mc->z_offset = 0;
        } else {
            mc->x_offset =
                previous_mc->x_offset +
                    previous_mc->extreme_x1 - mc->extreme_x0 + 1;
            mc->y_offset = 0;
            mc->z_offset = 0;
        }
        previous_mc = mc;
    }
```

```
    LOOP_OVER(wo, world_object) if (wo->room_flag) {
        wo->grid_x += wo->component->x_offset;
        wo->grid_y += wo->component->y_offset;
        wo->grid_z += wo->component->z_offset;
        if (wo->grid_x < extreme_x0) extreme_x0 = wo->grid_x;
        if (wo->grid_x > extreme_x1) extreme_x1 = wo->grid_x;
        if (wo->grid_y < extreme_y0) extreme_y0 = wo->grid_y;
        if (wo->grid_y > extreme_y1) extreme_y1 = wo->grid_y;
        if (wo->grid_z < extreme_z0) extreme_z0 = wo->grid_z;
        if (wo->grid_z > extreme_z1) extreme_z1 = wo->grid_z;
    }
    LOOP_OVER(mc, map_component) {
        LOGIF(SPATIAL_MAP, "Map component %d: size %d, "
            "extent (%d...%d, %d...%d, %d...%d), offset (%d,%d,%d)\n",
            mc->allocation_id,
            mc->size,
            mc->extreme_x0, mc->extreme_x1,
            mc->extreme_y0, mc->extreme_y1,
            mc->extreme_z0, mc->extreme_z1,
            mc->x_offset, mc->y_offset, mc->z_offset);
    }
    return total_accuracy;
}
```

§**10. Phase II: Building the grids.** Two three-dimensional arrays are used to store the final spatial representation of the map. Because these are dynamically allocated, we access them by calculating our own array indices. The `map_grid` tells us which world object can be found at (x, y, z), while the `icon_grid` is 25 times larger since it splits each room cell into a 5 by 5 subgrid of icons. Bitmaps stored in the 16 icon cells around the perimeter of the 5 by 5 subgrid tell us which exits to mark (and since we map only 12 kinds of exit, this means that four of them are unused). The central 3 by 3 part of the subgrid is not used: nothing can be plotted there since that's where the room icon goes, which is made not with an image tag but using the HTML table routine below. We will often use the wasteful coordinate system (x, y, z, i_1, i_2) to mean the icon at (i_1, i_2) (with $0 \le i_1, i_2 \le 4$) associated with the room cell at (x, y, z).

The extremal values are the largest and smallest coordinates found anywhere in the model world, and are inclusive. Thus if all six continue to hold the value zero, there can only be one room in the game.

```
world_object **map_grid;
int *icon_grid, *exit_grid;

int posn_3d(int x, int y, int z) {
    return (x-extreme_x0)
        + (y-extreme_y0)*(extreme_x1-extreme_x0+1)
        + (z-extreme_z0)*(extreme_x1-extreme_x0+1)*(extreme_y1-extreme_y0+1);
}

int icon_posn_3d(int x, int y, int z, int i1, int i2) {
    return 25*(posn_3d(x,y,z)) + 5*i1 + i2;
}

int calculate_map_grid(void) {
    world_object *wo;
    int x, overlie = 0;
```

```
    int size_needed =
        (extreme_x1-extreme_x0+1)*
        (extreme_y1-extreme_y0+1)*
        (extreme_z1-extreme_z0+1);
    map_grid = (world_object **)
        (I7_calloc(size_needed, sizeof(world_object *), MAP_INDEX_MREASON));
    for (x=0; x<size_needed; x++) map_grid[x] = NULL;
    icon_grid = (int *)
        (I7_calloc(25*size_needed, sizeof(int), MAP_INDEX_MREASON));
    for (x=0; x<25*size_needed; x++) icon_grid[x] = 0;
    exit_grid = (int *)
        (I7_calloc(25*size_needed, sizeof(int), MAP_INDEX_MREASON));
    for (x=0; x<25*size_needed; x++) exit_grid[x] = -1;
    LOOP_OVER(wo, world_object) if (wo->room_flag) {
        int index = posn_3d(wo->grid_x, wo->grid_y, wo->grid_z);
        if (map_grid[index] != NULL) overlie++;
        map_grid[index] = wo;
    }
    return overlie;
}
```

§**11.** We next define constants needed for the icon bitmap. The information we extract from the map exits is recorded in the low four bits as follows:

```
define EXIT_MAPBIT 1                    An exit leads this way
define DOOR1_MAPBIT 2                   Into a 1-sided door
define DOOR2_MAPBIT 4                   Into a 2-sided door
define ADJACENT_MAPBIT 8                Into the room adjacent in space
define ALIGNED_MAPBIT 16                Into a room in correct direction
define CONNECTIVE_BITMAP 7              AND to test "any connection"
define CORNERDOT_BITMAP 7               Set to 7 to enable corner dots
```

§**12.** The higher bits are used for the nuances which improve the map when several rooms are plotted together. On "pass 2", when individual 1 by 1 room maps are plotted, these nuances distort the picture, so we AND them out.

```
define MEET_MAPBIT 32                   This door should meet the adjacent one
define CROSSDOOR_MAPBIT 64              There's a door on the diagonal athwart
define CROSSDOT_MAPBIT 128              There's a plain exit on ...
define LONGEW_MAPBIT 256
define LONGNS_MAPBIT 512
define OCCUPIED_MAPBIT 1024
define PASS2_BITMAP 15                  AND to remove all plotting nuances
```

§**13.** The following code calculates the low four bits of the icon bitmap grid. Note that the main map grid must already be finished before this stage can even begin.

```
void fill_in_gridsquare(world_object *wo, int exit, int i1, int i2) {

        }
}
```

§**14.** Once the bottom four bits are filled in across the icon bitmap grid, a process called "pair correction" fills in the nuance bits for all adjacent icons representing the same exit. Thus the east side icon of one room may need to be married up with the west side icon of the adjacent room, and so on. The four by four cornices diagonally in between rooms require special care. To plot a northeast exit blocked by a 2-sided door, for instance, requires all four icons to be plotted, but we need to be careful in case the two icons not occupied by the exit are needed for something else (if a northwest exit crossed over it, for instance).

```
void correct_diagonal(int x, int y, int z, int dx) {
    int pos_00, pos_01, pos_10, pos_11, from, to;
    if (dx == 1) {

§**15. Phase III: Plotting.** The icon bitmap grid can be plotted with the following routines, which convert the bitmap to a systematic family of icon names and compile the necessary HTML tag. These icons are associated with exits for the most part, so tool-tips are compiled using the `room_exit` routine. (The notional return value of which we ignore here: it's the side-effect of setting the titling text that we want.)

```
void plot_map_icon(char *icon_name, char *tool_tip) {
    INDEX("<img border=0 src=inform:/map_icons/%s.png %s>",
        icon_name, tool_tip);
}
int mapping_pass;
void plot_map_cell(int x, int y, int z, int i1, int i2, int faux_exit) {
    char icon_name[32]; char *tool_tip = "";
    int bitmap = icon_grid[icon_posn_3d(x, y, z, i1, i2)];
    if (mapping_pass == 2)
        bitmap &= PASS2_BITMAP;
    if (bitmap == 0) {
        if ((i1 == 1) || (i1 == 3)) sprintf(icon_name, "blank_ns");
        else {
            if ((i2 == 1) || (i2 == 3)) sprintf(icon_name, "blank_ew");
            else sprintf(icon_name, "blank_square");
        }
    } else {
        char *addendum = "";
        char *clue = "error";
        if (bitmap & DOOR2_MAPBIT) {
            addendum = "_door";
            if (bitmap & MEET_MAPBIT) addendum = "_door_meet";
        }
        if (bitmap & DOOR1_MAPBIT) addendum = "_door_blocked";
        if (bitmap & CROSSDOOR_MAPBIT) addendum = "_corner_door";
        if (bitmap & CROSSDOT_MAPBIT) addendum = "_dot";
        int exit_x, exit_y, exit_z, exit;
        exit = exit_grid[icon_posn_3d(x, y, z, i1, i2)];
        find_spatial_offsets(exit, &exit_x, &exit_y, &exit_z, &clue);
```

```
        if (*clue == 0) find_spatial_offsets(faux_exit, &exit_x, &exit_y, &exit_z, &clue);
        sprintf(icon_name, "%s_arrow%s", clue, addendum);
        room_exit(map_grid[posn_3d(x, y, z)], exit, TRUE);
        tool_tip = exit_title;
    }
    plot_map_icon(icon_name, tool_tip);
}
```

§**16.** The following routine renders the square icons for the rooms themselves, which are bordered and coloured single-cell tables. The start room is coloured differently from the rest; at some stage I hope to make dark rooms, well, darker. The letters inside are up to two capitalised initials, so East Ballroom becomes EB.

```
define ROOM_SQUARE_SIZE 27
define ROOM_INTERIOR_WIDTH 27
define ROOM_INTERIOR_HEIGHT 25
define ROOM_BORDER_SIZE 1
define LINK_SIZE 13
define BLANK_COLOUR "ffffff"
define ROOM_BORDER_COLOUR "000000"

        INDEX("</font></a>");
    }
    INDEX("</font></td></tr></table>\n");
}
```

§**17.** Key to the regions:

```
void add_region_key(void) {
    world_object *reg; int rcount = 0;
    LOOP_OVER(reg, world_object)
        if (wo_of_kind(reg, kind_region))
            rcount += add_key_for(reg);
    if (rcount > 0) rcount += add_key_for(NULL);
    if (rcount > 0) INDEX("<hr><p>");
}

int add_key_for(world_object *reg) {
    int count = 0, rcount = 0;
    world_object *wo;
    LOOP_OVER(wo, world_object) {
        if ((wo_of_kind(wo, kind_room)) && (wo->in_region == reg)) {
            if (count++ == 0) {
                begin_plain_html_table(ifl);
                INDEX("<tr><td width=\"40\" valign=\"middle\" align=\"left\">");
                index_room_square(wo, 1);
                INDEX("</td><td valign=\"middle\" align=\"left\">");
                INDEX("<font %s>", DEFAULT_HTML_FONT);
                INDEX("<b>");
                if (reg) print_raw_text_to_file(reg->word_ref1, reg->word_ref2, ifl);
                else INDEX("<i>Not in any region</i>");
                INDEX("</b>: ");
                rcount++;
            } else {
                INDEX(", ");
            }
            print_raw_text_to_file(wo->word_ref1, wo->word_ref2, ifl);
        }
    }
    if (count > 0) { end_html_row(ifl); end_html_table(ifl); INDEX("<p>"); }
    return rcount;
}
```

The function add_region_key is called from 9/inpw.

§**18.** The map is composed of exit icons and room squares, and we have seen routines to make both elements, so it remains only to assemble them in an HTML framework sufficiently inflexible to force them into adjacencies. Our main routine plots a map of a rectangular X-Y area at a given fixed Z coordinate. The pass is 1 for the main mapping, 2 for single-room-only mapping lower down on the index page.

```
int map_tables_begun = 2;

§23.

```
void write_eps_file(void) {
    STREAM EPS_struct; STREAM *EPS = &EPS_struct;
    char *fn = build_filename(EPSMAP_LEAFNAME);
    if (write_eps_to_desktop) fn = filename_of_epsfile;
    if (STREAM_OPEN_TO_FILE(EPS, fn, ISO_ENC) == FALSE)
        fatal_error2("Can't open EPS map file", fn);
    eps_map(EPS);
    STREAM_CLOSE(EPS);
}
```

The function write_eps_file is called from 9/inpw.

Temporal Map 9/tmap

Purpose

Parallel to the World index of space is the Scenes index of time, and in this section we render it as HTML.

Template interpreter commands

```
1  {-callv:index_page_Scenes}
```

---

§**1.** The mapping of time is on the one hand simpler than the mapping of space since there is only one dimension, but on the other hand more complex since scenes can be multiply present at the same instant of time (whereas rooms cannot be multiply present at the same point in space). We resolve this with a notation which takes a little bit of on-screen explanation, but seems natural enough to learn in practice.

```

        for (j=1; j<sc->no_ends; j++) index_scene_end(sc, j);
        INDEX("<p><hr><p>");
    }
```

This code is used in §1.

10 An Intangible Miscellany

`10/qnbp`: *Quasinumeric Relations.w* To define the binary predicates corresponding to numerical comparisons.

`10/str`: *String Constants.w* In this section we compile I6 values for the specifications `VALUE/TEXT` and `VALUE/QUOT`.

`10/list`: *List Constants.w* In this section we compile I6 arrays for constant lists arising from braced literals like "1,2,3".

`10/tab`: *Tables.w* To manage and compile tables, which are two-dimensional arrays with associative look-up facilities provided at run-time.

`10/eqns`: *Equations.w* To manage and compile equations, which relate numerical quantities.

`10/libp`: *Listed-In Relations.w* To define the binary predicates corresponding to table columns, and which determine whether a given value is listed in that column.

`10/ifid`: *Interactive Fiction ID.w* Computes and makes available the IFID (Interactive Fiction ID) number for an Inform-generated work of IF, in compliance with the Treaty of Babel.

`10/bib`: *Bibliographic Data.w* To manage the special quantities providing bibliographic data on the work of IF being generated (title, author's name and so forth); to write the iFiction record for the work of IF compiled, its release instructions and its picture manifest, if any.

`10/fig`: *Figures.w* To register the names associated with picture resource numbers, which are defined to allow the final story file to display pictures, and to produce the thumbnail index of figures.

`10/sfx`: *Sound Effects.w* To register the names associated with sound resource numbers, which are defined to allow the final story file to play sound effects, and to produce the index of sound effects.

`10/exf`: *External Files.w* To register the names associated with external files, and build the small I6 arrays associated with each.

`10/isin`: *Inform 6 Inclusions.w* To include Inform 6 code almost verbatim in the output of NI, as instructed by low-level Inform 7 sentences.

Quasinumeric Relations 10/qnbp

Purpose

To define the binary predicates corresponding to numerical comparisons.

Definitions

¶1. The inequality relations $<$, $>$, $\leq$, and $\geq$, which can be applied not only to numbers but also to units (height, length and so on).

It might seem redundant to define both `a_gt_b_predicate` (which makes the numerical test $a > b$) and also `a_lt_b_predicate` (which tests $a < b$). Why not define only one, and get the other meaning free as its reversal? The answer is that is more convenient not to, because it allows us to give both of them names.

There is no numerical equality relation $=$ as such: numbers use the same equality BP as everything else.

```
binary_predicate *a_gt_b_predicate = NULL;
binary_predicate *a_lt_b_predicate = NULL;
binary_predicate *a_ge_b_predicate = NULL;
binary_predicate *a_le_b_predicate = NULL;
```

§1. Initial stock.

These relations are all hard-wired in.

```
void QUASINUMERIC_KBP_create_initial_stock(void) {
    bp_term_details number_term = bptd_new(NULL, kova(NUMBER_TY));
    a_gt_b_predicate =
        make_pair_of_BPs(QUASINUMERIC_KBP,
            number_term, number_term,
            "greater-than", NULL, -1, NULL, NULL, sch_new("*1 > *2"),
            numerically_greater_than_V);
    a_lt_b_predicate =
        make_pair_of_BPs(QUASINUMERIC_KBP,
            number_term, number_term,
            "less-than", NULL, -1, NULL, NULL, sch_new("*1 < *2"),
            numerically_less_than_V);
    a_ge_b_predicate =
        make_pair_of_BPs(QUASINUMERIC_KBP,
            number_term, number_term,
            "at-least", NULL, -1, NULL, NULL, sch_new("*1 >= *2"),
            numerically_greater_than_or_equal_to_V);
    a_le_b_predicate =
        make_pair_of_BPs(QUASINUMERIC_KBP,
            number_term, number_term,
            "at-most", NULL, -1, NULL, NULL, sch_new("*1 <= *2"),
            numerically_less_than_or_equal_to_V);
}
```

The function QUASINUMERIC_KBP_create_initial_stock is called from 5/bp.

§2. **Second stock.** There is none – this is a family of relations which is all built in.

```
void QUASINUMERIC_KBP_create_second_stock(void) {
}
```

The function QUASINUMERIC_KBP_create_second_stock is called from 5/bp.

§3. **Typechecking.**

```
int QUASINUMERIC_KBP_typecheck(binary_predicate *bp,
        kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    if ((can_we_cast_kovs(kovs_of_terms[0], kovs_of_terms[1]) == NEVER_MATCH) &&
        (can_we_cast_kovs(kovs_of_terms[1], kovs_of_terms[0]) == NEVER_MATCH)) {
        if (tck->log_to_I6_text)
            LOG("Unable to apply inequality of $u and $u\n", kovs_of_terms[0], kovs_of_terms[1]);
        quote_kov(4, kovs_of_terms[0]);
        quote_kov(5, kovs_of_terms[1]);
        tcp_problem(_P_(C10InequalityFailed), tck,
            "that would mean comparing two kinds of value which cannot mix - "
            "%4 and %5 - so this must be incorrect.");
        return NEVER_MATCH;
    }
    return ALWAYS_MATCH;
}
```

The function QUASINUMERIC_KBP_typecheck is called from 5/bp.

§4. **Assertion.** These relations cannot be asserted.

```
int QUASINUMERIC_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    return FALSE;
}
```

The function QUASINUMERIC_KBP_assert is called from 5/bp.

§5. **Compilation.** We need do nothing special: these relations can be compiled from their schemas.

```
int QUASINUMERIC_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch) {
    return FALSE;
}
```

The function QUASINUMERIC_KBP_compile is called from 5/bp.

§6. **Problem message text.**

```
int QUASINUMERIC_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    return FALSE;
}
```

The function QUASINUMERIC_KBP_describe_for_problems is called from 5/bp.

String Constants 10/str

Purpose

In this section we compile I6 values for the specifications `VALUE/TEXT` and `VALUE/QUOT`.

10/str.¶2-0 Modes used in compiling literal text

Template interpreter commands

```
9   {-callv:compile_string_constants}
10   {-callv:compile_text_routines}
10   {-callv:allow_no_further_text_subs}
```

Definitions

¶1. Literal text constants need to be stored up, because we will want to choose their ordering. In the Z-machine, strings are referred to by their packed addresses, and I6 always compiles them in order of creation. If we are careful, we can arrange the I6 output of NI such that they are created in alphabetical order: then a simple unsigned comparison of packed addresses at run-time is equivalent to an alphabetical comparison of the text. (We make great use of this when sorting tables.) We can also ensure that two literal texts with the same contents are indeed equal: I6 would have compiled two citations of the same text to two different copies with different packed addresses, so that a numerical comparison of addresses would have failed.

The "literal type" alluded to below is one of `TEXT_TY` for plain text, `QUOT_TY` for raw text used in I6-style boxed quotations and `TEXT_ROUTINE_TY` for text with substitutions (which will need to be printed by a routine).

```
define RED_NODE 1
define BLACK_NODE 2

typedef struct literal_text {
    int word_ref1;                                  position in the source of quoted text
    int literal_type;                               one of the three type values above
    int bibliographic_conventions;                  mostly for apostrophes
    int node_colour;                                red or black: see above
    struct literal_text *left_node;                 within their red-black tree
    struct literal_text *right_node;
    MEMORY_MANAGEMENT
} literal_text;

literal_text *root_of_literal_text = NULL;
literal_text *z_node = NULL;
```

The structure literal_text is private to this section.

¶2. Modes used in compiling literal text. When NI compiles a piece of literal text, it is usually aiming to write this in a notation which I6 will read, which will involve I6 character escapes to render certain exotica: but sometimes it is writing the XML iFiction record instead, which takes a more literal approach to literal text. Hence:

```
int divert_constant_text_bibliographically = FALSE;      Compile literal text more literally
int encode_constant_text_bibliographically = FALSE;      Compile literal text semi-literally
```

¶3. Text containing substitutions, such as "You pick up [the noun] thoughtfully.", are compiled as routines rather than Z-machine strings. Each is stored in one of the following structures. Unlike literal text, a text routine might lead to problem messages when eventually compiled, so it is useful to record the current sentence when a text routine is created: this means a problem can be reported at the right place.

```
typedef struct text_routine {
    int word_ref1, word_ref2;                    text when expanded just prior to compilation
    int wn;                                      position of unexpanded text in the source of quoted text
    struct parse_node *sentence_using_this;      where this occurs in source
    int local_names_existed_at_usage_time;       remember in case of problems
    struct ph_stack_frame *parked_stack_frame;   for cases where possible
    MEMORY_MANAGEMENT
} text_routine;
```

The structure text_routine is private to this section.

¶4. We are only allowed to create new ones until the following is set:

```
int no_further_text_subs = FALSE;
```

¶5. The following global variable records whether we are currently compiling a text routine, rather than some other routine, or free-standing objects.

```
int compiling_text_routines_mode = FALSE;    used for better problem messages
```

---

§**1.** It might be thought that a string constant could be compiled to I6 simply by printing it, but there are three obstacles. Firstly, we need to escape the various escape characters. Secondly, the double-quoted strings used in `box` quotation commands require special handling. And thirdly, we want to achieve a sneaky effect: to ensure that two copies of the same text (other than used for box quotations) always have the same value in the Z-machine, and that their numerical values coincide with alphabetical order when compared as unsigned integers.

Each new string is therefore insertion-sorted into a list in alphabetical order, and given a unique ID number, `X`; then what we compile is the name of an I6 constant, `SC_X`. These constants must be defined later, right at the end of the compilation when we know that all necessary strings have been created and that the list is complete. We achieve the alphabetical ordering by defining the constants in list order, which is not the order of their `X` suffixes.

Quotation texts are instead compiled to routines, also called `SC_X`, which carry out I6 `box` statements.

Insertion-sort has a rather poor running time. At present this does not seem to pose any problem, but if profiling suggests that it is becoming wasteful when I7 source texts become longer, we will probably have to replace it with a red-black tree or similar.

```
literal_text *lt_new(int w1, int colour) {
    literal_text *x = CREATE(literal_text);
    x->left_node = NULL;
    x->right_node = NULL;
    x->node_colour = colour;
    x->word_ref1 = w1;
    x->literal_type = TEXT_TY;
    x->bibliographic_conventions = FALSE;
    return x;
```

```
}
int lt_cmp(int w1, literal_text *lt) {
    if (lt == NULL) return 1;
    if (lt->word_ref1 < 0) return 1;
    return strcmp(lw_array[w1].lw_text, lw_array[lt->word_ref1].lw_text);
}
literal_text *compile_literal_text(OUTPUT_STREAM, int w1) {
    if (divert_constant_text_bibliographically) {
        compile_bibliographic_text(OUT, lw_array[w1].lw_text);
        return NULL;
    }
    if (strcmp(lw_array[w1].lw_text, "\"\"") == 0) {
        WRITE("EMPTY_TEXT_VALUE");
        return NULL;
    }
    if (z_node == NULL) ⟨Initialise the red-black tree 2⟩;
    ⟨Search for the text as a key in the red-black tree 3⟩;
}
```

The function compile_literal_text is called from 7/vasp and 10/bib.

§**2.** For an account of the theory of red-black trees, see Sedgewick, *Algorithms* (2nd edn, chap. 15).

⟨Initialise the red-black tree 2⟩ ≡

```
    z_node = lt_new(-1, BLACK_NODE); z_node->left_node = z_node; z_node->right_node = z_node;
    root_of_literal_text = lt_new(-1, BLACK_NODE);
    root_of_literal_text->left_node = z_node;
    root_of_literal_text->right_node = z_node;
```

This code is used in §1.

§**3.**

⟨Search for the text as a key in the red-black tree 3⟩ ≡

```
    literal_text *x = root_of_literal_text, *p = x, *g = p, *gg = g;
    int went_left = FALSE;                          redundant assignment to appease gcc -O2
    do {
        gg = g; g = p; p = x;
        int sgn = lt_cmp(w1, x);
        if (sgn == 0) ⟨Locate this as the new node 4⟩;
        if (sgn < 0) { went_left = TRUE; x = x->left_node; }
        if (sgn > 0) { went_left = FALSE; x = x->right_node; }
        if ((x->left_node->node_colour == RED_NODE) &&
            (x->right_node->node_colour == RED_NODE))
            ⟨Perform a split 5⟩;
    } while (x != z_node);
    x = lt_new(w1, RED_NODE);
    x->left_node = z_node; x->right_node = z_node;
    if (went_left == TRUE) p->left_node = x; else p->right_node = x;
    literal_text *new_x = x;
    ⟨Perform a split 5⟩;
    x = new_x;
    ⟨Locate this as the new node 4⟩;
```

This code is used in §1.

§4.

⟨Locate this as the new node 4⟩ ≡

```
    if (encode_constant_text_bibliographically) x->bibliographic_conventions = TRUE;
    WRITE("SC_%d", x->allocation_id);
    return x;
```

This code is used in §3.

§5.

⟨Perform a split 5⟩ ≡

```
    x->node_colour = RED_NODE;
    x->left_node->node_colour = BLACK_NODE;
    x->right_node->node_colour = BLACK_NODE;
    if (p->node_colour == RED_NODE) ⟨Rotations will be needed 6⟩;
    root_of_literal_text->right_node->node_colour = BLACK_NODE;
```

This code is used in §3.

§6.

⟨Rotations will be needed 6⟩ ≡

```
    g->node_colour = RED_NODE;
    int left_of_g = FALSE, left_of_p = FALSE;
    if (lt_cmp(w1, g) < 0) left_of_g = TRUE;
    if (lt_cmp(w1, p) < 0) left_of_p = TRUE;
    if (left_of_g != left_of_p) p = rotate(w1, g);
    x = rotate(w1, gg);
    x->node_colour = BLACK_NODE;
```

This code is used in §5.

§7.

```
literal_text *rotate(int w1, literal_text *y) {
    literal_text *c, *gc;
    if (lt_cmp(w1, y) < 0) c = y->left_node; else c = y->right_node;
    if (lt_cmp(w1, c) < 0) {
        gc = c->left_node; c->left_node = gc->right_node; gc->right_node = c;
    } else {
        gc = c->right_node; c->right_node = gc->left_node; gc->left_node = c;
    }
    if (lt_cmp(w1, y) < 0) y->left_node = gc; else y->right_node = gc;
    return gc;
}
```

§**8.**

```
int extent_of_runtime_quotations_array = 1;                    start at 1 to avoid 0 length
void compile_quotation(OUTPUT_STREAM, int w1) {
    literal_text *lt = compile_literal_text(OUT, w1);
    lt->literal_type = QUOT_TY;
    extent_of_runtime_quotations_array++;
}
```

The function compile_quotation is called from 7/vasp.

§**9.** The above gradually piled up the need for `SC_X` constants/routines, as compilation went on: now comes the reckoning, when we have to declare all of these.

See the DM4 for details of the escape characters used in I6 string constants, which use the at symbol – making the code below slightly unreadable in raw `CWEB` format, because the at-symbol is also the escape character in CWEB: thus, in raw (untypeset) format, a double-at below means a single-at. (If you are reading this in the typeset PDF, then this will have been absorbed and you will see the actual text printed, without the doubling for `CWEB` purposes.) For the avoidance of doubt: in I6, one prints a literal tilde with the sequence of characters "at, at, 1, 2, 6", and that is what is compiled below.

```
void compile_string_constants(OUTPUT_STREAM) {
    traverse_lts(OUT, root_of_literal_text);
}
void traverse_lts(OUTPUT_STREAM, literal_text *lt) {
    if (lt->left_node != z_node) traverse_lts(OUT, lt->left_node);
    if (lt->word_ref1 >= 0) {
        if (lt->literal_type == TEXT_TY) {
            int options;
            WRITE("Constant SC_%d = \"", lt->allocation_id);
            options = ISN_DEQUOTE + ISN_EXPAND_APOSTROPHES;
            if (lt->bibliographic_conventions)
                options += ISN_RECOGNISE_APOSTROPHE_SUBSTITUTION;
            isn_compile_string(OUT, lw_array[lt->word_ref1].lw_text, options);
            WRITE("\";\n");
        } else {
            char *p = lw_array[lt->word_ref1].lw_text;
            WRITE("[ SC_%d;\n", lt->allocation_id); INDENT;
            WRITE("box\n\""); INDENT;
            p++;
            while (*p) {
                if ((*p == '\n') || (*p == '\t') || (*p == '^') || (*p == NEWLINE_IN_STRING))
                    WRITE("\"\n\"");
                else WRITE("%c", *p);
                p++;
            }
            WRITE(";\n");
            OUTDENT; OUTDENT; WRITE("];\n");
        }
    }
    if (lt->right_node != z_node) traverse_lts(OUT, lt->right_node);
}
```

The function compile_string_constants is invoked by a command in a `.i6t` template file.

§10.

```
int text_routine_cue(int wn, ph_stack_frame *phsf) {
    text_routine *tr = CREATE(text_routine);
    if (no_further_text_subs) internal_error("Too late for further text substitutions");

```

The function text_routine_cue is called from 7/vasp.

The function append_text_routine_proviso is called from 2/prob2.

The function compile_text_routines is invoked by a command in a `.i6t` template file.

The function allow_no_further_text_subs is invoked by a command in a `.i6t` template file.

List Constants 10/list

Purpose

In this section we compile I6 arrays for constant lists arising from braced literals like "1,2,3".

Template interpreter commands

```
2   {-callv:compile_list_constants}
2   {-array:ConstantListPointers}
```

Definitions

```
typedef struct literal_list {
    int word_ref1, word_ref2;                  /* position in the source of quoted text */
    struct kind_of_value *entry_kov;           /* i.e., of the entries, not the list */
    int make_flag;                             /* build on initialisation from array */
    int no_entries;
    int compiled_already;
    MEMORY_MANAGEMENT
} literal_list;
```

The structure literal_list is private to this section.

---

§**1.**

```
kind_of_value *kov_list_of(kind_of_value *kov) {
    return kovcon(LIST_OF_TY, kov);
}
```

The function kov_list_of is called from 7/tc.

§2.

```
define FAIL_PLOV
    { if (compile_mode) internal_error("tried to compile malformed constant list");
        else return NULL;
    }

kind_of_value *parse_list_of_values(OUTPUT_STREAM, int w1, int w2, int compile_mode) {
    kind_of_value *kov = NULL, *ekov;
    literal_list *ll;
    int e1 = w1, e2, ne1, ecount = 0, blevel = 0;
    if (w1<0) FAIL_PLOV;
    if (w2<w1) {
        kov = kova(NO_ENTRIES_TY);
    } else {
        LOG("%s list of values $W\n", (compile_mode)?"Compiling":"Parsing", w1, w2);
        while (e1 <= w2) {
            e2 = e1;
            ne1 = -1;
            while (e2 < w2) {
                if [[word e2 == OPENBRACE]] blevel++;
                if [[word e2 == CLOSEBRACE]] blevel--;
                if ([[word e2 == COMMA]] && (blevel == 0)) { ne1 = e2+1; e2--; break; }
                e2++;
            }
            if (e2 < e1) FAIL_PLOV;
            specification *spec = parse_expression(e1, e2, VALUE_EXPCON);

Tables 10/tab

Purpose

To manage and compile tables, which are two-dimensional arrays with associative look-up facilities provided at run-time.

Template interpreter commands

```
3   {-callv:traverse_to_create_tables}
3   {-callv:traverse_to_stock_tables}
3   {-callv:check_tables_for_kind_clashes}
8   {-callv:compile_max_score}
11   {-callv:compile_tables}
11   {-callv:compile_print_table_names}
11   {-callv:index_tables}
```

Definitions

¶1. Arrays of static data are held in columns, which belong to tables. Column names are, in effect, types, since they must be consistently typed even across different tables: if Table A and Table B each have a column called "topmost point", then the contents must have a consistent type in both tables. (This enables the name alone to guarantee the type, and also allows for the tables to be linked.)

The predicate calculus engine often finds conditions equivalent to "if A is a C listed in T": it is efficient to rewrite this in a special predicate *listed-in-C*(A, T), and to do this we need to have a binary predicate associated with each possible table column C.

```
define MAX_COLUMNS_PER_TABLE 20

typedef struct table_column {
    int word_ref1, word_ref2;                          name of column (without "entry" suffix)
    int column_id;                                column ID number (uniquely associated with name)
    struct kind_of_value *kov_stored_in_column;        what kind of value is stored in this column

The structure table is private to this section.

---

§**1.** Tables of data are created in two special passes through the source text: the first finds their names and registers them with the parser, while the second (much later) works out their columns and contents. At some point we also try to find ambiguity problems which might bite us later on.

§**2.** During the main assertions traverse, we simply skip over tables.

```
sentence_handler TABLE_SH_handler = { TABLE_NT, -1, 0, NULL };
```

§**3.** Because we use specialist traverses later on, when we can be certain that all named values are known.

```
void traverse_to_create_tables(void) {
    parse_node *p;
    for (TREE_START(p); p; TREE_NEXT(p))
        if (pn_get_node_type(p) == TABLE_NT)
            new_table(NULL, p);
}
void traverse_to_stock_tables(void) {
    table *t;
    LOOP_OVER(t, table) {
        current_sentence = t->table_created_at;
        examine_table(t);
    }
}
void check_tables_for_kind_clashes(void) {
    table *t;
    LOOP_OVER(t, table) {
        if (t->table_name_w1 >= 0) {
            world_object *k =
                parse_world_object(t->table_name_w1, t->table_name_w2, TRUE);
            if (k) {
                quote_source(1, new_nounphrase_worldly(t->table_name_w1, t->table_name_w2, FALSE));
                handmade_problem(_P_(C10TableCoincidesWithKind));
                issue_problem_segment(
                    "The table name %1 will have to be disallowed "
                    "as it is also the name of a kind, or of the plural "
                    "of a kind. For instance, writing 'Table of Rooms' is "
                    "disallowed - it could lead to great confusion.");
                issue_problem_end();
                return;
            }
        }
    }
}

§**4. Table columns.** These associate column names with value specific types, in such a way that if one table has a column called "score" which is a number, then every table with a "score" column must also store numbers in it: this is to make relational links type-safe. (It's also necessary to make column names independently parsable from table names.)

```

            PN = PN->next;
        }
        finish_this_session_of_parsing();
    }
    LOGIF(TABLE_CONSTRUCTION, "Table data is:\n");
    for (i=0; i<t->no_columns; i++) {
        kind_of_value *kov = t->column_type[i]->kov_stored_in_column;
        LOGIF(TABLE_CONSTRUCTION, "Column %d '$W' kov %s with data:\n$T",
            i, t->column_type[i]->word_ref1, t->column_type[i]->word_ref2,
            kov_get_NI_source_name(kov),
            t->column_data[i]);
        if ((is_kovcon(kov)) &&
            (is_kova(kovcon_get_base(kov), NO_ENTRIES_TY))) {
            table_problem(_P_(C10TableColumnEmptyLists),
                t, NULL, t->column_data[i],
                "In the table %1, the table column %3 seems to consist only "
                "of empty lists. This means that I can't tell what kind of value "
                "it should hold - are they to be lists of numbers, for "
                "instance, or lists of texts, or some other possibility? "
                "Either one of the entries must contain a non-empty list - "
                "so that I can deduce the answer by looking at what is in it - "
```

```
                "or else the column heading must say, e.g., by calling it "
                "'exceptions (list of texts)' with the kind of value in "
                "brackets after the name.",
                "TE15");
        }
    }
}
```

§**6.** Note that the data type of the contents of a table column is something which has to be deduced from observation of what is put into that column, and that it is possible for more than one table to use the same column name: where this happens, we attempt to reconcile the data type of the column to a type which is possible for all values in both tables, and this can in principle widen the type of a column.

```

§**7. Creating individual tables.** The source text declaration of tables is not easy to parse, as tabs are significantly different from spaces or new-lines, for instance – so the ordinary rules about white space are suspended. Tabs divide entries in a row; new-lines divide rows in a paragraph; and the table is terminated by a paragraph break.

If a table is declared as

Table 12 - Chemical Elements

then it can be referred to elsewhere in the source either as "Table 12" or as "Table of Chemical Elements", so both excerpts are registered as meaningful. But it is legal to declare a table with only one of the two forms in any case.

```
table *new_table(table *t, parse_node *PN) {

The function table_column_data_type is called from 9/rsdt.
The function log_table is called from 2/dl.

§8. **The maximum score and rankings table.** A special rule is that if a table is called "Rankings" and contains a column of numbers followed by a column of text, then it is used by the run-time scoring system. This can only happen if we declare it somehow in I6 code, which we do with the constant `RANKING_TABLE`. We also set the `MAX_SCORE` constant equal to the number in the bottom row of the table, which is assumed to be the score corresponding to successful completion and the highest rank.

```
void compile_max_score(OUTPUT_STREAM) {
    table *t;
    LOOP_OVER(t, table) {
        int tn1 = t->table_name_w1, tn2 = t->table_name_w2;
        if ([[tn1, tn2 == rankings]] &&
            (t->no_columns >= 2) &&
            (is_kova(t->column_type[0]->kov_stored_in_column, NUMBER_TY)) &&
            ((is_kova(t->column_type[1]->kov_stored_in_column, TEXT_TY)) ||
            (is_kova(t->column_type[1]->kov_stored_in_column, TEXT_ROUTINE_TY)))) {
            parse_node *PN = t->column_data[0]->down;

§**11. Compiling tables.** At run time, the data in T is essentially stored as a table of column tables, one for each column. A column table begins with a word identifying the table column number (so that two columns both called "price" in different tables will have the same identifying value heading their column tables), together with special bits set to indicate that exotic types of data are stored inside. Thus if `T` has R rows and C columns, the column tables are found at `T-->1`, `T-->2`, ..., `T-->`C. Each column table `C` has its identifying number in `C-->1`, a pointer to its blank bits in `C-->2` and its data in `C-->3`, `C-->4`, ..., `C-->`$(R+2)$.

The contents of a cell are not just its value but also an indication of whether or not it is formally blank, which in effect makes it impossible to store in a single virtual machine word. In practice, though, it is inefficient to look up two parallel structures each time we want to access the cell. So a blank cell is represented as both the value `TABLE_NOVALUE`, chosen so that it is very unlikely ever to occur as a genuine table value, and also as a blank bit set in the blanks bitmap. This makes a negative check – that something is not blank – very quick, since only in the very rare case when the value does coincide with `TABLE_NOVALUE` do we need to check the blanks bitmap. A positive check necessarily takes longer, but this cannot be helped.

With some data types it is possible to prove that `TABLE_NOVALUE` cannot be a legal value, and then the bitmap can be dispensed with, and the column is flagged as not having one. This basically means enumerated types and also object numbers. (The latter are enumerated in the Z-machine but not in Glulx: however, the value chosen – currently `0xDEADCE11` – is such that it can never be

an object reference value in any story file smaller than 3.5 GB, and in practice I6 and I7 are not capable of generating story files above 2 GB in any case.)

Note that tables with only one entry are padded with dummy values `NULL` to prevent I6 from misreading the table declarations as requiring huge numbers of entries.

The following flags are also defined in `Tables.i6t` and must agree with the values given there.

```
define TB_COLUMN_SIGNED 0x4000

The function compile_tables is invoked by a command in a `.i6t` template file.

The function tab_get_I6_representation is called from 9/rsdt and 7/vasp.

The function compile_print_table_names is invoked by a command in a `.i6t` template file.

The function index_tables is invoked by a command in a `.i6t` template file.

The function table_get_identifying_name is called from 2/prob3.

Equations 10/eqns

Purpose

To manage and compile equations, which relate numerical quantities.

Template interpreter commands

```
1   {-callv:traverse_to_create_equations}
6   {-callv:traverse_to_stock_equations}
47   {-callv:compile_equations}
68   {-callv:index_equations}
```

Definitions

¶1. POWERS OF INTEGERS; TEST PROBLEMS

¶2. As with tables, equations are detected early on in Inform's run but not parsed for their contents until later, so we store several word ranges. Also as with tables, each can have a number, a name or both.

```
typedef struct equation {
    int word_ref1, word_ref2;                          the text of the actual equation
    int equation_no_w1, equation_no_w2;                the equation number (if any)
    int equation_name_w1, equation_name_w2;            the equation name (if any)
    int where_w1, where_w2;                            declaration of symbols
    int usage_w1, usage_w2;                            usage notes
    struct parse_node *equation_created_at;            where created in source
    int examined_already;
    struct equation_node *parsed_equation;             and the equation itself (when eventually parsed)
    char eqn_I6_identifier[32];                        an I6 identifier
    struct equation_symbol *symbol_list;               the symbols used
    MEMORY_MANAGEMENT
} equation;
```

The structure equation is private to this section.

¶3. Each equation is allowed to use one or more symbols. Some may correspond to local variables in surrounding code from time to time, but others will be constants, and it's better to think of these as placeholders in the syntax of the equation, not as storage objects like variables. For instance, in

$$E = mc^2$$

we have three symbols: E, m and c. (The 2 does not count.) There might be symbols called m in any number of other equations; if so each instance has its own `equation_symbol` structure.

```
typedef struct equation_symbol {
    char variable_name[16];              C string form of name of the var (not done with words)
    int variable_wn;                                          word number of this name
    struct kind_of_value *var_kov;                  if a variable – must be quasinumerical
    struct specification *var_const;                      if a symbol for a constant value
    int temp_constant;                          is this constant a substitution for one usage only?
    struct equation_symbol *next;                          in the list belonging to the equation
    int local_map;                  local variable number, when being solved in a given stack frame
    MEMORY_MANAGEMENT
} equation_symbol;
```

The structure equation_symbol is private to this section.

¶4. When parsed, the equation is stored as a tree of `equation_node` structures. As usual, the leaves represent symbols or else constants not given symbol status (such as the 2 in $E = mc^2$); the non-leaf nodes represent operations, identified with the same codes as used in "Dimensions" in Chapter 7. Note that the equals sign `=` is itself considered an operation here.Thus:

```
OPERATION_EQN =
    SYMBOL_EQN E
    OPERATION_EQN *
        SYMBOL_EQN m
        OPERATION_EQN ^
            SYMBOL_EQN c
            CONSTANT_EQN 2
```

```
define CONSTANT_EQN 1          a leaf, representing a quasinumerical constant not given a symbol
define SYMBOL_EQN 2                                                  a leaf, representing a symbol
define OPERATION_EQN 3                                       a non-leaf, representing an operation
```

¶5. However, because of the algorithm used to parse the text of the equation into this tree, we also need certain other kinds of node to exist during parsing only. They are syntactic gimmicks, and are forbidden in the final tree.

```
define OPEN_BRACKET_EQN 4
define CLOSE_BRACKET_EQN 5
define END_EQN 6                                  the end (left or right edge, really) of the equation
```

¶6. Another temporary trick in parsing is to distinguish between explicit multiplication, where the source text uses an asterisk `*`, and implicit, as between m and c^2 in $E = mc^2$. We distinguish these so that they can bind with different tightnesses, but both are represented just as `TIMES_OPERATION` nodes in the eventual tree.

```
define IMPLICIT_TIMES_OPERATION 100
```

¶7. And now the equation node structure:

```
define MAX_EQN_ARITY 2                                   at present all operations are at most binary

typedef struct equation_node {
    int eqn_type;                                                              one of the *_EQN values
    int eqn_operation;                                  one of the *_OPERATION values (see "Dimensions.w")
    int enode_arity;                                                                    0 for a leaf
    struct equation_node *enode_operands[MAX_EQN_ARITY];                             the operands
    struct specification *leaf_constant;                                              if e.g. "21"
    struct equation_symbol *leaf_symbol;                                              if e.g. "G"
    struct kind_of_value *enode_kov;                                  result of evaluating this node
    MEMORY_MANAGEMENT
} equation_node;
```

The structure equation_node is private to this section.

---

§**1. Traversing for equations.** Early in Inform's run, the following takes place:

```
sentence_handler EQUATION_SH_handler = { EQUATION_NT, -1, 0, NULL };

void traverse_to_create_equations(void) {
    parse_node *p;
    for (TREE_START(p); p; TREE_NEXT(p))
        if (pn_get_node_type(p) == EQUATION_NT)
            new_equation(p->word_ref1, p->word_ref2, FALSE);
}
```

The function traverse_to_create_equations is invoked by a command in a `.i6t` template file.

§**2.** The above catches all of the named expressions written out in the source text, but not the ones written "inline", in phrases like

> let F be given by F = ma;

Those equations are created by calling `new_equation` direct from the meaning list converter, when the phrase is parsed: such equations are called "anonymous", as they have no name. But in either case, an equation begins here:

```
equation *new_equation(int w1, int w2, int anonymous) {
    equation *eqn;
    LOOP_OVER(eqn, equation)
        if (eqn->equation_created_at == current_sentence)
            return eqn;
    eqn = CREATE(equation);
    eqn->equation_created_at = current_sentence;
    eqn->where_w1 = -1; eqn->where_w2 = -1;
    eqn->usage_w1 = -1; eqn->usage_w2 = -1;
    eqn->parsed_equation = NULL;
    eqn->symbol_list = NULL;
    eqn->examined_already = FALSE;
    isn_compose_identifier(eqn->eqn_I6_identifier, 'E', eqn->allocation_id,
        eqn->equation_name_w1, eqn->equation_name_w2);
    int num1 = -1, num2 = -1, name1 = -1, name2 = -1;
    if (anonymous == FALSE) {
```

```
    ⟨Parse the equation's number and/or name 3⟩;
    ⟨Register any names for this equation 4⟩;
    int i, v1, v2;
    if [[w1, w2 == ... where ... : i --> w1, w2 ... v1, v2]]
        eqn_set_wherewithal(eqn, v1, v2);
}
eqn->equation_no_w1 = num1; eqn->equation_no_w2 = num2;
eqn->equation_name_w1 = name1; eqn->equation_name_w2 = name2;
[[w1, w2 == ... COMMA --> w1, w2]];
eqn->word_ref1 = w1; eqn->word_ref2 = w2;
return eqn;
}
```

The function new_equation is called from 5/mlc.

§**3.** We take the word range (w_1, w_2) and shave off the first line, that is, all the words up to the first line break occurring between words. (Compare the syntax for a table declaration.) This becomes the word range (tw_1, tw_2). We know that this begins with the word "equation", or we wouldn't be here (because the sentence would not have been classed an EQUATION_NT).

⟨Parse the equation's number and/or name 3⟩ ≡

```
int i, j, tw1, tw2;
i = last_word_of_formatted_text(w1, w2, FALSE);
tw1 = w1; tw2 = i; w1 = i+1;
j = is_word_intermediate(HYPHEN_V, tw1, tw2);
if [[tw1, tw2 == ... HYPHEN ... : j --> num1, num2 ... name1, name2]] {
    num1++; if (num1 > num2) { num1 = -1; num2 = -1; }          skip the word "equation"
} else {
    num1 = tw1+1; num2 = tw2;
}
if ((num1 >= 0) &&
    (!([[num1, num2 == ###]] && (vocab_test_flags(num1, NUMBER_MC))))) {
    LOG("num = <$W>, name = <$W>\n", num1, num2, name1, name2);
    sentence_problem(_P_(C10EquationMisnumbered),
        "the top line of this equation declaration seems not to be a "
        "legal equation number or name",
        "and should read something like 'Equation 6', or 'Equation - "
        "Newton's Second Law', or 'Equation 41 - Coulomb's Law'.");
    return NULL;
}
```

This code is used in §2.

§**4.** An equation can be referred to by its number, or by its name. Thus

Equation 64 - Distribution of Cheese

could be referred to elsewhere in the text by any of three names:

equation 64, Distribution of Cheese, Distribution of Cheese equation

⟨Register any names for this equation 4⟩ ≡

```
if (num1 >= 0)
    register_reworded_meaning(EQUATION_MC, 0, equation_V, 0,
        num1, num2, 0, STORE_POINTER_equation(eqn));
if (name1 >= 0) {
    specification *spec = parse_expression(name1, name2, TYPE_OR_VALUE_EXPCON);
    if (spec_is_UNKNOWN(spec) == FALSE) {
        quote_source(1, new_nounphrase_worldly(name1, name2, FALSE));
        handmade_problem(_P_(C10EquationMisnamed));
        issue_problem_segment(
            "The equation name %1 will have to be disallowed as it is text "
            "which already has a meaning to Inform. For instance, creating "
            "an equation called 'Equation - 2 + 2' would be disallowed "
            "because Inform would read '2 + 2' as arithmetic, not a name.");
        issue_problem_end();
    } else {
        register_excerpt_meaning(EQUATION_MC, 0, name1, name2,
            STORE_POINTER_equation(eqn));
        register_reworded_meaning(EQUATION_MC, 0, 0, 0, name1, name2, equation_V,
            STORE_POINTER_equation(eqn));
    }
}
```

This code is used in §2.

§**5.** A "where" clause following an equation defines its symbols, as we shall see. That can be detected in the above parsing process where the equation is displayed, but for anonymous equations occurring inline, the S-parser has to discover it; and the meaning list converter then calls this routine:

```
void eqn_set_wherewithal(equation *eqn, int w1, int w2) {
    eqn->where_w1 = w1; eqn->where_w2 = w2;
}
```

The function eqn_set_wherewithal is called from 5/mlc.

§**6. Parsing equations.** So now it's later on. We can run through all the equations displayed in the source text:

```
void traverse_to_stock_equations(void) {
    equation *eqn;
    LOOP_OVER(eqn, equation) {
        current_sentence = eqn->equation_created_at;
        examine_equation(eqn);
    }
}
```

The function traverse_to_stock_equations is invoked by a command in a `.i6t` template file.

§**7.** And, as with creation, `examine_equation` is called explicitly in the meaning list converter when an equation is found inline. So in all cases, we call the following before we need to use the equation, which runs a three-stage process: parsing the "where..." clause to declare the symbols, then parsing the equation, then type-checking it.

```
void examine_equation(equation *eqn) {
    if (eqn->examined_already) return;
    eqn->examined_already = TRUE;
    if (eqn_declare_symbols(eqn) == FALSE) return;
    eqn->parsed_equation = eqn_parse(eqn);
    LOG("PARSED AS:\n");
    log_equation_node(eqn->parsed_equation);
    if (eqn->parsed_equation == NULL) return;
    if (eqn_typecheck(eqn) == FALSE) log_equation_node(eqn->parsed_equation);
}
```

The function examine_equation is called from 5/mlc.

§**8. Declaring symbols.** For a displayed equation, the following parses the "where..." text, which is expected to declare every symbol occurring in it.

```
int eqn_declare_symbols(equation *eqn) {
    if (eqn->where_w1 < 0) return TRUE;
    int result = eqn_declare_variables_inner(eqn, eqn->where_w1, eqn->where_w2, FALSE);
    equation_symbol *ev;
    for (ev = eqn->symbol_list; ev; ev = ev->next)
        if (ev->var_kov == NULL) {
            if (ev->next == NULL) {
                equation_symbol_problem(_P_(BelievedImpossible),
                    eqn, eqn->where_w1, eqn->where_w2,
                    "each symbol in a equation has to be declared with a kind of "
                    "value or else an actual value. So '...where N = 1701.' or "
                    "'...where N, M are numbers.' would be fine.");
                result = FALSE;
            } else {
                ev->var_kov = ev->next->var_kov;
                ev->var_const = ev->next->var_const;
            }
        }
    return result;
}
```

§**9.** But the following routine is also used with the "where" text supplied in a phrase like so:

> let F be given by Newton's Second Law, where m = 101kg;

In this context the "where" text sets explicit values for symbols occurring in the equation; these are temporary settings only and will not change the equation's behaviour elsewhere.

So the following is called in either permanent mode, when it declares symbols for an equation, or temporary mode, when it gives them temporary assignments. It returns `TRUE` if all went well, or `FALSE` if problem messages had to be issued.

The syntax does in fact require every symbol to be declared as an actual or generic value, and the case where `const_flag` is `NOT_APPLICABLE` arises only when the list is abbreviated thus:

> where F is a force, a = 9.801 m/ss, m1 and m2 are masses;

This is split into four clauses: "F is a force" (variable), "a = 9.801 m/ss" (constant), "m1" (neither) and "m2 are masses" (variable). In a `NOT_APPLICABLE` case, which is allowed only in permanent declarations, the symbol is given the same definition as the one following it – so m1 becomes defined as a mass, too.

```
int eqn_declare_variables_inner(equation *eqn, int w1, int w2, int temp) {
    if (is_list_divided(w1, w2, LOOK_FOR_AND)) {
        int lw1 = left_w1, lw2 = left_w2, rw1 = right_w1, rw2 = right_w2, result = TRUE;
        if (eqn_declare_variables_inner(eqn, lw1, lw2, temp) == FALSE) result = FALSE;
        if (eqn_declare_variables_inner(eqn, rw1, rw2, temp) == FALSE) result = FALSE;
        return result;
    }
    specification *spec = NULL;
    kind_of_value *kov = NULL;
    int x1 = -1, x2 = -1;                          word range of the declared value or kind of value
    int const_flag = FALSE;              declared as a constant (TRUE), a variable (FALSE) or neither?
    ⟨Identify the clause as having the syntax for a constant or variable symbol 10⟩;
    if (const_flag != NOT_APPLICABLE)
        ⟨Find the actual value, or kind of value, which the symbol is to match 11⟩;
    if (temp) ⟨Assign the given value to this symbol on a temporary basis 12⟩
    else eqn_add_symbol(eqn, w1, kov, spec);
    return TRUE;
}
```

§**10.**

⟨Identify the clause as having the syntax for a constant or variable symbol 10⟩ ≡

```
int i;
if [[w1, w2 == ... is ... : i --> w1, w2 ... x1, x2]] const_flag = FALSE;
else if [[w1, w2 == ... are ... : i --> w1, w2 ... x1, x2]] const_flag = FALSE;
else if [[w1, w2 == ... EQUALS ... : i --> w1, w2 ... x1, x2]] const_flag = TRUE;
else if (w1 == w2) const_flag = NOT_APPLICABLE;
else {
    sentence_problem(_P_(C10EquationSymbolMisdeclared),
        "the symbols here are not declared properly",
        "and should each be declared with a kind of value or else an "
        "actual value.");
    return FALSE;
}
if (equation_symbol_legal(w1, w2) == FALSE) {
    equation_symbol_problem(_P_(C10EquationSymbolMalformed), eqn, w1, w2,
        "a symbol in a equation has to be a sequence of one to ten "
        "letters optionally followed by a number from 0 to 99, so "
        "'G', 'm', 'pi' and 'KE1' are all legal symbol names. But "
        "this one is not.");
    return FALSE;
}
```

This code is used in §9.

§**11.** Symbols are allowed to be set equal to kinds of value, but only quasinumerical ones; or to quasinumerical constants; or to global variables which contain quasinumerical values. The latter are included to make it easier for extensions to set up sets of equations for, say, gravity, defining

> The acceleration due to gravity is an acceleration that varies.

and thus letting the extension's user decide how strong gravity is, but still using it in equations:

> let F be given by Newton's Second Law, where a = the acceleration due to gravity;

⟨Find the actual value, or kind of value, which the symbol is to match 11⟩ ≡

```
spec = parse_expression(x1, x2, TYPE_OR_VALUE_EXPCON);
if (spec) {
    if (spec_is_generic_CONSTANT(spec)) {
        if (temp) {
            equation_symbol_problem(_P_(C10EquationSymbolVague), eqn, w1, w2,
                "when an equation is named for use in a 'let' "
                "phrase, any variables listed under 'where...' have "
                "to be given definite values, not just vaguely said "
                "to have particular kinds. Otherwise, I can't do any "
                "calculation with them.");
            return FALSE;
        }
        kov = spec_get_kind_of_value(spec);
        spec = NULL;
    } else kov = spec_evaluates_to(spec);
}
if ((spec) && (spec_is_actual_CONSTANT(spec) == FALSE) &&
    (spec_is_global_variable(spec) == FALSE)) {
```

```
        equation_symbol_problem(_P_(C10EquationSymbolNonValue), eqn, w1, w2,
            "this has neither a kind of value nor an actual value.");
        return FALSE;
    }
    if ((spec == NULL) && (const_flag)) {
        equation_symbol_problem(_P_(C10EquationSymbolEqualsKOV), eqn, w1, w2,
            "'is' should be used, not '=', for a kind of value rather "
            "than an actual value.");
        return FALSE;
    }
    if ((kov) && (kov_quasinumerical(kov) == FALSE)) {
        equation_symbol_problem(_P_(C10EquationSymbolNonNumeric), eqn, w1, w2,
            "this has a kind of value on which arithmetic cannot be done, "
            "so it can have no place in an equation.");
        return FALSE;
    }
```

This code is used in §9.

§**12.** At this point we know the user means the variable named at word `w1` to have the temporary value `spec`, and we have to identify that as one of the symbols:

⟨Assign the given value to this symbol on a temporary basis 12⟩ ≡

```
    equation_symbol *ev;
    for (ev = eqn->symbol_list; ev; ev = ev->next)
        if (strcmp(lw_array[w1].lw_rawtext, ev->variable_name) == 0) {
            if (kov_compare(kov, ev->var_kov) == FALSE) {
                equation_symbol_problem(_P_(C10EquationSymbolBadSub), eqn, w1, w2,
                    "you're using 'where' to substitute something into this "
                    "symbol which has the wrong kind of value.");
            }
            ev->temp_constant = TRUE;
            ev->var_const = spec;
            return TRUE;
        }
    equation_symbol_problem(_P_(C10EquationSymbolSpurious), eqn, w1, w2,
        "when 'where' is used to supply values to plug into a "
        "named equation as part of a 'let' phrase, you can only "
        "supply values for symbols actually used in that equation. "
        "This one doesn't seem to occur there.");
    return FALSE;
```

This code is used in §9.

§**13.** We won't want those temporary assignments hanging around, so once the hurly-burly is done, the following is called:

```
void eqn_remove_temp_variables(equation *eqn) {
    equation_symbol *ev;
    for (ev = eqn->symbol_list; ev; ev = ev->next)
        if (ev->temp_constant) {
            ev->var_const = NULL;
            ev->temp_constant = FALSE;
        }
}
```

§**14.** As we saw, permanent symbol declarations cause `eqn_add_symbol` to be called. But what about the symbols for an inline equation, like this one?

let F be given by F = ma;

These are not explicitly declared. What happens is that any local variable on the current stack frame, whose name could plausibly be that of a symbol, is made into one. Sometimes the locals won't be symbols in the equation at all, but will just have short names and coincidentally hold quasinumeric values; that doesn't matter, because if they're not in the equation, they'll never be used.

```
void equation_declare_local_variables(equation *eqn) {
    declare_local_names_in_current_stack_frame(eqn);
}
```

which calls the following for each current local variable in turn:

```
void equation_declare_local(equation *eqn, int w1, int w2, kind_of_value *kov) {
    if (w1 != w2) return;
    if ((equation_symbol_legal(w1, w2)) && (kov_quasinumerical(kov)))
        eqn_add_symbol(eqn, w1, kov, NULL);
}
```

The function equation_declare_local_variables is called from 5/mlc.
The function equation_declare_local is called from 12/phsf.

§**15.** And that about wraps up symbol declaration, except for the routine which actually declares symbols:

```
void eqn_add_symbol(equation *eqn, int w1, kind_of_value *kov, specification *spec) {
    equation_symbol *ev = CREATE(equation_symbol);
    strcpy(ev->variable_name, lw_array[w1].lw_rawtext);
    ev->var_kov = kov;
    ev->var_const = spec;
    ev->next = NULL;
    if (eqn->symbol_list == NULL) eqn->symbol_list = ev;
    else {
        equation_symbol *f = eqn->symbol_list;
        while ((f) && (f->next)) f = f->next;
        f->next = ev;
    }
    ev->variable_wn = w1;
    ev->temp_constant = FALSE;
    LOG("Declared <%s> with KOV $u, value $S\n", ev->variable_name, kov, spec);
}
```

§**16.** This is where the criterion for being a valid symbol name is expressed: it parses the regular expression `[A-Za-z]?{1,8}\d?{0,2}`.

```
int equation_symbol_legal(int w1, int w2) {
    if (w2 == w1) {
        char *p = lw_array[w1].lw_rawtext;
        int j, letters = 0, digits = 0, name_legal = TRUE;
        for (j=0; p[j]; j++) {
            unsigned int c = p[j];
            if (isdigit(c)) digits++;
            else if (isalpha(c)) { letters++; if (digits > 0) name_legal = FALSE; }
            else name_legal = FALSE;
            if (j >= 13) break;
        }
        if ((letters > 10) || (digits > 2)) name_legal = FALSE;
        return name_legal;
    }
    return TRUE;
}
```

§**17. Equation nodes.** The parsed equation is a tree full of nodes, so we need routines to make and examine them.

```
equation_node *enode_new(int t) {
    equation_node *enode = CREATE(equation_node);
    enode->eqn_type = t;
    enode->eqn_operation = -1;
    enode->enode_arity = 0;
    enode->leaf_constant = NULL;
    enode->leaf_symbol = NULL;
    enode->enode_operands[0] = NULL;
    enode->enode_kov = NULL;
    return enode;
}
```

§**18.** This is how we make the three kinds of enode permitted in the final compiled equation. (The other kinds can be created using `enode_new` directly.)

```
equation_node *enode_new_op(int op) {
    equation_node *enode = enode_new(OPERATION_EQN);
    enode->eqn_operation = op;
    return enode;
}
equation_node *enode_new_symbol(equation_symbol *ev) {
    equation_node *enode = enode_new(SYMBOL_EQN);
    enode->leaf_symbol = ev;
    return enode;
}
equation_node *enode_new_constant(specification *spec) {
    equation_node *enode = enode_new(CONSTANT_EQN);
    enode->leaf_constant = spec;
    return enode;
}
```

§**19.** Being able to log nodes is useful, if only because it's always pretty to watch shift-reduce parsers in action.

```
void log_equation_node(equation_node *tok) {
    log_equation_node_inner(tok, 0);
}
void log_equation_node_inner(equation_node *tok, int d) {
    int i;
    for (i=0; i<d; i++) if (i+1<d) LOG("    "); else LOG("+---");
    if (tok == NULL) LOG("<NULL>\n");
    else if (tok->eqn_type == OPERATION_EQN) {

}
```

§**20. Tokenising equations.** We break up the word range (w_1, w_2) into tokens of equation matter. Word boundaries divide tokens, but so do operators like `+`, and boundaries can also occur in runs of alphanumerics if we spot symbol names: thus `mv^21` will be divided into tokens `m`, `v`, `^`, `21`.

The following routine sends each token in turn to the shift/reduce parser below, encoding each token as an enode. We return `NULL` if a problem message has to be issued, or else a pointer to the parsed tree if we succeed.

define `MAX_ENODES_IN_EXPRESSION 100`

```
equation_node *eqn_parse(equation *eqn) {
    int w1 = eqn->word_ref1, w2 = eqn->word_ref2;
LOG("Parsing equation %d <$W>\n", eqn->allocation_id, w1, w2);
    enode_sr_start();                                          start the shift-reduce parser
    equation_node *previous_token = NULL;
    int enode_count = 0;                                       number of tokens shipped so far
    int bl = 0;                                                bracket nesting level
    int wn = w1, i = 0; char *p = NULL;
```

```
    while ((wn <= w2) || (p)) {
        if (p == NULL) { i = 0; p = lw_array[wn++].lw_rawtext; }
        we are now at character i in string p, while wn is the next word
        equation_node *token = NULL;
        ⟨Break off a token from the current position 21⟩;
        ⟨Issue the token to the shift-reduce parser 25⟩;
        previous_token = token;
        if (p[i] == 0) p = NULL;
    }
    if (enode_sr_token(eqn, enode_new(END_EQN)) == FALSE)
        ⟨Equation fails in the shift-reduce parser 26⟩;
    equation_node *result = enode_sr_result();
    if (bl != 0) {
        equation_problem(_P_(C10EquationBracketMismatch), eqn, "",
            "this seems to use brackets in a mismatched way, since there "
            "are different numbers of left and right brackets '(' and ')'.");
        return NULL;
    }
    log_equation_node(result);
    return result;
}
```

§**21.** Note that symbol names can't begin with a digit.

⟨Break off a token from the current position 21⟩ ≡

```
    unsigned int c = p[i];
    if (isalpha(c)) ⟨Break off a symbol name as a token 22⟩
    else if (isdigit(c)) ⟨Break off a numeric constant as a token 23⟩
    else ⟨Break off an operator or a piece of punctuation as a token 24⟩;
```

This code is used in §20.

§**22.** Note that symbols are identified by recognition: without knowing the identities of the symbols, the syntax alone wouldn't tell us how to break them. We can only break `mc^2` as `m` followed by `c^2` if we know that `m` and `c` are symbols, rather than `mc`. (This is one reason why most programming languages don't allow implicit multiplication.)

⟨Break off a symbol name as a token 22⟩ ≡

```
    char text_of_symbol[16];
    int j;                                   the length of the symbol name we try to break off
    for (j=1; (j<15) && (isalnum(p[i+j-1])) && (token == NULL); j++) {
        copy the first j characters into a C string:
        int k; for (k=0; k<j; k++) text_of_symbol[k] = p[i+k];
        text_of_symbol[j] = 0;
        try to identify this as one of the declared symbols:
        equation_symbol *ev;
        for (ev = eqn->symbol_list; ev; ev = ev->next)
            if (strcmp(text_of_symbol, ev->variable_name) == 0) {
                token = enode_new_symbol(ev);
                i += j;
                break;
            }
    }
```

```
if (token == NULL) {
    equation_problem(_P_(C10EquationTokenUnrecognised), eqn, text_of_symbol,
        "the symbol '%3' is one that I don't recognise. It doesn't "
        "seem to be declared after the equation - for instance, "
        "by adding 'where %3 is a number'.");
    return NULL;
}
```

This code is used in §21.

§**23.** The following is reliable because a string of digits not starting with a 0 is always a valid number to Inform unless it overflows the virtual machine's capacity; and so is the number 0 itself.

⟨Break off a numeric constant as a token 23⟩ ≡

```
int j;                                    again the length of the number we try to break off
if ((p[i] == '0') && (isdigit(p[i+1]))) {
    equation_problem(_P_(C10EquationLeadingZero), eqn, "",
        "a number in an equation isn't allowed to begin with a "
        "'0' digit, so an equation like 'M = 007+Q' is against the rules.");
    return NULL;
}
copy the digits into a C string, flanked by spaces:
char text_of_number[16];
text_of_number[0] = ' ';
for (j=1; (j<14) && (isdigit(p[i])); j++) text_of_number[j] = p[i++];
text_of_number[j++] = ' ';
text_of_number[j] = 0;
now sneakily add this to the word stream, and let the S-parser read it:
feed_into_lexer(text_of_number, FALSE, FALSE);
specification *spec =
    parse_expression(lexer_wordcount-1, lexer_wordcount-1, TYPE_EXPCON);
this can only go wrong if there was an overflow, and a problem will have been issued for that:
if (spec_is_actual_CONSTANT(spec) == FALSE) return NULL;
token = enode_new_constant(spec);
```

This code is used in §21.

§**24.** Which leaves just the easiest case:

⟨Break off an operator or a piece of punctuation as a token 24⟩ ≡

```
switch (c) {
    case '=': token = enode_new_op(EQUALS_OPERATION); break;
    case '+': token = enode_new_op(PLUS_OPERATION); break;
    case '-':
        if ((previous_token == NULL) ||
            (previous_token->eqn_type == OPERATION_EQN) ||
            (previous_token->eqn_type == OPEN_BRACKET_EQN))
            token = enode_new_op(UNARY_MINUS_OPERATION);
        else
            token = enode_new_op(MINUS_OPERATION); break;
    case '/': token = enode_new_op(DIVIDE_OPERATION); break;
    case '*': token = enode_new_op(TIMES_OPERATION); break;
    case '^': token = enode_new_op(POWER_OPERATION); break;
    case '(': token = enode_new(OPEN_BRACKET_EQN); bl++; break;
```

```
        case ')': token = enode_new(CLOSE_BRACKET_EQN); bl--; break;
        default: {
            char symbol[2]; symbol[0] = c; symbol[1] = 0;
            equation_problem(_P_(C10EquationOperatorUnrecognised), eqn, symbol,
                "the symbol '%3' is one that I don't recognise. I was "
                "expecting an arithmetic sign, '+', '-', '*','/', or '^', "
                "or else '=' or a bracket '(' or ')'.");
            LOG("Bad operator '%c'\n", c); return NULL;
        }
    }
    i++;
```

This code is used in §21.

§**25.** So now we have our next token, and are ready to ship it. But if we detect an implicit multiplication, for instance between `m` and `c^2` in `E=mc^2`, we issue that as an `IMPLICIT_TIMES_OPERATION` enode in between.

⟨Issue the token to the shift-reduce parser 25⟩ ≡

```
    if (multiplication_is_implied(previous_token, token)) {
        if (enode_sr_token(eqn, enode_new_op(IMPLICIT_TIMES_OPERATION)) == FALSE)
            ⟨Equation fails in the shift-reduce parser 26⟩;
        enode_count++;
    }
    if (enode_sr_token(eqn, token) == FALSE)
        ⟨Equation fails in the shift-reduce parser 26⟩;
    enode_count++;
    if (enode_count >= MAX_ENODES_IN_EXPRESSION - 2) {
        equation_problem(_P_(C10EquationTooComplex), eqn, "",
            "this is too long and complex an equation.");
        return NULL;
    }
```

This code is used in §20.

§**26.** In case any of the enode insertions fail. It's tricky to generate good error messages and recover well when an operator-precedence grammar fails to match in a parser like this, so we'll fall back on this:

⟨Equation fails in the shift-reduce parser 26⟩ ≡

```
    equation_problem(_P_(C10EquationMispunctuated), eqn, "",
        "this seems to be wrongly punctuated, and doesn't make sense as a "
        "mathematical formula.");
    return NULL;
```

This code is used in §20,25,20,25,20,25.

§**27.** Lastly, here is when multiplication is implied:

```
int multiplication_is_implied(equation_node *previous_token, equation_node *token) {
    int lt, rt;
    if ((token == NULL) || (previous_token == NULL)) return FALSE;
    lt = previous_token->eqn_type; rt = token->eqn_type;
    if (((lt == SYMBOL_EQN) || (lt == CONSTANT_EQN) || (lt == CLOSE_BRACKET_EQN)) &&
        ((rt == SYMBOL_EQN) || (rt == CONSTANT_EQN) || (rt == OPEN_BRACKET_EQN)))
        return TRUE;
    return FALSE;
}
```

§**28. The shift-reduce parser.** This is a classic algorithm for expression-evaluator grammars; see for instance Aho, Sethi and Ullman, *Compilers*, §4.6 in the second edition. We use a pair of stacks. The SR stack holds possible attempts to understand what we have so far, given the tokens that have arrived; the emitter stack holds nodes which form pieces of the output tree as it is assembled. Nodes flow from our input, are usually "shifted" onto the SR stack for a while, are eventually "reduced" in clumps taken off this stack and "emitted", then go onto the emitter stack, and are finally removed as they are made into trees.

The flow is therefore always forwards; tokens can't slosh back and forth between the stacks. On each iteration, at least one token makes progress, so if there are N tokens of input (including both end marker tokens) then we take at worst $2N$ steps to finish. Each stack can't need more than N entries, and N is bounded above by `MAX_ENODES_IN_EXPRESSION` plus 2 (allowing for the end markers). So:

```
int SR_sp = 0;
equation_node *SR_stack[MAX_ENODES_IN_EXPRESSION+2];
int emitter_sp = 0;
equation_node *emitter_stack[MAX_ENODES_IN_EXPRESSION+2];
void log_sr_stacks(void) {
    int i;
    LOG("SR: ");
    for (i=0; i<SR_sp; i++) { LOG(" %d: ", i); log_equation_node(SR_stack[i]); }
    LOG("EMITTER: ");
    for (i=0; i<emitter_sp; i++) { LOG(" %d: ", i); log_equation_node(emitter_stack[i]); }
}
```

§**29.** The start and finish are as follows. At the start, the emitter stack is empty and the SR stack contains an `END_EQN` token, which represents the left-hand end of the expression. (Another such token, this time representing the right-hand end, will be sent by the routines above at the end of the stream. So there will be two `END_EQN` tokens in play.)

```
void enode_sr_start(void) {
    SR_stack[0] = enode_new(END_EQN);
    SR_sp = 1;
    emitter_sp = 0;
}
```

§**30.** If we have succeeded, the end state of the emitter stack contains a single node: the head of the tree we have grown to represent the expression.

```
equation_node *enode_sr_result(void) {
    return emitter_stack[0];
}
```

§**31.** So the following is the routine which iteratively deals with tokens as they arrive. As noted above, the loop however ominous always terminates.

For proofs and explanations see ASU, but the idea is simple enough: as we see the expression a little at a time, we collect possibilities of how to read it on the SR-stack, until we reach a point where it's possible to tell what was meant; we then reduce the SR-stack by taking the winning possibility off the top and moving it to the emitter stack. For instance, if we have read `4 + 5` then we don't know yet whether the `+` will add the 4 to the 5; if the next token is `+` or `END_EQN` then it will, but if the next token is `*` then it won't, because we're looking at something like `4 + 5 * 6`.

If the next token is of lower precedence than `+` then we "reduce" – telling the emitter about the addition, which we now understand – but if it's higher, as with `*`, then we "shift", meaning, we postpone worrying about the addition and start worrying about the multiplication instead; our new problem, working out what `*` applies to, sits on top of the addition problem on the SR-stack.

```
int enode_sr_token(equation *eqn, equation_node *tok) {
    int safety_cutout = 3*MAX_ENODES_IN_EXPRESSION;
    while (TRUE) {
        if (SR_sp <= 0) internal_error("SR stack empty");
        if ((SR_stack[SR_sp-1]->eqn_type == END_EQN) && (tok->eqn_type == END_EQN)) break;
        if ((enode_lt(SR_stack[SR_sp-1], tok)) || (enode_eq(SR_stack[SR_sp-1], tok)))
            ⟨Shift an enode onto the SR-stack 32⟩
        else if (enode_gt(SR_stack[SR_sp-1], tok))
            ⟨Reduce some enodes from the SR-stack to the emitter stack 33⟩
        else return FALSE;
        if (safety_cutout-- < 0) internal_error("SR parser deadlocked");
    }
    if ((emitter_sp != 1) || (SR_sp != 1)) return FALSE;
    return TRUE;
}
```

§**32.** After shifting, we return a signal of success, which asks for the next token to be sent.

⟨Shift an enode onto the SR-stack 32⟩ ≡

```
    SR_stack[SR_sp++] = tok;
    return TRUE;
```

This code is used in §31.

§**33.** The ASU book is a little vague about what happens if there is an underflow here, I think because it's possible to set up the grammar such that an underflow cannot occur. But I can see no obvious proof that it will never occur for us given syntactically incorrect input, so we will return `FALSE` on an underflow to be safe.

Note that we can never emit the bottom-most token on the SR stack: that's the left-hand end marker, so can never be validly part of any arithmetic. So an underflow occurs if that's all that's left, i.e., when the SR stack pointer is 1, not 0.

⟨Reduce some enodes from the SR-stack to the emitter stack 33⟩ ≡

```
do { if (SR_sp <= 1) return FALSE;
     if (enode_emit(SR_stack[--SR_sp]) == FALSE) return FALSE;
} while ((SR_sp >= 1) && (enode_lt(SR_stack[SR_sp-1], SR_stack[SR_sp]) == FALSE));
```

This code is used in §31.

§**34.** The key point is that if nodes arrive at the SR parser in their ordinary order of mathematical writing, then they "reduce" off the SR stack and onto the emitter stack in reverse Polish notation order. Thus the sequence `4 + 2 * 7` is emitted as `4 2 7 * +`. RPN has no need of brackets to clarify the sequence of operation, and it's very easy to build a tree from.

```
int enode_emit(equation_node *tok) {
    switch (tok->eqn_type) {
        case SYMBOL_EQN: case CONSTANT_EQN:
            emitter_stack[emitter_sp++] = tok;
            break;
        case OPERATION_EQN:
            if (tok->eqn_operation == IMPLICIT_TIMES_OPERATION)
                tok->eqn_operation = TIMES_OPERATION;
            if (arithmetic_op_is_unary(tok->eqn_operation)) tok->enode_arity = 1;
            else tok->enode_arity = 2;
            int i;
            for (i = tok->enode_arity - 1; i >= 0; i--) {
                emitter_sp--;
                if (emitter_sp < 0) return FALSE;
                tok->enode_operands[i] = emitter_stack[emitter_sp];
            }
            emitter_stack[emitter_sp++] = tok;
            break;
    }
    return TRUE;
}
```

§**35.** All we need now is to decide the order of precedence of our tokens, though this isn't as simple as it looks, because they are not all symmetrical left-right. That's obviously true of things like an open bracket `(`, which affects the stuff to the left very differently from the stuff to the right. But it is also true of operators. `+` may be associative mathematically, but in computing there's a difference between evaluating `a + (b+c)` and `(a+b) + c`.

All of this means there's no simple order relationship on the tokens, where $T < S$ if and only if $S > T$. We order them using a numerical score, but they get one score $f(T)$ if they appear on the left and another score $g(T)$ if they appear on the right:

```
int enode_lt(equation_node *tok1, equation_node *tok2) {
    int f_left = f_function(tok1), g_right = g_function(tok2);
    if (f_left < g_right) return TRUE; return FALSE;
}
int enode_eq(equation_node *tok1, equation_node *tok2) {
    int f_left = f_function(tok1), g_right = g_function(tok2);
    if (f_left == g_right) return TRUE; return FALSE;
}
int enode_gt(equation_node *tok1, equation_node *tok2) {
    int f_left = f_function(tok1), g_right = g_function(tok2);
    if (f_left > g_right) return TRUE; return FALSE;
}
```

§**36.** And here are those scorings. Note that for the binary operators, f scores are always slightly higher than g scores: that's what makes them left associative, that is, $a+b+c$ is read as $(a+b)+c$. The exception to this is raising to powers: `a^2^3` evaluates a^8, not a^6, because it is read as `a^(2^3)`.

Implicit multiplication has higher precedence than explicit. This is actually to give it higher precedence than division (which has to have the same precedence as explicit multiplication), and is so that `ab/cd` evaluates $(ab)/(cd)$ rather than $a \cdot (b/c) \cdot d$.

```
int f_function(equation_node *tok) {
    switch (tok->eqn_type) {
        case SYMBOL_EQN: case CONSTANT_EQN: return 14;
        case OPERATION_EQN:
            switch (tok->eqn_operation) {
                case EQUALS_OPERATION: return 2;
                case PLUS_OPERATION: case MINUS_OPERATION: return 4;
                case TIMES_OPERATION: case DIVIDE_OPERATION: return 6;
                case IMPLICIT_TIMES_OPERATION: return 8;
                case POWER_OPERATION: return 9;
                case UNARY_MINUS_OPERATION: return 1;
            }
            internal_error("unknown operator precedence");
        case OPEN_BRACKET_EQN: return 0;
        case CLOSE_BRACKET_EQN: return 14;
        case END_EQN: return 0;
    }
    internal_error("unknown f-value"); return 0;
}
```

§**37.** And symmetrically:

```
int g_function(equation_node *tok) {
    switch (tok->eqn_type) {
        case SYMBOL_EQN: case CONSTANT_EQN: return 13;
        case OPERATION_EQN:
            if (tok) switch (tok->eqn_operation) {
                case EQUALS_OPERATION: return 1;
                case PLUS_OPERATION: case MINUS_OPERATION: return 3;
                case TIMES_OPERATION: case DIVIDE_OPERATION: return 5;
                case IMPLICIT_TIMES_OPERATION: return 7;
                case POWER_OPERATION: return 10;
                case UNARY_MINUS_OPERATION: return 12;
            }
            internal_error("unknown operator precedence");
        case OPEN_BRACKET_EQN: return 13;
        case CLOSE_BRACKET_EQN: return 0;
        case END_EQN: return 0;
    }
    internal_error("unknown g-value"); return 0;
}
```

§**38. Typechecking equations.** The SR parser can generate trees for any syntactically valid equation, but it may be something using = inappropriately or not at all. We rule that out first: we want the top node in the tree to be the unique = operator.

```
int eqn_typecheck(equation *eqn) {
    switch (enode_count_equals(eqn->parsed_equation)) {
        case 0:
            equation_problem(_P_(C10EquationDoesntEquate), eqn, "",
                "this equation doesn't seem to contain an equals sign, and "
                "without '=' there is no equating anything with anything.");
            return FALSE;
        case 1:
            if (enode_is_equals(eqn->parsed_equation) == FALSE) {
                equation_problem(_P_(C10EquationEquatesBadly), eqn, "",
                    "the equals sign '=' here seems to be buried inside the "
                    "formula, not at the surface. For instance, 'F = ma' is "
                    "fine, but 'F(m=a)' would not make sense - the '=' would "
                    "be inside brackets.");
                return FALSE;
            }
            break;
        default:
            equation_problem(_P_(C10EquationEquatesMultiply), eqn, "",
                "this equation seems to contain more than one equals "
                "sign '='.");
            return FALSE;
    }
    return enode_typecheck(eqn, eqn->parsed_equation);
}
```

§**39.** A recursive count of instances down the tree from `tok`:

```
int enode_count_equals(equation_node *tok) {
    int c = 0, i;
    if (tok) {
        if (enode_is_equals(tok)) c++;
        for (i=0; i<tok->enode_arity; i++)
            c += enode_count_equals(tok->enode_operands[i]);
    }
    return c;
}
int enode_is_equals(equation_node *tok) {
    if (tok == NULL) return FALSE;
    if ((tok->eqn_type == OPERATION_EQN) && (tok->eqn_operation == EQUALS_OPERATION))
        return TRUE;
    return FALSE;
}
```

§**40.** Now we come to the real typechecking. The following is called, depth-first, at each node in the equation; it has to assign a KOV at every node, in such a way that all operations are dimensionally valid. We return `FALSE` if we are obliged to issue a problem message.

```
int enode_typecheck(equation *eqn, equation_node *tok) {
    int result = TRUE;
    if (tok == NULL) return result;
    int i;
    for (i=0; i<tok->enode_arity; i++)
        if (enode_typecheck(eqn, tok->enode_operands[i]) == FALSE)
            result = FALSE;
    if (result)
        switch (tok->eqn_type) {
            case SYMBOL_EQN: tok->enode_kov = tok->leaf_symbol->var_kov; break;
            case CONSTANT_EQN: tok->enode_kov = spec_get_kind_of_value(tok->leaf_constant);
break;
            case OPERATION_EQN:
                if (tok->eqn_operation == EQUALS_OPERATION)
                    ⟨Typecheck the set-equals node at the top level 41⟩
                else if (tok->eqn_operation == POWER_OPERATION)
                    ⟨Typecheck a raise-to-integer-power node 42⟩
                else
                    ⟨Typecheck a general operation node 44⟩;
                break;
            default: internal_error("forbidden enode found in parsed equation");
        }
    return result;
}
```

§**41.** We are in the realm of quasinumerical KOVs here, so there's no possible fuss about implicit casting. (But if we ever add a floating-point number KOV to Inform, we'll have to worry about writing an integer to a float here.)

⟨Typecheck the set-equals node at the top level 41⟩ ≡

```
if (kov_compare(tok->enode_operands[0]->enode_kov,
    tok->enode_operands[1]->enode_kov) == FALSE) {
    result = FALSE;
    equation_problem(_P_(C10EquationIncomparable), eqn, "",
        "this equation tries to set two values equal which have "
        "different kinds from each other.");
}
tok->enode_kov = tok->enode_operands[0]->enode_kov;
```

This code is used in §40.

§**42.** The restriction on powers is needed to make it possible to know the dimensions of the result. If h is a length, h^2 is an area but h^3 is a volume; so if all we have is h^n, and we don't know the value of n, we're unable to see what equations h^n can appear in.

⟨Typecheck a raise-to-integer-power node 42⟩ ≡

```
equation_node *base = tok->enode_operands[0];
equation_node *power = tok->enode_operands[1];
if (kov_is_dimensionless(base->enode_kov)) {
    if ((is_kova(power->enode_kov, NUMBER_TY) == FALSE) ||
        (power->eqn_type != CONSTANT_EQN)) {
        result = FALSE;
        equation_problem(_P_(C10EquationNonIntPower), eqn, "",
            "the '^' raise-to-power symbol can only be used to raise to a "
            "constant positive integer. So 'mv^2' is fine, but not 'k^F' "
            "for a force 'F'.");
    }
    tok->enode_kov = base->enode_kov;
} else if ((is_kova(power->enode_kov, NUMBER_TY) == FALSE) ||
    (power->eqn_type != CONSTANT_EQN)) {
    result = FALSE;
    equation_problem(_P_(C10EquationDimensionPower), eqn, "",
        "the '^' raise-to-power symbol can only be used to raise a value "
        "with dimensions to a specific number. So 'mv^2' is fine, but not "
        "'mv^n' or 'mv^(1+n)'. (This is because I would need to work out what "
        "kind of value 'v^n' would be, and the answer would depend on 'n', "
        "but I wouldn't know what 'n' is.)");
} else ⟨Take the dimensional power of the KOV of the base 43⟩;
```

This code is used in §40.

§**43.** To work out the KOV of b^n, we use repeated multiplication or division of dimensions; if $n = 0$ then we have a dimensionless value, and choose `NUMBER_TY` as the simplest possibility.

⟨Take the dimensional power of the KOV of the base 43⟩ ≡
```
kind_of_value *kov = kova(NUMBER_TY);
int op = TIMES_OPERATION;
int n = value_of_NUMBER_type(power->leaf_constant);
if (n < 0) { n = -n; op = DIVIDE_OPERATION; }
while (n > 0) {
    kov = arithmetic_on_kovs(kov, base->enode_kov, op);
    n--;
}
tok->enode_kov = kov;
```

This code is used in §42.

§**44.** The following is easy because it was the content of the whole "Dimensions.w" section:

⟨Typecheck a general operation node 44⟩ ≡
```
if (arithmetic_op_is_unary(tok->eqn_operation))
    tok->enode_kov = arithmetic_on_kovs(
        tok->enode_operands[0]->enode_kov, NULL, tok->eqn_operation);
else
    tok->enode_kov = arithmetic_on_kovs(
        tok->enode_operands[0]->enode_kov, tok->enode_operands[1]->enode_kov,
        tok->eqn_operation);
if (tok->enode_kov == NULL) {
    result = FALSE;
    LOG("Failed at operation:\n"); log_equation_node(tok);
    if (arithmetic_op_is_unary(tok->eqn_operation))
        ⟨Issue unary equation typechecking problem message 45⟩
    else
        ⟨Issue binary equation typechecking problem message 46⟩;
}
```

This code is used in §40.

§**45.** These unary operations all typecheck, at present, because they come into being only by rearranging other operations which have already typechecked; that would stop being true if we added notations for root and cube root.

⟨Issue unary equation typechecking problem message 45⟩ ≡
```
quote_source(1, current_sentence);
specification *spec1 = new_generic_CONSTANT_type(tok->enode_operands[0]->enode_kov);
quote_spec(4, spec1);
switch(i) {
    case UNARY_MINUS_OPERATION:
        quote_text(6, "negating");
        break;
    case ROOT_OPERATION:
        quote_text(6, "taking the square root of");
        break;
    case CUBEROOT_OPERATION:
        quote_text(6, "taking the cube root of");
        break;
```

```
    }
    handmade_problem(_P_(BelievedImpossible));
    issue_problem_segment(
        "You wrote %1, but that equation seems to involve %6 %4, which is not "
        "good arithmetic.");
    issue_problem_end();
```

This code is used in §44.

§**46.**

⟨Issue binary equation typechecking problem message 46⟩ ≡

```
    quote_source(1, current_sentence);
    specification *spec1 = new_generic_CONSTANT_type(tok->enode_operands[0]->enode_kov);
    specification *spec2 = new_generic_CONSTANT_type(tok->enode_operands[1]->enode_kov);
    quote_spec(4, spec1);
    quote_spec(5, spec2);
    switch(i) {
        case PLUS_OPERATION:
            quote_text(6, "adding"); quote_text(7, "to");
            break;
        case MINUS_OPERATION:
            quote_text(6, "subtracting"); quote_text(7, "from");
            break;
        case TIMES_OPERATION:
            quote_text(6, "multiplying"); quote_text(7, "by");
            break;
        case DIVIDE_OPERATION:
        case REMAINDER_OPERATION:
            quote_text(6, "dividing"); quote_text(7, "by");
            break;
        case POWER_OPERATION:
            quote_text(6, "raising"); quote_text(7, "the the power of");
            break;
    }
    handmade_problem(_P_(C10EquationBadArithmetic));
    issue_problem_segment(
        "You wrote %1, but that equation seems to involve "
        "%6 %4 %7 %5, which is not good arithmetic.");
    issue_problem_end();
```

This code is used in §44.

§**47. Compiling.** We want each equation to have a distinct value at runtime. The following routines do nothing (for now, anyway) except to give the I6 identifiers for equations a value; they are never called.

```
void compile_equations(OUTPUT_STREAM) {
    equation *eqn;
    LOOP_OVER(eqn, equation) {
        WRITE("[ %s;\n", eqn->eqn_I6_identifier); INDENT;
        WRITE("return 0;\n");
        OUTDENT; WRITE("];\n");
    }
}
```

The function compile_equations is invoked by a command in a `.i6t` template file.

§**48.** These identifiers are used to compile equation names as values, so:

```
char *eqn_get_I6_representation(equation *eqn) {
    return eqn->eqn_I6_identifier;
}
```

The function eqn_get_I6_representation is called from 7/vasp.

§**49. Solving.** So we can finally turn to putting equations to use. Firstly, when a named equation is used, a "where..." clause is sometimes given to make temporary assignments (see above); what happens is that the S-parser temporarily sets the usage words of the equation to the relevant text...

```
void eqn_set_usage_notes(equation *eqn, int u1, int u2) {
    eqn->usage_w1 = u1; eqn->usage_w2 = u2;
}
```

The function eqn_set_usage_notes is called from 5/mlc.

§**50.** ...so that, when we come to solve the equation (i.e., later on in the invocation compiler), we know where to find these temporary assignments. They are wiped out once this compilation is over.

```
void compile_solution(OUTPUT_STREAM, int w1, int w2, equation *eqn) {
    if (eqn->usage_w1 >= 0)
        eqn_declare_variables_inner(eqn, eqn->usage_w1, eqn->usage_w2, TRUE);
    compile_solution_inner(OUT, w1, w2, eqn);
    eqn_remove_temp_variables(eqn);
    eqn->usage_w1 = -1; eqn->usage_w2 = -1;
}
```

The function compile_solution is called from 12/cinv.

§**51.** With that dance out of the way, we can concentrate on the actual task. We have to compile code which assigns the correct value to the symbol specified by (w_1, w_2), according to the equation `eqn`.

```
void compile_solution_inner(OUTPUT_STREAM, int w1, int w2, equation *eqn) {
    equation_symbol *to_solve = NULL;
    ⟨Identify which symbol in the equation we are solving for 52⟩;
    ⟨Rearrange the equation so that this symbol is the entire LHS 53⟩;
    ⟨Identify the symbols in the equation with local variables 54⟩;
    WRITE("! Solving %s for '%s'\n", eqn->eqn_I6_identifier, to_solve->variable_name);
    enode_compile(OUT, eqn->parsed_equation);
}
```

§**52.** Note the case sensitivity here.

⟨Identify which symbol in the equation we are solving for 52⟩ ≡

```
    if (w1 == w2) {
        char *p = lw_array[w1].lw_rawtext;
        equation_symbol *ev;
        for (ev = eqn->symbol_list; ev; ev = ev->next)
            if (strcmp(p, ev->variable_name) == 0)
                to_solve = ev;
    }
    if (to_solve == NULL) {
        quote_source(1, current_sentence);
        quote_words(2, w1, w2);
        quote_words(3, eqn->word_ref1, eqn->word_ref2);
        handmade_problem(_P_(C10EquationBadTarget));
        issue_problem_segment(
            "In %1, you asked to let %2 be given by the equation '%3', "
            "but '%2' isn't a symbol in that equation.");
        issue_problem_end();
        return;
    }
```

This code is used in §51.

§**53.** This step is not easy, but is delegated to `eqn_rearrange` below, so it looks easy here. The surprising thing is the fresh round of typechecking: why do we do that? The answer is not that we doubt whether the equation is still valid – the rearranged equation should pass if and only if the original did, if we've implemented all of this correctly – but because the alterations made to the tree mean that the assignments of KOVs at each node are now potentially incorrect. Re-typechecking will recalculate these.

⟨Rearrange the equation so that this symbol is the entire LHS 53⟩ ≡

```
if (eqn_rearrange(eqn, to_solve) == FALSE) {
    quote_source(1, current_sentence);
    quote_words(2, w1, w2);
    quote_words(3, eqn->word_ref1, eqn->word_ref2);
    handmade_problem(_P_(C10EquationInsoluble));
    issue_problem_segment(
        "In %1, you asked to let %2 be given by the equation '%3', "
        "but I am unable to rearrange the equation in any simple way "
        "so that it sets '%2' equal to something else. Maybe you could "
        "write a more explicit equation? (You're certainly better at "
        "maths than I am; I can only make easy deductions.)");
    issue_problem_end();
    return;
}
if (eqn_typecheck(eqn) == FALSE) return;
LOG("Rearranged equation reads:\n"); log_equation_node(eqn->parsed_equation);
```

This code is used in §51.

§**54.** Suppose we read a phrase such as

let PE be given by PE = mgh, where g = 9.801 m/ss;

We can only compile code to do this if we can identify values for the symbols. "g" is not a problem because a temporary assignment supplies this. For each symbol `ev` which isn't a constant, we must set `ev->local_map` to the number of a local variable, or else issue a problem message.

⟨Identify the symbols in the equation with local variables 54⟩ ≡

```
equation_symbol *ev;
for (ev = eqn->symbol_list; ev; ev = ev->next)
    if (ev->var_const == NULL) {
        ev->local_map = parse_name_local_to_current_stack_frame(
            ev->variable_wn, ev->variable_wn);
        if (ev->local_map < 0)
            ⟨Can't find an unset symbol among the local variables 55⟩
        else
            ⟨Check that the KOV of the local variable matches that of the symbol 56⟩;
    }
```

This code is used in §51.

§**55.** In the above example, finding "PE" should not be a problem: this is the `to_solve` symbol, and it must be a current local variable name since the "let" will have created it as such if it didn't already exist. But things can certainly go wrong with "m" and "h", which need to exist as local variables in the current stack frame.

⟨Can't find an unset symbol among the local variables 55⟩ ≡

```
if (ev == to_solve) internal_error("can't find 'let' variable to assign");
quote_source(1, current_sentence);
quote_words(2, w1, w2);
quote_words(3, eqn->word_ref1, eqn->word_ref2);
quote_words(4, ev->variable_wn, ev->variable_wn);
handmade_problem(_P_(C10EquationSymbolMissing));
issue_problem_segment(
    "In %1, you asked to let %2 be given by the equation '%3', "
    "but I can't see what to use for '%4'. The usual idea is "
    "to set the other variables in the equation using 'let': "
    "so adding 'let %4 be ...' before trying to find '%2' "
    "should work.");
issue_problem_end();
return;
```

This code is used in §54.

§**56.** In the case of the symbol we are setting, the local variable might be one which has only just been created and thus has no value yet – not having set it, Inform hasn't given it a kind of value more explicit than `ANY_VALUE_TY`. We can improve that by giving it the KOV of the symbol it is to match.

In all other cases, the local variable already exists and has a fixed KOV. This must exactly match that of the symbol. (Again, if we ever need implicit casting between quasinumerical KOVs, we'll have to return to this.)

⟨Check that the KOV of the local variable matches that of the symbol 56⟩ ≡

```
kind_of_value *kov = kov_of_local(ev->local_map);
if (is_kova(kov, ANY_VALUE_TY)) {
    kov = ev->var_kov;
    set_KOV_of_local_variable(ev->local_map, kov);
}
if (kov_compare(kov, ev->var_kov) == FALSE) {
    quote_source(1, current_sentence);
    quote_words(2, w1, w2);
    quote_words(3, eqn->word_ref1, eqn->word_ref2);
    quote_words(4, ev->variable_wn, ev->variable_wn);
    quote_kov(5, kov);
    quote_kov(6, ev->var_kov);
    handmade_problem(_P_(C10EquationSymbolWrongKOV));
    issue_problem_segment(
        "In %1, you asked to let %2 be given by the equation '%3', "
        "but in that equation '%4' is supposedly %6 - whereas right "
        "here, it seems to be %5. Perhaps two different quantities have "
        "ended up with the same symbol in the source text?");
    issue_problem_end();
    return;
}
```

This code is used in §54.

§**57.** Actual compilation is simple, since the tree is set up for it.

```
void enode_compile(OUTPUT_STREAM, equation_node *tok) {
    switch (tok->eqn_type) {
        case SYMBOL_EQN:
            if (tok->leaf_symbol->var_const)
                spec_compile(OUT, tok->leaf_symbol->var_const);
            else
                WRITE("t_%d", tok->leaf_symbol->local_map); break;
        case CONSTANT_EQN: spec_compile(OUT, tok->leaf_constant); break;
        case OPERATION_EQN: WRITE("("); ⟨Compile a single operation 58⟩; WRITE(")"); break;
        default: internal_error("forbidden enode found in parsed equation");
    }
}
```

§**58.** And here we handle operation nodes:

⟨Compile a single operation 58⟩ ≡

```
    equation_node *left = tok->enode_operands[0];
    equation_node *right = tok->enode_operands[1];
    switch (tok->eqn_operation) {
        case POWER_OPERATION:
            ⟨Compile a power of the left operand 59⟩; break;
        case EQUALS_OPERATION:
            enode_compile(OUT, left); WRITE(" = "); enode_compile(OUT, right); break;
        case PLUS_OPERATION:
            enode_compile(OUT, left); WRITE(" + "); enode_compile(OUT, right); break;
        case MINUS_OPERATION:
            enode_compile(OUT, left); WRITE(" - "); enode_compile(OUT, right); break;
        case TIMES_OPERATION:
            enode_compile(OUT, left); WRITE(" * "); enode_compile(OUT, right);
            kov_rescale_multiplication(OUT, left->enode_kov, right->enode_kov);
            break;
        case DIVIDE_OPERATION:
            WRITE("IntegerDivide("); enode_compile(OUT, left);
            kov_rescale_division(OUT, left->enode_kov, right->enode_kov);
            WRITE(", "); enode_compile(OUT, right); WRITE(")");
            break;
        case UNARY_MINUS_OPERATION:
            WRITE("-("); enode_compile(OUT, left); WRITE(")");
            break;
        case ROOT_OPERATION:
            WRITE("SquareRoot("); enode_compile(OUT, left);
            kov_rescale_root(OUT, left->enode_kov, 2); WRITE(")");
            break;
        case CUBEROOT_OPERATION:
            WRITE("CubeRoot("); enode_compile(OUT, left);
            kov_rescale_root(OUT, left->enode_kov, 3); WRITE(")");
            break;
        default: internal_error("unimplemented operation");
    }
```

This code is used in §57.

§**59.** We accomplish powers by repeated multiplication. This is partly because I6 has no "to the power of" function, partly because the powers involved will always be small, partly because of the need for scaling to come out right.

⟨Compile a power of the left operand 59⟩ ≡

```
int p = value_of_NUMBER_type(right->leaf_constant);
if (p < 0) internal_error("can't compile negative powers yet");
if (p > 0) enode_compile(OUT, left);
while (p > 1) {
    WRITE(" * "); enode_compile(OUT, left);
    kov_rescale_multiplication(OUT, left->enode_kov, left->enode_kov);
    p--;
}
```

This code is used in §58.

§**60. Rearrangement.** We carry out only the simplest of operations, but it's surprising how often that's good enough: if it isn't, we simply return `FALSE`.

Everything we do will be reversible, which is important since we are changing the `parsed_equation` tree, and we don't want to be changing our view of what the equation means in the process. One thing that never changes is that the top node of the equation is always the unique "equal to" node in the tree.

Suppose we are solving for `v`, which occurs in just one place in the equation. Either it's at the top level under the `=`, in which case we now have an explicit formula for `v`, or it's stuck underneath some operation node. We rearrange the tree to move this operation over to the other side, which allows `v` to make progress – see below for a proof that this terminates.

```
int eqn_rearrange(equation *eqn, equation_symbol *to_solve) {
    while (TRUE) {
        ⟨Swap the two sides if necessary so that v occurs only once and on the left 61⟩;
        equation_node *old_LHS = eqn->parsed_equation->enode_operands[0];
        equation_node *old_RHS = eqn->parsed_equation->enode_operands[1];
        if (old_LHS->eqn_type != OPERATION_EQN) break;
        if (old_LHS->enode_arity == 2)
            ⟨Rearrange to move v upwards through this binary operator 63⟩
        else
            ⟨Rearrange to move v upwards through this unary operator 65⟩;
    }
    return TRUE;
}
```

§**61.** We have no ability to gather terms, so the variable `v` we are solving for can only occur once in the formula. In Inform's idea of equations, `A = B` and `B = A` have the same meaning, so we'll place `v` on the left.

⟨Swap the two sides if necessary so that v occurs only once and on the left 61⟩ ≡

```
int lc = enode_count_var(eqn->parsed_equation->enode_operands[0], to_solve);
int rc = enode_count_var(eqn->parsed_equation->enode_operands[1], to_solve);
if (lc + rc != 1) return FALSE;
if (lc == 0) {
    equation_node *swap = eqn->parsed_equation->enode_operands[0];
    eqn->parsed_equation->enode_operands[0] = eqn->parsed_equation->enode_operands[1];
    eqn->parsed_equation->enode_operands[1] = swap;
}
```

This code is used in §60.

§**62.** The main loop above terminates because on each iteration, either

(i) the tree depth of `v` below `=` decreases by 1, or
(ii) the tree depth of `v` remains the same but the number of `MINUS_OPERATION` or `DIVIDE_OPERATION` nodes in the tree decreases by 1.

Since at any given time there are a finite number of `MINUS_OPERATION` or `DIVIDE_OPERATION` nodes, case (ii) cannot repeat indefinitely, and we must therefore eventually fall into case (i); and then subsequently do so again, and so on; and so the tree depth of `v` will ultimately fall to 1, at which point it is at the top level as required and we break out of the loop.

§**63.** So the rearrangement moves have to make sure the "(i) or (ii)" property always holds. The simplest case to understand is `+`. Suppose we have:

```
=
    +
        V
        E
    R
```

representing $(V + E) = R$, where V is the sub-equation containing v. (E is an arbitrary sub-equation, and R is the right hand side.) One of the two operands of `+` will be "promoted", moving upwards in the tree, and since we can choose to promote either V or E, we'll choose V, thus obtaining:

```
=
    V
    -
        R
        E
```

that is, $V = (R - E)$. Since V has moved upwards, so has the unique instance of v, and therefore the tree depth of v has decreased by 1 – property (i). Multiplication is similar, but turns into division on the right hand side.

But now consider `-`. When we rearrange:

```
=
    -
        E
        V
    R
```

representing $(E - V) = R$ we no longer have a choice of which operand of `-` to promote: we have to promote the right operand, and that produces $E = (R + V)$. The tree depth of v is not improved,

and it's now over on the right hand side. The next iteration of the main loop will swap sides again so that we have $(R + V) = E$. But a tricky node (subtraction or division) has been exchanged out of the tree for an easy one (addition or multiplication), so we fail property (i) but achieve property (ii).

```
⟨Rearrange to move v upwards through this binary operator 63⟩ ≡
    rearrange to move this operator
    int op = old_LHS->eqn_operation;
    if (op == POWER_OPERATION)
        ⟨Rearrange to remove a power 64⟩
    else {
        int promote = 0, new_op = PLUS_OPERATION;
        if (enode_count_var(old_LHS->enode_operands[1], to_solve) > 0) promote = 1;
        switch (op) {
            case PLUS_OPERATION: new_op = MINUS_OPERATION; break;
            case MINUS_OPERATION: new_op = PLUS_OPERATION; promote = 0; break;
            case TIMES_OPERATION: new_op = DIVIDE_OPERATION; break;
            case DIVIDE_OPERATION: new_op = TIMES_OPERATION; promote = 0; break;
            default: LOG("%d\n", op); internal_error("strange operator in rearrangement");
        }
        equation_node *E = old_LHS->enode_operands[1 - promote];
        the new LHS is the promoted operand:
        eqn->parsed_equation->enode_operands[0] = old_LHS->enode_operands[promote];
        the new RHS is the operator which used to be the LHS...
        eqn->parsed_equation->enode_operands[1] = old_LHS;
        ...the former RHS being the operand replacing the promoted one...
        old_LHS->enode_operands[0] = old_RHS;
        old_LHS->enode_operands[1] = E;
        ...except that the operator reverses in "sense"
        old_LHS->eqn_operation = new_op;
    }
```

This code is used in §60.

§64. Solving $x^v = y$ for v requires logs, which are not in our scheme; and solving $v^n = y$ for non-constant n is no better. So in either case we surrender by returning `FALSE`.

In fact, the only cases we can solve at present are $V^2 = y$ and $V^3 = y$. It would be easy to add solutions for $V^4 = y$, $V^6 = y$ and in general for $V^k = y$ where the only prime factors of k are 2 and 3, but this is not something people are likely to need very much. The taking of 4th or higher roots hardly ever occurs in physical equations, and anyone wanting this will have to write more explicit source text.

Anyway, rearrangement for our easy cases is indeed easy:

```
=
    ^
        V
        2
    R
```

becomes

```
=
    V
    square-root
        R
```

and V is always promoted, so we achieve property (i); and similarly for cube roots.

⟨Rearrange to remove a power 64⟩ ≡

```
if (old_LHS->enode_operands[1]->eqn_type != CONSTANT_EQN) return FALSE;
int p = value_of_NUMBER_type(old_LHS->enode_operands[1]->leaf_constant);
int new_op = -1;
if (p == 2) new_op = ROOT_OPERATION;
if (p == 3) new_op = CUBEROOT_OPERATION;
if (new_op == -1) return FALSE;
eqn->parsed_equation->enode_operands[0] = old_LHS->enode_operands[0];
eqn->parsed_equation->enode_operands[1] = old_LHS;
old_LHS->eqn_operation = new_op;
old_LHS->enode_arity = 1;
old_LHS->enode_operands[0] = old_RHS;
```

This code is used in §63.

§**65.** The unary operations are easy in a similar way – they only have one operand, so we always promote V and achieve property (i). A square root is rearranged as a square, and a cube root as a cube. (It's important that everything we do is reversible – we generate exactly those powers which we are able to undo again if necessary.) Unary minus is easier still – we need only move it to the other side; thus $-V = R$ becomes $V = -R$, and `v` again rises.

⟨Rearrange to move v upwards through this unary operator 65⟩ ≡

```
int op = old_LHS->eqn_operation;
switch (op) {
    case UNARY_MINUS_OPERATION:
        eqn->parsed_equation->enode_operands[0] = old_LHS->enode_operands[0];
        eqn->parsed_equation->enode_operands[1] = old_LHS;
        old_LHS->enode_operands[0] = old_RHS;
        break;
    case ROOT_OPERATION:
        eqn->parsed_equation->enode_operands[0] = old_LHS->enode_operands[0];
        eqn->parsed_equation->enode_operands[1] = old_LHS;
        old_LHS->eqn_operation = TIMES_OPERATION;
        old_LHS->enode_arity = 2;
        old_LHS->enode_operands[0] = old_RHS;
        old_LHS->enode_operands[1] = old_RHS;
        break;
    case CUBEROOT_OPERATION:
        eqn->parsed_equation->enode_operands[0] = old_LHS->enode_operands[0];
        eqn->parsed_equation->enode_operands[1] = old_LHS;
        old_LHS->eqn_operation = TIMES_OPERATION;
        old_LHS->enode_arity = 2;
        old_LHS->enode_operands[0] = old_RHS;
        old_LHS->enode_operands[1] = enode_new_op(TIMES_OPERATION);
        old_LHS->enode_operands[1]->enode_operands[0] = old_RHS;
        old_LHS->enode_operands[1]->enode_operands[1] = old_RHS;
        break;
    default: internal_error("unanticipated operator in rearrangement");
}
```

This code is used in §60.

§**66.** And that's the whole rearranger, except for the utility routine which counts instances of the magic variable `v` at or below a given point in the equation tree.

```
int enode_count_var(equation_node *tok, equation_symbol *to_solve) {
    int c = 0, i;
    if (tok == NULL) return c;
    if ((tok->eqn_type == SYMBOL_EQN) && (tok->leaf_symbol == to_solve))
        return 1;
    for (i=0; i<tok->enode_arity; i++)
        c += enode_count_var(tok->enode_operands[i], to_solve);
    return c;
}
```

§**67. Internal test case.** This is a little like those "advise all parties" law exam questions: we parse the equation, then rearrange to solve it for each variable in turn.

```
void eqn_internal_test(int e1, int e2) {
    int i, wh1 = -1, wh2 = -1;
    [[e1, e2 == ... where ... : i --> e1, e2 ... wh1, wh2]];
    equation *eqn = new_equation(e1, e2, TRUE);
    eqn_set_wherewithal(eqn, wh1, wh2);
    examine_equation(eqn);
    begin_reporting_internal_test();
    log_equation_parsed(eqn);
    equation_symbol *ev;
    for (ev = eqn->symbol_list; ev; ev = ev->next) {
        if (eqn_rearrange(eqn, ev) == FALSE)
            LOG("Too hard to rearrange to solve for %s\n", ev->variable_name);
        else {
            LOG("Rearranged to solve for %s:\n", ev->variable_name);
            log_equation_parsed(eqn);
        }
    }
    end_reporting_internal_test();
}
```

The function eqn_internal_test is called from 13/test.

§**68. Indexing and logging.** And finally:

```
void log_equation(equation *eqn) {
    LOG("{$W}", eqn->word_ref1, eqn->word_ref2);
}

void log_equation_parsed(equation *eqn) {
    if (eqn == NULL) LOG("<null>\n");
    else log_equation_node(eqn->parsed_equation);
}

void index_equations(void) {
    int ec = 0; equation *eqn;
    LOOP_OVER(eqn, equation) { ec++; }
    if (ec == 0) return;
    INDEX("<p><b>List of Equations</b> (<i>About equations</i>");
    index_doc_link("EQUATIONS"); INDEX(")<p>\n");
    LOOP_OVER(eqn, equation) {
        int mw = eqn->equation_no_w2;
        if (eqn->equation_name_w2 > mw) mw = eqn->equation_name_w2;
        print_raw_text_to_file(eqn->equation_created_at->word_ref1, mw, ifl);
        index_link(lw_array[eqn->equation_created_at->word_ref1].lw_source);
        INDEX(" (");
        print_raw_text_to_file(eqn->word_ref1, eqn->word_ref2, ifl);
        INDEX(")<br>\n");
    }
}
```

The function log_equation is called from 2/dl.

The function index_equations is invoked by a command in a `.i6t` template file.

Listed-In Relations 10/libp

Purpose

To define the binary predicates corresponding to table columns, and which determine whether a given value is listed in that column.

Definitions

¶1. ...

§**1. Initial stock.** There is none, since no tables or columns exist when Inform starts up.

```
void LISTED_IN_KBP_create_initial_stock(void) {
}
```

The function LISTED_IN_KBP_create_initial_stock is called from 5/bp.

§**2. Subsequent creations.** When a column called, say, "pledged delegate count" appears in one or more tables in the source text, Inform creates a `table_column` structure to represent the common identity of all table columns with this name. (They are required all to share the same kind of value in their entries.) For each different table column, a BP is created to represent the meaning of "X is a pledged delegate count listed in T". Arguably there should just be one super-powerful predicate `listed-in(X, C, T)`, but that would need to be a ternary predicate, not binary, and Inform doesn't at present support those. So we make a one-parameter family of `listed-in-C(X, T)` binary predicates instead.

```
binary_predicate *make_listed_in_predicate(table_column *tc) {
    binary_predicate *bp = make_pair_of_BPs(LISTED_IN_KBP,
        bptd_blank(),
        bptd_new(NULL, kova(TABLE_TY)),
        "listed_in", "lists-in", -1, NULL, NULL,
        sch_new_1d("(ct_1=ExistsTableRowCorr(ct_0=*2,%d,*1))",
            tc_get_column_id(tc)),
        0);
    bp->a_listed_in_predicate = TRUE;
    return bp;
}
```

The function make_listed_in_predicate is called from 10/tab.

§**3.** Once again there is a timing constraint. Tables are created quite early on in Inform's run, but the entries in the columns aren't parsed until much later. Since the kind of value stored in a column is often determined only by looking at those values, it follows that we can't specify what goes into the left-hand term at the time when the column is created. So we fill this in later, instead:

```
void supply_KOV_for_listed_in_tc(binary_predicate *bp, kind_of_value *kov) {
    bp->term_details[0].implies_kov = kov;
    bp->reversal->term_details[1].implies_kov = kov;
}
```

The function supply_KOV_for_listed_in_tc is called from 10/tab.

§4. **Second stock.** By this time, they all exist.

```
void LISTED_IN_KBP_create_second_stock(void) {
}
```

The function LISTED_IN_KBP_create_second_stock is called from 5/bp.

§5. **Typechecking.**

```
int LISTED_IN_KBP_typecheck(binary_predicate *bp,
        kind_of_value **kovs_of_terms, kind_of_value **kovs_required, tc_problem_kit *tck) {
    return DECLINE_TO_MATCH;
}
```

The function LISTED_IN_KBP_typecheck is called from 5/bp.

§6. **Assertion.** These relations cannot be asserted.

```
int LISTED_IN_KBP_assert(binary_predicate *bp,
        world_object *wo0, specification *spec0,
        world_object *wo1, specification *spec1) {
    return FALSE;
}
```

The function LISTED_IN_KBP_assert is called from 5/bp.

§7. **Compilation.** Note the side-effect here: we ensure that the `ct` local variables will be present in the current stack frame, since we're going to need them to hold the table reference for any successful lookup.

```
int LISTED_IN_KBP_compile(int task, binary_predicate *bp, annotated_i6_schema *asch) {
    if (task == TEST_ATOM_TASK) we_need_ct_locals();
    return FALSE;
}
```

The function LISTED_IN_KBP_compile is called from 5/bp.

§8. **Problem message text.**

```
int LISTED_IN_KBP_describe_for_problems(binary_predicate *bp, char *problem_buffer) {
    strcat(problem_buffer, "the listed in relation");
    return TRUE;
}
```

The function LISTED_IN_KBP_describe_for_problems is called from 5/bp.

Interactive Fiction ID 10/ifid

Purpose

Computes and makes available the IFID (Interactive Fiction ID) number for an Inform-generated work of IF, in compliance with the Treaty of Babel.

Template interpreter commands

```
2   {-array:UUID_ARRAY}
```

Definitions

---

§**1.** The Interactive Fiction ID number for an Inform 7-compiled work is the same as the UUID unique ID generated by the Inform 7 application.

UUIDs are not generated within NI, but by the host application: NI expects to read them in the form of the `uuid.txt` file placed in the project bundle by that application. After some agonising, I decided that the Treaty did not actually oblige me to crash NI out if this file did not exist: but in such cases the UUID is empty.

```
define MAX_UUID_LENGTH 128                          the UUID is truncated to this if necessary

char uuid_text[MAX_UUID_LENGTH];
int uuid_read = -1;

int read_uuid(void) {
    FILE *xf; char *fn;
    int i=0; int c;
    if (uuid_read >= 0) return uuid_read;
    uuid_read = 0;
    fn = top_level_filename(UUID_LEAFNAME);
    xf = iso_fopen(fn, "r");
    if (xf == NULL) {
        uuid_text[0] = 0;                           the UUID is the empty string if the file is missing
        return 0;
    }
    while (((c = fgetc(xf)) != EOF)                 the UUID file is plain text, not Unicode
        && (i < MAX_UUID_LENGTH-1))
        uuid_text[i++] = toupper(c);
    fclose(xf);
    uuid_text[i] = 0;
    uuid_read = i;
    return i;
}
```

The function read_uuid is called from 10/bib.

§**2.** The IFID is written into the compiled story file, too, both in order that it can be printed by the VERSION command and to brand the file so that it can still be identified even if it loses touch with its iFiction record. We store the IFID in plain text, with a "magic string" identifier around it, in byte-accessible memory.

```
void compile_UUID_ARRAY_array(OUTPUT_STREAM) {
    int i;
    read_uuid();
    WRITE("Array UUID_ARRAY string \"UUID://");
    for (i=0; uuid_text[i]; i++) WRITE("%c", toupper(uuid_text[i]));
    WRITE("//\";\n");
}
```

The function compile_UUID_ARRAY_array is invoked by a command in a `.i6t` template file.

Bibliographic Data 10/bib

Purpose

To manage the special quantities providing bibliographic data on the work of IF being generated (title, author's name and so forth); to write the iFiction record for the work of IF compiled, its release instructions and its picture manifest, if any.

Template interpreter commands

```
4   {-callv:index_library_card}
5   {-callv:write_ifiction_and_blurb}
21   {-callv:compile_bibliographic_i6_constants}
```

Definitions

¶1. Much of this section is best understood by reference to the Treaty of Babel, a cross-IF-system standard for bibliographic data and packaging agreed between the major IF design systems in 2006. Inform aims to comply fully with the Treaty and the code below should be maintained as such.

The bibliographic data for the story is kept in the following quantities, which are used to build the iFiction record and the releasing blurb at the end of a successful compilation.

```
quantity *story_title = NULL;
quantity *story_author = NULL;
quantity *story_headline = NULL;
quantity *story_genre = NULL;
quantity *story_description = NULL;
quantity *story_release_number = NULL;
quantity *story_creation_year = NULL;
int episode_number = -1;                    for a work which is part of a numbered series
char *series_name = NULL;
```

¶2. Auxiliary files are not really files to NI at all: simply names passed along. They are the auxiliary files included in the iFiction record generated for a released project, if the source asks to do so: they might for instance be maps or booklets which the author intends to accompany the final story file. (Because they are treated only as names and are never opened, the following structure contains no file handles.)

```
typedef struct auxiliary_file {
    char *leafname_in_materials_folder;                    e.g., "Collegio.pdf"
    char *brief_description;                               e.g., "Collegio Magazine"
    MEMORY_MANAGEMENT
} auxiliary_file;
```

The structure auxiliary_file is private to this section.

---

§**1.** Here we parse the special titling line at the top of the text source, setting two initial values for the bibliographic variables: `story_title` and `story_author`.

```
sentence_handler BIBLIOGRAPHIC_SH_handler =
    { BIBLIOGRAPHIC_NT, -1, 2, bibliographic_data };

void bibliographic_data(parse_node *PN) {
    int w1, w2, aw1 = -1, aw2 = -1, i;
    [[w1, w2 <-- PN]];
    [[w1, w2 == ... by ... : i --> w1, w2 ... aw1, aw2]];
    if ((is_kova(is_a_literal(w1, w2), TEXT_TY) == FALSE) &&
        (is_kova(is_a_literal(w1, w2), TEXT_ROUTINE_TY) == FALSE)) {
        sentence_problem(_P_(C10BadTitleSentence),
            "the initial bibliographic sentence can only be a title in double-quotes",
            "possibly followed with 'by' and the name of the author.");
    }
    if (story_title && story_author) {
        specification *the_title = parse_expression(w1, w1, VALUE_EXPCON);
        initialise_global_variable(story_title, the_title, NULL);
        if (aw1 >= 0) {
            char author_buffer[1024];
            if (is_kova(is_a_literal(aw1, aw2), TEXT_TY) == FALSE) {
                sprintf(author_buffer, "\"");
                print_raw_text_to_string(aw1, aw2,
                    author_buffer+strlen(author_buffer));
                for (i=1; author_buffer[i]; i++)
                    if (author_buffer[i] == '\"') author_buffer[i] = '\'';
                sprintf(author_buffer+strlen(author_buffer), "\" ");
                feed_into_lexer(author_buffer, FALSE, FALSE);
                aw1 = lexer_feed_w1; aw2 = lexer_feed_w2;
            }
            specification *the_author = parse_expression(aw1, aw1, VALUE_EXPCON);
            initialise_global_variable(story_author, the_author, NULL);
        }
    } else internal_error("story title and author quantities not created");
}

int story_author_is(char *p) {
    if ((story_author) && (qty_has_initial_value_set(story_author))) {
```

```
        specification *spec = qty_get_initial_value(story_author);
        spec_set_kind_of_value(spec, kova(TEXT_TY));
        int result = FALSE;
        int b = divert_constant_text_bibliographically;
        TEMPORARY_STREAM;
        divert_constant_text_bibliographically = TRUE;
        spec_compile(TEMP, spec);
        divert_constant_text_bibliographically = b;
        if (strcmp(p, STREAM_TEXT(TEMP)) == 0) result = TRUE;
        CLOSE_TEMPORARY_STREAM;
        return result;
    }
    return FALSE;
}
```

The function story_author_is is called from 4/ext.

§**2. Episodes in a series.** This sets the two global variables for episode number and series title, which are handled less grandly than the quantities above.

```
sentence_handler EPISODE_SH_handler =
    { SENTENCE_NT, EPISODE_VB, 1, set_episode_data };

void set_episode_data(parse_node *pn) {
    int w1, w2, of1, of2, x1, x2, i;
    [[w1, w2 <-- pn->down->next->next]];
    if ([[w1, w2 == ... of ... : i --> x1, x2 ... of1, of2]] &&
        (is_kova(is_a_literal(x1, x2), NUMBER_TY)) &&
        (is_kova(is_a_literal(of1, of2), TEXT_TY))) {
        is_a_literal(x1, x1);
        episode_number = last_literal_evaluated;
        dequote_word(of2);
        series_name = lw_array[of2].lw_text;
        return;
    }
    LOG("Found data <$W>\n", w1, w2);
    sentence_problem(_P_(C10BadEpisode),
        "this is not the right way to specify how the story "
        "fits into a larger narrative",
        "and should take the form 'The story is episode 2 of "
        "\"Belt of Orion\", where the episode number has to be a "
        "whole number 0, 1, 2, ... and the series name has to be "
        "plain text without [substitutions].");
}
```

§**3. Releasing instructions.** The following somewhat miscellaneous variables hold the instructions given in the source text for how to release the story file – the content of the "Release along with..." sentence, in fact. We then give the routine which parses this sentence, setting the relevant variables.

```
int release_website = FALSE;                                    Release along with a website?
char *website_template_leafname = "Standard";                   If so, the template name for it
int release_booklet = FALSE;                                    Release along with introductory booklet?

§4. **The Library Card.** The Library Card is part of the Contents index, and is intended as a natural way to present bibliographic data to the user. In effect, it's a simplified form of the iFiction record, without the XML overhead and without the technicalities handled automatically by NI.

```
int write_bibliographic_datum(OUTPUT_STREAM, quantity *q, int desc_mode) {
    if (q == NULL) return FALSE;
    if (qty_has_initial_value_set(q) == FALSE) return FALSE;
    TEMPORARY_STREAM;
    compile_literal_text(TEMP, qty_treat_as_plain_text_word(q));
    if (STREAM_EXTENT(TEMP) > 0) {
        if (desc_mode) WRITE("<description>");
        STREAM_COPY(OUT, TEMP);
        if (desc_mode) WRITE("</description>\n");
    }
    CLOSE_TEMPORARY_STREAM;
    return TRUE;
}

void library_card_entry(char *field, quantity *q, char *t) {
    char *font = "<font face=\"courier\" size=2 color=\"#000080\">";
    first_html_column(ifl, 0);
    INDEX("%s%s</font>", font, field);
    next_html_column(ifl, 0);
    INDEX("%s<b>", font);
    divert_constant_text_bibliographically = TRUE;
    BEGIN_COMPILATION_MODE;
    COMPILATION_MODE_ENTER(COMPILE_TEXT_TO_XML_CMODE);
    if (write_bibliographic_datum(ifl, q, (q==story_description)?TRUE:FALSE)
        == FALSE) INDEX("%s", t);
    divert_constant_text_bibliographically = FALSE;
    END_COMPILATION_MODE;
    INDEX("</b></font>");
    end_html_row(ifl);
}

void index_library_card(void) {
    auxiliary_file *af;
    INDEX("<p><hr><p>");
    index_anchor("LCARD");
    INDEX("<b>Library Card</b> (<i>About library cards:</i>");
    index_doc_link("LCARDS"); INDEX(")<p>\n");
    begin_html_table(ifl, "cornsilk", FALSE, 1, 3, 3, 0, 0);
    library_card_entry("Story title", story_title, "Untitled");
    library_card_entry("Story author", story_author, "Anonymous");
    library_card_entry("Story headline", story_headline, "An Interactive Fiction");
    library_card_entry("Story genre", story_genre, "Fiction");
    if (episode_number >= 0) {
        char episode_text[MAX_STRING_LENGTH+20];
        sprintf(episode_text, "%d of %s", episode_number, series_name);
        library_card_entry("Episode", NULL, episode_text);
    }
    library_card_entry("Release number", story_release_number, "1");
    library_card_entry("Story creation year", story_creation_year, "(This year)");
    library_card_entry("IFID number", NULL, uuid_text);
    library_card_entry("Story description", story_description, "None");
```

```
    LOOP_OVER(af, auxiliary_file) {
        library_card_entry(af->leafname_in_materials_folder, NULL,
            af->brief_description);
    }
    end_html_table(ifl);
    INDEX("<p>\n");
    write_current_VM(ifl);
    index_VM_usage();
}
```

The function index_library_card is invoked by a command in a `.i6t` template file.

§**5. The main metadata routine.** Here we combine writing the iFiction record and the release instructions. (In a single routine, since they share the need to know about certain external files.)

```
void write_ifiction_and_blurb(void) {
    STREAM xf_struct; STREAM *xf = &xf_struct;
    char *fn;
    int i, cover_picture_number = 0;
    char materials_folder[MAX_FILENAME_LENGTH];
    char cover_filename[MAX_FILENAME_LENGTH];
    char *cover_art_format = NULL;
    char header[64];
    FILE *COVER_FILE;
    unsigned int width, height;
    char *story_format = "zcode";
    char *manifest_filename;
    if (release_cover) cover_picture_number = 1;
    if ((story_filename_extension) &&
        (strcmp(story_filename_extension, "ulx") == 0))
        story_format = "glulx";
    ⟨WIB - Ensure Materials folder if needed 6⟩;
    ⟨WIB - Check cover art image if any 7⟩;
    ⟨WIB - Read header of existing story file if present 8⟩
    read_uuid();
    divert_constant_text_bibliographically = TRUE;
    ⟨WIB - Write iFiction record 9⟩;
    ⟨WIB - Write release blurb 10⟩;
    ⟨WIB - Write manifest file 11⟩;
    divert_constant_text_bibliographically = FALSE;
}
```

The function write_ifiction_and_blurb is invoked by a command in a `.i6t` template file.

§6. Some forms of release need to take files from, or put files into, a subfolder called Release of the project's associated Materials folder. This is where we read (and if necessary create) that folder.

⟨WIB - Ensure Materials folder if needed 6⟩ ≡

```
if (bundle_name) strcpy(materials_folder, bundle_name);
else materials_folder[0] = 0;
i = strlen(materials_folder)-1;
while ((i>0) && (materials_folder[i] != '.')) i--;
if (i>0) strcpy(materials_folder+i, " Materials");
if ((release_website) || (release_booklet) || (release_cover) ||
    (release_solution) || (existing_story_file) ||
    (NUMBER_CREATED(blorb_figure) > 1)) {
    if ((materials_folder[0] == 0) ||
        (platform_specific_mkdir(materials_folder) == FALSE)) {
        release_problem(_P_(Untestable),
            "In order to release the story file along with other "
            "resources, I tried to create a folder alongside this "
            "Inform project, but was unable to do so. The folder "
            "was to have been called",
            materials_folder);
        return;
    }
    if (materials_folder[0]) {
        char release_folder[MAX_FILENAME_LENGTH];
        sprintf(release_folder, "%s%cRelease", materials_folder, FOLDER_SEPARATOR);
        if (platform_specific_mkdir(release_folder) == FALSE) {
            release_problem(_P_(Untestable),
                "In order to release the story file along with other "
                "resources, I tried to create a folder alongside this "
                "Inform project, but was unable to do so. The folder "
                "was to have been called",
                release_folder);
            return;
        }
    }
}
```

This code is used in §5.

§**7.** Using the utility routines above, we find out the format of the cover art and see that its dimensions conform to Treaty of Babel requirements.

⟨WIB - Check cover art image if any 7⟩ ≡

```
if (release_cover) {
    unsigned int rv = 0;
    cover_art_format = "jpg";
    sprintf(cover_filename, "%s%cCover.jpg", materials_folder, FOLDER_SEPARATOR);
    COVER_FILE = iso_fopen(cover_filename, "rb" );
    if (COVER_FILE) {
        rv = get_jpg_dimensions(COVER_FILE, &width, &height);
        fclose(COVER_FILE);
        if (rv == 0) {
            release_problem(_P_(Untestable),
                "The cover image seems not to be a JPEG despite the name",
                cover_filename);
            return;
        }
    }
    if (rv == 0) {
        sprintf(cover_filename, "%s%cCover.png", materials_folder, FOLDER_SEPARATOR);
        COVER_FILE = iso_fopen(cover_filename, "rb" );
        if (COVER_FILE == NULL) {
            current_sentence = cover_filename_sentence;
            release_problem_at_sentence(_P_(Untestable),
                "The release instructions said that there is a cover image "
                "to attach to the story file, but I was unable to find it, "
                "having looked for both 'Cover.png' and 'Cover.jpg' in the "
                "'Materials' folder for this project", cover_filename);
            return;
        }
        cover_art_format = "png";
        rv = get_png_dimensions(COVER_FILE, &width, &height);
        fclose(COVER_FILE);
        if (rv == 0) {
            release_problem(_P_(Untestable),
                "The cover image seems not to be a PNG despite the name",
                cover_filename);
            return;
        }
    }
    if ((width < 120) || (width > 1200) || (height < 120) || (height > 1200)) {
        release_problem(_P_(Untestable),
            "The height and width of the cover image, in pixels, must be "
            "between 120 and 1024 inclusive",
            cover_filename);
        return;
    }
    if ((width > 2*height) || (height > 2*width)) {
        release_problem(_P_(Untestable),
            "We recommend a square cover image, but at any rate it is "
            "required to be no more rectangular than twice as wide as it "
            "is high (or vice versa)",
            cover_filename);
```

```
            return;
        }
    }
```

This code is used in §5.

§8.

⟨WIB - Read header of existing story file if present 8⟩ ≡

```
    if (existing_story_file) {
        FILE *STORYF;
        int i;
        char story_filename[2*MAX_FILENAME_LENGTH];
        if (story_filename_extension == NULL)
            sprintf(story_filename, "%s%cstory.z5",
                materials_folder, FOLDER_SEPARATOR);
        else
            sprintf(story_filename, "%s%cstory.%s",
                materials_folder, FOLDER_SEPARATOR, story_filename_extension);
        STORYF = iso_fopen(story_filename, "rb");
        if (STORYF == NULL) {
            fatal_error2("Unable to find the promised existing story file",
                story_filename);
        }
        for (i=0; i<0x40; i++) header[i] = fgetc(STORYF);
        fclose(STORYF);
    }
```

This code is used in §5.

§9. For the format of this file, see the Treaty of Babel.

⟨WIB - Write iFiction record 9⟩ ≡

```
    fn = top_level_filename(METADATA_LEAFNAME);
    if (STREAM_OPEN_TO_FILE(xf, fn, UTF8_ENC) == FALSE) fatal_error2("Can't open metadata file",
fn);
    BEGIN_COMPILATION_MODE;
    COMPILATION_MODE_ENTER(COMPILE_TEXT_TO_XML_CMODE);
    write_ifiction_record(xf, story_format, header,
        cover_picture_number, cover_art_format, height, width);
    END_COMPILATION_MODE;
    STREAM_CLOSE(xf);
```

This code is used in §5.

§10. The release file is a set of instructions for how to turn the compiled story file, together with any picture resources and iFiction record, into a "blorb": one of the components of Inform 7 is its "releasing agent", presently `cblorb`, whose task is to act on the instructions we are about to write. This cannot be done directly by NI since the story file itself does not exist at any point during NI's run (NI merely produces I6 source code, which has to be run through I6 to obtain the story file). Besides, it makes good sense to separate these functions.

The format for the release file is an extension of the "blurb" format documented in the *Inform Designer's Manual*, fourth edition (the "DM4"). At some point we intend to publish a description of blurb 2.0, this extended version, but at present the format is in flux, and we are contemplating replacing the releasing agent with a better one; which may well change the blurb specification.

Note that the code below does not generate an `author` blurb instruction, which would lead to an AUTH chunk in the final blorb. This is partly because the AUTH chunk is now obsolete in the wake of the Treaty of Babel, but also because it avoids problems with Unicode: an AUTH can only contain plainest ASCII, whereas the author's name known to NI may very well use characters not representable in ASCII. There is no good way round this: so, farewell AUTH.

Similarly, we do not supply a release number. The release number of a blorb has a different meaning from that of the story file embedded in it: the number refers to the release of the picture and sound resources found in the blorb, and NI knows nothing about this, so it makes no comment.

⟨WIB - Write release blurb 10⟩ ≡

```
fn = top_level_filename(BLURB_LEAFNAME);
if (STREAM_OPEN_TO_FILE(xf, fn, ISO_ENC) == FALSE)
    fatal_error2("Can't open blurb file", fn);
write_release_blurb(xf, materials_folder, cover_picture_number, cover_art_format);
STREAM_CLOSE(xf);
```

This code is used in §5.

§11.

⟨WIB - Write manifest file 11⟩ ≡

```
manifest_filename = top_level_filename(MANIFEST_LEAFNAME);
if (STREAM_OPEN_TO_FILE(xf, manifest_filename, UTF8_ENC) == FALSE)
    fatal_error2("Can't open manifest file", fn);
fig_write_picture_manifest(xf, release_cover);
STREAM_CLOSE(xf);
```

This code is used in §5.

§12.

```
void write_ifiction_record(OUTPUT_STREAM, char *story_format, char *header,
    int cover_picture_number, char *cover_art_format, int height, int width) {

        (the_present->tm_year)-100, (the_present->tm_mon)+1, the_present->tm_mday);
    encode_constant_text_bibliographically = FALSE;
}
```

The function compile_bibliographic_i6_constants is invoked by a command in a `.i6t` template file.

Figures 10/fig

Purpose

To register the names associated with picture resource numbers, which are defined to allow the final story file to display pictures, and to produce the thumbnail index of figures.

10/fig.§3-5 Blurb and manifest; §6 Thumbnail Index

Template interpreter commands

```
5   {-array:tableoffigures}
6   {-callv:index_figures}
```

Definitions

¶1. To be viable, figures have to be of an image format which Blorb recognises, and in any case we only allow two formats: JPEG and PNG.

```
typedef struct blorb_figure {
    int word_ref1, word_ref2;                    text of figure name
    int leafname_word;                           word number of text like "plant.jpg"
    int figure_number;                           resource number of this picture inside Blorb
    MEMORY_MANAGEMENT
} blorb_figure;
```

The structure blorb_figure is private to this section.

---

§**1.** Resources in a Blorb file have unique ID numbers which are positive integers, but these are not required to start from 1, nor to be contiguous. For Inform, ID number 1 is reserved for the cover image (whether or not any cover image is provided: it is legal for there to be figures but no cover, and vice versa). Other figures, and sound effects, then mix freely as needed from ID number 3 on upwards. We skip 2 so that it can be guaranteed that no sound resource has ID 1 or 2: this is to help people trying to play sounds in the Z-machine, where operand 1 or 2 in the `@sound` opcode signifies not a sound resource number but a long or short beep. If a genuine sound effect had resource ID 1 or 2, therefore, it would be unplayable on the Z-machine.

```
int next_free_resource_ID = 3;

int get_next_free_blorb_resource_ID(void) {
    return next_free_resource_ID++;
}
```

The function get_next_free_blorb_resource_ID is called from 10/sfx.

§**2.** Figure allocation now follows.

```
sentence_handler FIGURE_SH_handler =
    { SENTENCE_NT, FIGURE_VB, 1, handle_figure_definition };
void handle_figure_definition(parse_node *p) {
    register_figure(p->down->next->word_ref1,
        p->down->next->word_ref2,
        p->down->next->next->word_ref1,
        p->down->next->next->word_ref2);
}
void register_figure(int f1, int f2, int fn1, int fn2) {
    blorb_figure *bf; meaning_list *ml; int wn;
    if [[fn1, fn2 == of cover art]] {
        wn = -1;
    } else {
        if (is_kova(is_a_literal(fn1, fn2), TEXT_TY) == FALSE) {
            sentence_problem(_P_(C10PictureNotTextual),
                "a figure can only be declared as a quoted file name",
                "which should be the name of a JPEG or PNG image inside the "
                "project's Materials folder. For instance, 'Figure 2 is the "
                "file \"Crossed Swords.png\".'");
            return;
        }
        dequote_word(fn1);
        wn = fn1;
    }
    bf = CREATE(blorb_figure);
    bf->leafname_word = wn;
    bf->word_ref1 = f1; bf->word_ref2 = f2;
    if (wn >= 0)
        bf->figure_number = get_next_free_blorb_resource_ID();
    else
        bf->figure_number = 1;
    LOGIF(FIGURE_CREATIONS, "Created figure <$W> = filename '%s' = resource ID %d\n",
        f1, f2, (wn>=0)?lw_array[wn].lw_text:"<cover art>", bf->figure_number);
    ml = SP_excerpt(MISCELLANEOUS_MC, f1, f2);
    if ((ml != NULL) && (em_get_secondary_code(ml_meaning(ml)) == FIGURE_SMC)) {
        sentence_problem(_P_(C10PictureDuplicate),
            "this is already the name of a Figure",
            "so there must be some duplication somewhere.");
        return;
    }
    register_excerpt_meaning(
        MISCELLANEOUS_MC, FIGURE_SMC, f1, f2, STORE_POINTER_blorb_figure(bf));
}
int fig_get_resource_ID(blorb_figure *bf) {
    return bf->figure_number;
}
```

The function fig_get_resource_ID is called from 5/lit.

§**3. Blurb and manifest.** The picture manifest is used by the implementation of Glulx within the Inform application to connect picture ID numbers with filenames relative to the Materials folder for its project.

```
void fig_write_picture_manifest(OUTPUT_STREAM, int releasing_cover) {
    blorb_figure *bf;
    WRITE("<?xml version=\"1.0\" encoding=\"UTF-8\"?>\n");
    WRITE("<!DOCTYPE plist PUBLIC \"-//Apple Computer//DTD PLIST 1.0//EN\" "
        "\"http://www.apple.com/DTDs/PropertyList-1.0.dtd\">\n");
    WRITE("<plist version=\"1.0\">\n"); INDENT;
    WRITE("<dict>\n"); INDENT;
    WRITE("<key>Graphics</key>\n");
    WRITE("<dict>\n"); INDENT;
    if (releasing_cover) {
        WRITE("<key>1</key>\n");
        WRITE("<string>Cover.jpg</string>\n");
    }
    LOOP_OVER(bf, blorb_figure) {
        if (bf->leafname_word == -1) continue;
        WRITE("<key>%d</key>\n", bf->figure_number);
        WRITE("<string>Figures%c%s</string>\n", FOLDER_SEPARATOR, lw_array[bf->leafname_word].lw_text);
    }
    OUTDENT; WRITE("</dict>\n");
    sfx_write_sounds_manifest(OUT);
    OUTDENT; WRITE("</dict>\n");
    OUTDENT; WRITE("</plist>\n");
}
```

The function fig_write_picture_manifest is called from 10/bib.

§**4.** The following writes Blurb commands for all of the figures, but not for the cover art, which is handled by Bibliographic Data.

```
void fig_write_blurb_commands(OUTPUT_STREAM, char *resources) {
    blorb_figure *bf;
    LOOP_OVER(bf, blorb_figure) {
        if (bf->leafname_word == -1) continue;
        WRITE("picture %d \"%s%cFigures%c%s\"\n",
            bf->figure_number, resources,
            FOLDER_SEPARATOR, FOLDER_SEPARATOR, lw_array[bf->leafname_word].lw_text);
    }
}
```

The function fig_write_blurb_commands is called from 10/bib.

§5.

```
void compile_tableoffigures_array(OUTPUT_STREAM) {
    WRITE("Array TableOfFigures --> ");
    blorb_figure *bf;
    LOOP_OVER(bf, blorb_figure) WRITE("%d ", bf->figure_number);
    WRITE(" 0 0;\n");
    WRITE("[ PrintFigureName f;\n"); INDENT;
    WRITE("switch(f) {\n"); INDENT;
    LOOP_OVER(bf, blorb_figure) {
        WRITE("%d: print \"", bf->figure_number);
        print_raw_text_to_file(bf->word_ref1, bf->word_ref2, OUT);
        WRITE("\";\n");
    }
    WRITE("default: print \"<no-such-figure>\";\n");
    OUTDENT; WRITE("}\n");
    OUTDENT; WRITE("];\n");
}
```

The function compile_tableoffigures_array is invoked by a command in a `.i6t` template file.

§6. **Thumbnail Index.** The index is presented with thumbnails of a given pixel width, which the HTML renderer automatically scales to fit. Height is adjusted so as to match this width, preserving the aspect ratio.

define THUMBNAIL_WIDTH 80

```
void index_figures(void) {
    blorb_figure *bf; int i; FILE *FIGURE_FILE;
    char resources[MAX_FILENAME_LENGTH];
    char image_filename[MAX_FILENAME_LENGTH];
    char line2[MAX_FILENAME_LENGTH];
    int rv;
    if (NUMBER_CREATED(blorb_figure) < 2) return;                    cover art always creates 1
    strcpy(resources, bundle_name);
    i = strlen(resources)-1;
    while ((i>0) && (resources[i] != '.')) i--;
    if (i>0) sprintf(resources+i, " Materials%cFigures", FOLDER_SEPARATOR);
    INDEX("<p><b>List of Figures</b> (<i>About figures</i>");
    index_doc_link("FIGURES"); INDEX(")<p>\n");
    begin_html_table(ifl, "#ffffff", TRUE, 0, 0, 0, 0, 0);
    LOOP_OVER(bf, blorb_figure) {
        unsigned int width, height;
        if (bf->leafname_word == -1) continue;
        sprintf(image_filename, "%s%c%s", resources, FOLDER_SEPARATOR,
            lw_array[bf->leafname_word].lw_text);
        rv = 0;
        FIGURE_FILE = iso_fopen(image_filename, "rb");
        if (FIGURE_FILE) {

```

The function index_figures is invoked by a command in a `.i6t` template file.

Sound Effects 10/sfx

Purpose

To register the names associated with sound resource numbers, which are defined to allow the final story file to play sound effects, and to produce the index of sound effects.

10/sfx.§1-3 Blurb and manifest; §4 Sounds Index

Template interpreter commands

```
3   {-array:tableofsounds}
4   {-callv:index_sounds}
```

Definitions

¶1. To be viable, sound files have to be of a format which Blorb recognises, and in any case we only allow two formats: AIFF (uncompressed) and OGG (compressed).

Sound effects and images have unique ID numbers (i.e., we cannot have both sound number 45 and also image 45): these are positive integers, but are not required to start from 1, nor to be contiguous. For Inform, ID number 1 is reserved for the cover image (whether or not any cover image is provided: it is legal for there to be figures but no cover, and vice versa). Resource numbers are then numbered contiguously upwards from 2.

```
typedef struct blorb_sound {
    int word_ref1, word_ref2;                    text of sound name
    int sfx_leafname_word;                       word number of text like "eerie.ogg"
    int sound_number;                            resource number of this picture inside Blorb
    MEMORY_MANAGEMENT
} blorb_sound;
```

The structure blorb_sound is private to this section.

```
sentence_handler SOUND_SH_handler =
    { SENTENCE_NT, SOUND_VB, 1, handle_sound_definition };
void handle_sound_definition(parse_node *p) {
    register_sound(p->down->next->word_ref1,
        p->down->next->word_ref2,
        p->down->next->next->word_ref1,
        p->down->next->next->word_ref2);
}
void register_sound(int f1, int f2, int fn1, int fn2) {
    blorb_sound *bs; meaning_list *ml; int wn;
    if (is_kova(is_a_literal(fn1, fn2), TEXT_TY) == FALSE) {
        sentence_problem(_P_(C10SoundNotTextual),
            "a sound effect can only be declared as a quoted file name",
            "which should be the name of an AIFF or OGG file inside the "
            "Sounds subfolder of the project's Materials folder. For "
            "instance, 'Sound of Swordplay is the file "
            "\"Crossed Swords.aiff\".'");
        return;
```

```
    }
    dequote_word(fn1);
    wn = fn1;
    bs = CREATE(blorb_sound);
    bs->sfx_leafname_word = wn;
    bs->word_ref1 = f1; bs->word_ref2 = f2;
    bs->sound_number = get_next_free_blorb_resource_ID();
    LOGIF(FIGURE_CREATIONS, "Created sound effect <$W> = filename '%s' = resource ID %d\n",
        f1, f2, lw_array[wn].lw_text, bs->sound_number);
    ml = SP_excerpt(MISCELLANEOUS_MC, f1, f2);
    if ((ml != NULL) && (em_get_secondary_code(ml_meaning(ml)) ==
        SOUND_EFFECT_SMC)) {
        sentence_problem(_P_(C10SoundDuplicate),
            "this is already the name of a sound effect",
            "so there must be some duplication somewhere.");
        return;
    }
    register_excerpt_meaning(
        MISCELLANEOUS_MC, SOUND_EFFECT_SMC, f1, f2,
        STORE_POINTER_blorb_sound(bs));
}

int sfx_get_resource_ID(blorb_sound *bs) {
    return bs->sound_number;
}
```

The function sfx_get_resource_ID is called from 5/lit.

§**1. Blurb and manifest.** The sounds manifest is used by the implementation of Glulx within the Inform application to connect picture ID numbers with filenames relative to the `Materials/Sounds` folder for its project. (It's part of the XML manifest file created from `Figures.w`.)

```
void sfx_write_sounds_manifest(OUTPUT_STREAM) {
    blorb_sound *bs;
    if (NUMBER_CREATED(blorb_sound) == 0) return;
    WRITE("<key>Sounds</key>\n");
    WRITE("<dict>\n"); INDENT;
    LOOP_OVER(bs, blorb_sound) {
        WRITE("<key>%d</key>\n", bs->sound_number);
        WRITE("<string>Sounds%c%s</string>\n", FOLDER_SEPARATOR, lw_array[bs->sfx_leafname_word].lw_text);
    }
    OUTDENT; WRITE("</dict>\n");
}
```

The function sfx_write_sounds_manifest is called from 10/fig.

§**2.** The following writes Blurb commands for all of the sounds.

```
void sfx_write_blurb_commands(OUTPUT_STREAM, char *resources) {
    blorb_sound *bs;
    LOOP_OVER(bs, blorb_sound) {
        WRITE("sound %d \"%s%cSounds%c%s\"\n",
            bs->sound_number, resources,
            FOLDER_SEPARATOR, FOLDER_SEPARATOR, lw_array[bs->sfx_leafname_word].lw_text);
    }
}
```

The function sfx_write_blurb_commands is called from 10/bib.

§**3.**

```
void compile_tableofsounds_array(OUTPUT_STREAM) {
    WRITE("Array TableOfSounds --> ");
    blorb_sound *bs;
    LOOP_OVER(bs, blorb_sound) WRITE("%d ", bs->sound_number);
    WRITE(" 0 0;\n");
    WRITE("[ PrintSoundName f;\n"); INDENT;
    WRITE("switch(f) {\n"); INDENT;
    WRITE("0: print \"<silence>\";\n");
    LOOP_OVER(bs, blorb_sound) {
        WRITE("%d: print \"", bs->sound_number);
        print_raw_text_to_file(bs->word_ref1, bs->word_ref2, OUT);
        WRITE("\";\n");
    }
    WRITE("default: print \"<no-such-sound>\";\n");
    OUTDENT; WRITE("}\n");
    OUTDENT; WRITE("];\n");
}
```

The function compile_tableofsounds_array is invoked by a command in a `.i6t` template file.

§**4. Sounds Index.** The index is only a little helpful for sounds.

```
void index_sounds(void) {
    blorb_sound *bs; int i; FILE *SOUND_FILE;
    char resources[MAX_FILENAME_LENGTH];
    char image_filename[MAX_FILENAME_LENGTH];
    char line2[MAX_FILENAME_LENGTH];
    int rv;
    if (NUMBER_CREATED(blorb_sound) == 0) return;
    strcpy(resources, bundle_name);
    i = strlen(resources)-1;
    while ((i>0) && (resources[i] != '.')) i--;
    if (i>0) sprintf(resources+i, " Materials%cSounds", FOLDER_SEPARATOR);
    INDEX("<p><b>List of Sounds</b> (<i>About sounds</i>");
    index_doc_link("SOUNDS"); INDEX(")<p>\n");

        if ((ml != NULL) &&
            (em_get_secondary_code(ml_meaning(ml)) == EXTERNAL_FILE_SMC)) {
            sentence_problem(_P_(C10FilenameDuplicate),
                "this is already the name of a file",
                "so there must be some duplication somewhere.");
            return;
        }
        register_excerpt_meaning(
            MISCELLANEOUS_MC, EXTERNAL_FILE_SMC,
                f1, f2, STORE_POINTER_external_file(exf));
        isn_compose_identifier(exf->exf_I6_identifier, 'X', exf->allocation_id,
            exf->word_ref1, exf->word_ref2);
}
```

§2. **I6 arrays of file structures.** External files are written in I6 as their array names:

```
void compile_exf_constant(OUTPUT_STREAM, int id) {
    external_file *exf;
    LOOP_OVER(exf, external_file) {
        if (exf->allocation_id == id) {
            WRITE("%s", exf->exf_I6_identifier);
            return;
        }
    }
    LOG("ID: %d\n", id);
    internal_error("no exf structure with this ID");
}
```

The function compile_exf_constant is called from 7/vasp.

§3. And the following declares the arrays:

```
void external_file_arrays(OUTPUT_STREAM) {
    external_file *exf;
    WRITE("Array TableOfExternalFiles --> ");
    LOOP_OVER(exf, external_file) WRITE("%s ", exf->exf_I6_identifier);
    WRITE("0 0;\n");
    LOOP_OVER(exf, external_file) {
        WRITE("Array %s --> AUXF_MAGIC_VALUE AUXF_STATUS_IS_UNUSED %s 0 0\n",
            exf->exf_I6_identifier,
            (exf->file_is_binary)?"true":"false");
        INDENT;
        WRITE("%s ", lw_array[exf->unextended_filename].lw_rawtext);
        switch (exf->file_ownership) {
            case OWNED_BY_THIS_PROJECT:
                WRITE("UUID_ARRAY;\n");
                break;
            case OWNED_BY_ANOTHER_PROJECT:
                WRITE("NULL;\n");
                break;
            case OWNED_BY_SPECIFIC_PROJECT:
                WRITE("IFID_ARRAY_%d;\n", exf->allocation_id);
                WRITE("Array IFID_ARRAY_%d string \"//%s//\";\n",
                    exf->allocation_id, exf->IFID_of_owner);
                break;
        }
        OUTDENT;
    }
    WRITE("[ PrintExternalFileName f;\n"); INDENT;
    WRITE("switch(f) {\n"); INDENT;
    LOOP_OVER(exf, external_file) {
        WRITE("%s: print \"", exf->exf_I6_identifier);
        print_raw_text_to_file(exf->word_ref1, exf->word_ref2, OUT);
        WRITE("\";\n");
    }
    WRITE("default: print \"<no-such-file>\";\n");
    OUTDENT; WRITE("}\n");
    OUTDENT; WRITE("];\n");
```

```
}
```

The function external_file_arrays is invoked by a command in a .i6t template file.

§4. **External Files Index.** More or less perfunctory, but still of some use, if only as a list.

```
void index_external_files(void) {
    external_file *exf;
    if (NUMBER_CREATED(external_file) == 0) return;
    INDEX("<p><b>List of External Files</b> (<i>About files</i>");
    index_doc_link("EFILES"); INDEX(")<p>\n");
    begin_html_table(ifl, "#ffffff", TRUE, 0, 0, 0, 0, 0);
    LOOP_OVER(exf, external_file) {
        first_html_column(ifl, THUMBNAIL_WIDTH+10);
        if (exf->file_is_binary)
            INDEX("<img border=\"0\" src=\"inform:/doc_images/exf_binary.png\"> ");
        else {
            INDEX("<img border=\"0\" src=\"inform:/doc_images/exf_text.png\"> ");
        }
        next_html_column(ifl, 0);
        print_raw_text_to_file(exf->word_ref1, exf->word_ref2, ifl);
        index_link(lw_array[exf->word_ref1].lw_source);
        INDEX("<br>\nFilename: %s %s- owned by ",
            (exf->file_is_binary)?"- binary ":"",
            lw_array[exf->unextended_filename].lw_text);
        switch (exf->file_ownership) {
            case OWNED_BY_THIS_PROJECT: INDEX("this project"); break;
            case OWNED_BY_ANOTHER_PROJECT: INDEX("another project"); break;
            case OWNED_BY_SPECIFIC_PROJECT:
                INDEX("project with IFID number <b>%s</b>",
                    exf->IFID_of_owner);
                break;
        }
        end_html_row(ifl);
    }
    end_html_table(ifl);
    INDEX("<p>");
}
```

The function index_external_files is invoked by a command in a .i6t template file.

Inform 6 Inclusions 10/isin

Purpose

To include Inform 6 code almost verbatim in the output of NI, as instructed by low-level Inform 7 sentences.

Template interpreter commands

```
2   {-callv:compile_use_options}
2   {-routine:TestUseOption}
2   {-callv:compile_icl_commands}
```

Definitions

¶1. The preferred way to pass "do it this way, not that way" instructions to NI, in the spirit of natural-language input, is not to use command-line arguments in the shell but to write suitable sentences in the source text. For instance:

> Use American dialect and the serial comma.

Use options like "American dialect" take the place of what would be switches like `--american-dialect` in a conventional Unix tool. They are themselves defined by NI source (almost always the Standard Rules). They generally control run-time behaviour, and as a result NI deals with them simply by defining suitable I6 constants in the I6 code being output: conditional compilation of the standard I6 library then delivers the desired result. Anyway, the use options known to NI are stored in the following small structure.

Two use options are special: "memory economy" and "dynamic memory allocation". These can affect some of the run-time data generated by NI, and have effects which are not confined to conditional compilation at the I6 stage.

```
typedef struct use_option {
    int word_ref1, word_ref2;                    word range where name is stored
    struct parse_node *option_expansion;           definition as given in source
    int option_used;                             set if this option has been taken
    int source_file_scoped;                    scope is the current source file only?
    int minimum_setting_value;                     for those which are numeric
    MEMORY_MANAGEMENT
} use_option;

int memory_economy_in_force = FALSE;
int dynamic_memory_allocation = 0;
```

The structure use_option is private to this section.

¶2. We can also meddle with the I6 memory settings which will be used to finish compiling the story file, when NI has done its work. We need this because we have no practical way for NI to predict when it is going to generate code which will break I6's limits: the only reasonable way it can work is for the user to hit the limit occasionally, and then raise that limit by hand with a sentence in the I7 source text.

```
typedef struct i6_memory_setting {
    char ICL_identifier[64];                    see the DM4 for the I6 memory setting names
    int number;                                 e.g., 50000 means "at least 50,000"
    MEMORY_MANAGEMENT
} i6_memory_setting;
```

The structure i6_memory_setting is private to this section.

¶3. Inclusions are managed with the following modest structure.

```
typedef struct i6_inclusion_matter {
    struct parse_node *material_to_include;     normally an I6 escape (- ... -)
    struct world_object *wo_to_include_with;    or into an object or class definition
    MEMORY_MANAGEMENT
} i6_inclusion_matter;
```

The structure i6_inclusion_matter is private to this section.

---

§**1.** Inclusions are primitive things, but still a little more is involved than cut and paste.

```
sentence_handler INFORM6CODE_SH_handler =
    { INFORM6CODE_NT, -1, 2, inform_6_inclusion };

The function compile_icl_commands is invoked by a command in a `.i6t` template file.

11 Actions and Activities

`11/chron`: *Chronology.w* To parse representations of periods of time or of historical repetition, and to keep track of the state of things so that it will be possible in future to ask questions concerning the past.

`11/act`: *Actions.w* To define, map to I6 and index individual actions.

`11/anl`: *Action Name Lists.w* Action name lists provide a disjunction in the choice of action made by an action pattern. For instance, "taking or dropping the disc" results in a two-entry ANL. An empty ANL is also legal, and means "doing something" – the generic I7 text for "any action at all".

`11/ap`: *Action Patterns.w* An action pattern is a description which may match many actions or none. The text "doing something" matches every action, while "throwing something at a door in a dark room" is seldom matched. Here we parse such text into a data structure called an `action_pattern`.

`11/los`: *Looping Over Scope.w* To compile routines capable of being passed as arguments to the I6 library routine for looping over parser scope at run-time, and so to provide an implementation for conditions such as "in the presence of Mrs Dalloway".

`11/nap`: *Named Action Patterns.w* A named action pattern is a named categorisation of actions, such as "acting suspiciously", which is a disjunction of action patterns (stored in a linked list).

`11/ina`: *Actions Index.w* To construct the Actions index page.

`11/av`: *Activities.w* To create and manage activities, which are action-like bundles of rules controlling how the I6 runtime code carries out tasks such as "printing the name of something". Each has its own page in the I7 documentation. An activity list is a disjunction of actitivies.

Chronology 11/chron

Purpose

To parse representations of periods of time or of historical repetition, and to keep track of the state of things so that it will be possible in future to ask questions concerning the past.

11/chron.§2 Compiling chronology; §3-6 The periodic monitoring

Template interpreter commands

```
{-callv:allow_no_further_past_tenses}
{-callv:past_actions_i6_routines}
{-callv:past_tenses_i6_escape}
{-callv:chronology_extents_i6_escape}
```

Definitions

¶1. In two different contexts (action patterns and specifications) we will need a represention for periods of time. We measure time in two units: "times", as in something having been true four times in the past; and "turns", as in something having been true for five turns now. We will also need to keep track of four tenses when discussing time periods, and also whether we mean "three or more" (say) or "less than seven" turns or times. We represent this using the relevant I6 comparison operator: for instance a length of 5 and an operator `>=` denotes "five or more". Lastly, we can denote a closed interval of time as well, by setting `until` to the upper end.

```
define TIMES_UNIT 1                    used for "for the third time"
define TURNS_UNIT 2                    used for "for three turns"

define IS_TENSE 0                      Present
define WAS_TENSE 1                     Past
define HASBEEN_TENSE 2                 Present perfect
define HADBEEN_TENSE 3                 Past perfect

typedef struct time_period {
    int valid_tp;                      flag distinguishing validly and invalidly parsed periods
    int units;                         one of the two above
    int length;                        the duration or else the lower limit of an interval
    int until;                         -1 or else the upper limit of an interval
    char *inform6_operator;            <=, ==, >, and so forth
    int tense;                         one of the four above
} time_period;
```

The structure time_period is private to this section.

¶2. Some conditions stored in SPs, and also some actions stored in APs, are evaluated in the past tense, and to do this we need to lodge them into storage: the following simple structures are used for this.

```
typedef struct past_tense_condition_record {
    struct specification *condition;                    condition to be evaluated
    struct parse_node *where_ptc_tested;                sentence in which condition is found
    MEMORY_MANAGEMENT
} past_tense_condition_record;

typedef struct past_tense_action_record {
    struct action_pattern historic_action;              action pattern to be matched
    struct parse_node *where_pta_tested;                sentence in which AP is found
    MEMORY_MANAGEMENT
} past_tense_action_record;
```

The structure past_tense_condition_record is private to this section.

The structure past_tense_action_record is private to this section.

---

§**1.** This simple procedure looks at the text between `w1` and `w2` to look for an indication of a period of time, such as "twice" or "for more than the third time".

```

```

The function compile_past_action_pattern is called from 11/ap.
The function compile_past_tense_condition is called from 7/cosp.

§**3. The periodic monitoring.** As can be seen from the above routines, we depend on the array `TrackedActions`, on a routine called `TestSinglePastState` and on magical things happening at run-time at the start of every action. Once these are defined, it's too late to create any further past tense references, so:

```
void allow_no_further_past_tenses(void) {
    too_late_for_past_tenses = TRUE;
}
```

The function allow_no_further_past_tenses is invoked by a command in a `.i6t` template file.

§**4.** The `{-A}` ("past actions") escape. A series of `if` statements checking whether each past-tense action is now true, and updating the relevant array entries accordingly.

This looks straightforward, but a tricky point arises from the fact that a turn is not the same thing as a slot for an action. Usually they correspond, but not always. So if the action for a turn is taking, and that causes a further action of opening a box, say, what do we say about the number of turns for which the taking and opening actions have been happening?

In `adjust` mode, we are at the start or end of a "try" action which arises mid-turn. As can be seen, adjust mode is allowed only to change the record of how many turns an action has been happening – from 0 to 1, and otherwise making no change, if the action is the one being tried; or else back to 0 if it isn't. In particular, an action implicitly tried does not affect the "times" count.

This is a delicate business. The better way to solve this would be to stack a local copy of these arrays each time an action starts, and restore it (with updates) each time it finishes. But there is just no storage available in the Z-machine to contemplate this with equanimity, so we compromise. Historically, it's been a fertile source of tricky bugs. The test case `ActionInterrupted` should be checked if this code is ever tampered with.

```
void past_actions_i6_routines(OUTPUT_STREAM) {
    int once_only = TRUE;
    past_tense_action_record *pta;
    LOOP_OVER(pta, past_tense_action_record) {
        phsf_create_nonphrase_stack_frame();
        int pt = pta->allocation_id;
        current_sentence = pta->where_pta_tested;          ensure problems reported correctly
        WRITE("[ PAPR_%d;\n", pt); INDENT;
        WRITE("if (");
        ap_compile_forced_to_present(OUT, pta->historic_action);
        WRITE(") rtrue;\n");
        WRITE("rfalse;\n");
        OUTDENT; WRITE("];\n");
        if ((do_we_need_ct_locals()) && (once_only)) {
            once_only = FALSE;
            sentence_problem(_P_(C11PastTableLookup),
                "it's not safe to look up table entries in a way referring "
                "to past history",
                "because it leads to dangerous ambiguities. For instance, "
                "does 'taking an item listed in the Table of Treasure "
                "for the first time' mean that this is the first time taking "
                "any of the things in the table, or only the first time "
                "this one? And so on.");
```

```
        }
        phsf_remove_nonphrase_stack_frame();
    }
    WRITE("Array PastActionsI6Routines --> ");
    LOOP_OVER(pta, past_tense_action_record) {
        WRITE("PAPR_%d ", pta->allocation_id);
    }
    WRITE("0 0;\n");
}
```

The function past_actions_i6_routines is invoked by a command in a `.i6t` template file.

§**5.** The `{-C}` ("chronology") escape. The body of a switch statement in which the ith case results in the I6 variable `new` being set equal to the I6 condition stored up as past tense condition number i.

```
void past_tenses_i6_escape(OUTPUT_STREAM) {
    int once_only = TRUE;
    past_tense_condition_record *ptc;
    LOGIF(TIME_PERIODS,
        "Creating %d past tense conditions in TestSinglePastState\n",
            NUMBER_CREATED(past_tense_condition_record));
    phsf_create_nonphrase_stack_frame();
    phsf_determines_the_past();
    LOOP_OVER(ptc, past_tense_condition_record) {
        specification *spec = ptc->condition;

            ptc->allocation_id, spec_get_proposition(spec));
        WRITE("%d: new = ", ptc->allocation_id);
        current_sentence = ptc->where_ptc_tested;          ensure problems reported correctly
        if (prop_contains_callings(spec_get_proposition(spec))) {
            sentence_problem(_P_(C11PastCallings),
                "it's not safe to use '(called ...)' in a way referring "
                "to past history",
                "because this would make a temporary value to hold the "
                "quantity in question, but at a different time from when "
                "it would be needed.");
        }
        TEMPORARY_STREAM;
        spec_compile(TEMP, spec);
        STREAM_COPY(OUT, TEMP);
        CLOSE_TEMPORARY_STREAM;
        WRITE(";\n");
        if ((do_we_need_ct_locals()) && (once_only)) {
            once_only = FALSE;
            sentence_problem(_P_(C11PastTableEntries),
                "it's not safe to look up table entries in a way referring "
                "to past history",
                "because it leads to dangerous ambiguities. For instance, "
                "does 'taking an item listed in the Table of Treasure "
                "for the first time' mean that this is the first time taking "
                "any of the things in the table, or only the first time "
                "this one? And so on.");
        }
```

```
    }
    phsf_remove_nonphrase_stack_frame();
    LOGIF(TIME_PERIODS,
        "Creation of past tense conditions complete\n");
}
```

The function past_tenses_i6_escape is invoked by a command in a `.i6t` template file.

§**6.** The `{-E}` ("extents") escape. Sizes for the arrays. We need to do these after compiling the code in the escapes above, because they might continue to spawn each other as they compile: e.g. a past tense action pattern might itself refer to a condition in the still more remote past, as in the case of "After switching on the lunar clock when the lunar clock has been switched on for more than five times".

```
void chronology_extents_i6_escape(OUTPUT_STREAM) {
    WRITE("Constant NO_PAST_TENSE_CONDS %d;\n", no_past_tenses);
    WRITE("Constant NO_PAST_TENSE_ACTIONS %d;\n", no_past_actions);
}
```

The function chronology_extents_i6_escape is invoked by a command in a `.i6t` template file.

Actions 11/act

Purpose

To define, map to I6 and index individual actions.

Template interpreter commands

```
2   {-callv:Inform_name_the_actions}
6   {-array:ActionHappened}
10   {-callv:compile_action_routines}
11   {-array:ActionData}
11   {-array:ActionCoding}
```

Definitions

¶1. An action is an impulse to do something within the model world, and which may not be possible. Much of the work of designing an interactive fiction consists in responding to the actions of the player, sometimes in ways which the player expects, sometimes not. Design systems for interactive fiction therefore need to provide flexible and convenient ways to discuss actions.

An activity is by contrast something done by the run-time code during play: for instance, printing the name of an object, or asking a disambiguation question. These tasks must similarly be customisable by the designer, and a system of rulebooks is used which parallels the treatment of actions.

¶2. Some fields of this structure reflect the history of NI, and of I6 for that matter: in particular, very few actions if any now use an I6-library defined verb routine, but the ability is kept against future need; and the idea of a flexible number of parameters – which I6 allowed, thus parsing "listen" and "listen to the frog" as the same action, with 0 and 1 parameters respectively – has been dropped in I7. (We use the activities for selecting missing parameters instead.) So for now the minimum and maximum below are always equal.

```
typedef struct action_name {
    int word_ref1, word_ref2;                          such as "drop" or "take"
    int past_word_ref1, past_word_ref2;                such as "dropped" or "taken"
    int it_optional;                                   noun optional when describing the second noun?
    char an_I6_identifier[32];                         compile to this action name in I6
    int out_of_world;                                  action is declared as out of world?
    int censored;                                      from the index, due to bad language?
    int use_verb_routine_in_I6_library;                rather than compiling our own?
    struct rulebook *check_rules;                      rulebooks private to this action
    struct rulebook *carry_out_rules;
    struct rulebook *report_rules;
    struct stacked_variable_owner *owned_by_an;        action variables owned here
    struct parse_node *designers_specification;        where created
    int requires_light;                                does this action require light to be carried out?
    int min_parameters, max_parameters;                in the range 0 to 2
    int noun_access;                                   one of the possibilities below
```

```
    int second_access;
    struct kind_of_value *noun_kov;                    if there is at least 1 parameter
    struct kind_of_value *second_kov;                  if there are 2 parameters
    struct grammar_line *list_with_action;             list of grammar producing this
    int an_specification_text_word;                    description used in index
    int an_index_group;                                paragraph number it belongs to (1, 2, 3, ...)
    MEMORY_MANAGEMENT
} action_name;
stacked_variable_owner_list *all_nonempty_stacked_action_vars = NULL;
```

The structure action_name is shared with 11/ina.

¶3. The access possibilities for the noun and second noun are as follows.

```
define UNRESTRICTED_ACCESS 0                       question not meaningful, e.g. for a number
define IMPOSSIBLE_ACCESS 1                         action doesn't take a noun, so no question of access
define DOESNT_REQUIRE_ACCESS 2                     actor need not be able to touch this object
define REQUIRES_ACCESS 3                           actor must be able to touch this object
define REQUIRES_POSSESSION 4                       actor must be carrying this object
```

---

§**1.** The constructor function for action names divides them into two according to their implementation. Some actions are fully implemented in I6, and do not have the standard check/carry out/report rulebooks: others are full I7 actions. (As I7 has matured, more and more actions have moved from the first category to the second.)

```
action_name *act_new(int w1, int w2, int implemented_by_I7) {
    action_name *an;

The function act_check_types_for_grammar is called from 13/gl.

§**10. Compiling data about actions.** In I6, there was no common infrastructure for the implementation of actions: each defined its own `-Sub` routine. Here, we do have a common infrastructure, and we access it with a single call.

```
void compile_action_routines(OUTPUT_STREAM) {
    action_name *an;
    LOOP_OVER(an, action_name) {
        if (an->use_verb_routine_in_I6_library) continue;
        WRITE("[ %sSub; return GenericVerbSub(%d,%d,%d); ];\n",
            an->an_I6_identifier,
            an->check_rules->allocation_id,
            an->carry_out_rules->allocation_id,
            an->report_rules->allocation_id);
    }
}
```

The function compile_action_routines is invoked by a command in a `.i6t` template file.

§**11. Compiling data about actions.** There are also collective tables of data about actions.

```
void compile_ActionData_array(OUTPUT_STREAM) {
    action_name *an;
    int slots, mn, ms, ml, mnp, msp, hn, hs, j, j0, somethings;
    WRITE("Array ActionData table\n");
    LOOP_OVER(an, action_name) {
        if (an->use_verb_routine_in_I6_library) continue;
        mn = 0; ms = 0; ml = 0; mnp = 1; msp = 1; hn = 0; hs = 0;
        if (an->requires_light) ml = 1;
        if (an->noun_access == REQUIRES_ACCESS) mn = 1;
        if (an->second_access == REQUIRES_ACCESS) ms = 1;
        if (an->noun_access == REQUIRES_POSSESSION) { mn = 1; hn = 1; }
        if (an->second_access == REQUIRES_POSSESSION) { ms = 1; hs = 1; }
        if (an->noun_access == IMPOSSIBLE_ACCESS) mnp = 0;
        if (an->second_access == IMPOSSIBLE_ACCESS) msp = 0;
        WRITE("  ##%-32s  $$%d%d%d%d%d%d%d%d  ",
            an->an_I6_identifier,
            hs, hn,
            (an->out_of_world)?1:0, msp, mnp, ml, ms, mn);

The function act_index is called from 11/ina.

Action Name Lists 11/anl

Purpose

Action name lists provide a disjunction in the choice of action made by an action pattern. For instance, "taking or dropping the disc" results in a two-entry ANL. An empty ANL is also legal, and means "doing something" – the generic I7 text for "any action at all".

11/anl.§2 Specificity of ANLs

Definitions

```
typedef struct action_name_list {
    struct action_name *action_listed;                    the action in this ANL list entry
    struct action_name_list *next;                        next in this ANL list
    int word_position;                                    and some values used temporarily during parsing
    int parity;
    int parc;
    int parameter_w1[2], parameter_w2[2];
    int in_w1, in_w2;
    int abbreviation_level;                               number of words missing
    int anyone_specified;
} action_name_list;
```

The structure action_name_list is shared with 11/ap.

---

§**1.** The action name list is the part of an action pattern identifying which actions are allowed: "taking, dropping or examining" for example. The following routine extracts this from a potentially longer text (e.g. "taking, dropping or examining a door").

```
action_name_list *anl_new(void) {
    action_name_list *new_anl = CREATE(action_name_list);
    new_anl->action_listed = NULL;
    new_anl->parc = 0;
    new_anl->word_position = -1;
    new_anl->parity = 1;
    new_anl->in_w1 = -1;
    new_anl->in_w2 = -1;
    new_anl->abbreviation_level = 0;
    new_anl->anyone_specified = FALSE;
    return new_anl;
}

§**2. Specificity of ANLs.** The following is one of NI's standardised comparison routines, which takes a pair of objects A, B and returns 1 if A makes a more specific description than B, 0 if they seem equally specific, or −1 if B makes a more specific description than A. This is transitive, and intended to be used in sorting algorithms.

```
int compare_specificity_of_anl(action_name_list *anl1, action_name_list *anl2) {
    int count1, count2;
    count1 = count_actions_covered(anl1);
    count2 = count_actions_covered(anl2);
    if (count1 < count2) return 1;
    if (count1 > count2) return -1;
    return 0;
}
```

The function compare_specificity_of_anl is called from 11/ap.

Action Patterns 11/ap

Purpose

An action pattern is a description which may match many actions or none. The text "doing something" matches every action, while "throwing something at a door in a dark room" is seldom matched. Here we parse such text into a data structure called an `action_pattern`.

11/ap.§19-20 Action pattern specificity; §21-22 Compiling action patterns

Definitions

¶1. Action patterns are essentially a conjunction of specifications – the action must be this, *and* the noun must be that, *and*... While they allow disjunction in the choice of action, all of that code is a matter for the action name list to handle. The AP structure is a list of conditions all of which must apply at once.

One surprising point is that the AP is used not only for action patterns, but also in a slightly generalised role, as the condition for a rule to be applied. Most rules are indeed predicated on actions – "instead of eating the cake" – but some are instead in "parametrised" rulebooks, which means they apply to a parameter object instead of an action – "reaching inside the cabinet". These not-really-action APs are used in no other context, and employ the `parameter_spec` field below, ignoring the rest.

```
typedef struct action_pattern {
    int word_ref1, word_ref2;                          text giving rise to this AP
    struct named_action_pattern *named;                give a named action pattern...
    struct action_name_list *action;                   ...or give an ANL list (not both)
    int test_anl;                                      actually test the action when compiled
    int applies_to_any_actor;                          treat player and other people equally
    int request;                                       a request from the player for someone to do this?
    struct specification *actor_spec;
    struct specification *noun_spec;
    struct specification *second_spec;
    struct specification *presence_spec;               in the presence of...
    struct specification *room_spec;                   in...
    struct specification *when;                        when... (any condition here)
    struct specification *from_spec;                   for the "going" action only
    struct specification *to_spec;                     ditto
    struct specification *by_spec;                     ditto
    struct specification *through_spec;                ditto
    struct specification *pushing_spec;                ditto
    int nowhere_flag;                                  ditto: a flag for "going nowhere"
    struct ap_optional_clause *optional_clauses;
    int chief_action_owner_id;                         stacked variable ID number of main action
    struct time_period duration;                       to hold "for the third time", etc.
    struct specification *parameter_spec;              alternatively, just this
    int AP_parity;                                     +1 if meant positively, -1 if negatively
    int valid;                                         recording success or failure in parsing to an AP
    struct action_pattern *next;                       for forming APs into linked lists
} action_pattern;

typedef struct ap_optional_clause {
```

```
    struct stacked_variable *pertains_to;
    struct specification *clause_spec;
    struct ap_optional_clause *next;
    MEMORY_MANAGEMENT
} ap_optional_clause;
```

The structure action_pattern is private to this section.
The structure ap_optional_clause is private to this section.

¶2. When we parse action patterns, we record why they fail, in order to make it easier to produce helpful error messages. (We can't simply fire off errors at the time they occur, because text is often parsed in several contexts at once, so just because it fails this one does not mean it is wrong.) PAPF stands for "parse action pattern failure".

```
define MISC_PAPF 1
define NOPARTICIPLE_PAPF 2
define MIXEDNOUNS_PAPF 3
define WHEN_PAPF 4
define WHENOKAY_PAPF 5
define IMMISCIBLE_PAPF 6

int pap_failure_reason;                    one of the above
int permit_trying_omission = FALSE;        allow the keyword 'trying' to be omitted
```

```

This code is used in §6.

§**14.** We now have only the actual action left. First we see if it is a named pattern ("behaving suspiciously", say), rather than a match against an action's ordinary syntax ("taking something"):

⟨PAR - (h) Parse Named Action Pattern 14⟩ ≡

```
{ named_action_pattern *nap;
    int c1 = w1;
    int c2 = w2;
    j = is_the_word_in_intermediate(w1, w2);
    if (j>=0) { c2 = j-1; }
    if ((c1<=c2) && (nap = nap_by_name(c1, c2))) {
        ap.named = nap;
        ap.valid = TRUE;
        ap.when = wts;
        if (j>=0) {
            ap.room_spec = parse_action_parameter(j+1, w2, FALSE);
            if (validate_parameter(ap.room_spec, kova(OBJECT_TY)) == FALSE)
                ap.valid = FALSE;
        }
        if (ap.valid) goto Succeeded;
        goto Failed;
    }
}
```

This code is used in §6.

§**15.** Extract the information as to which actions are intended: e.g., from "taking or dropping something", that it will be taking or dropping.

⟨PAR - (i) Parse Initial Action Name List 15⟩ ≡

```
    anl = make_action_name_list(w1, w2, tense, 0, 1);
    if (anl == NULL) goto Failed;
    LOGIF(AP_PARSING, "ANL from PAR(i):\n$L\n", anl);
```

This code is used in §6.

§**16.** Now to fill in the gaps. At this point we have the action name list as a linked list of all possible lexical matches, but want to whittle it down to remove those which do not semantically make sense. For instance, "taking inventory" has two possible lexical matches: "taking inventory" with 0 parameters, or "taking" with 1 parameter "inventory", and we cannot judge without parsing the expression "inventory". The list passes muster if at least one match succeeds at the first word position represented in the list, which is to say the last one lexically, since the list is reverse-ordered. (This is so that "taking or dropping something" requires only "dropping" to have its objects specified; "taking", of course, does not.) We delete all entries in the list at this crucial word position except for the one matched.

⟨PAR - (j) Parse Parameters 16⟩ ≡

```
{ action_name_list *anl_link = anl;
    int first_word_represented = anl->word_position;
    int no_positions = 0, position_at[100], position_min_parc[100],
        positions_with_min_parc[3];
    while (anl_link != NULL) {
        int i, j=-1;
        for (i=0; i<no_positions; i++)
            if (anl_link->word_position == position_at[i])
                j = i;
        if (j == -1) {
            if (no_positions == 100) goto Failed;
            position_at[no_positions] = anl_link->word_position;
            position_min_parc[no_positions] = 1000000;
            j = no_positions++;
        }
        if (anl_link->parc < position_min_parc[j])
            position_min_parc[j] = anl_link->parc;
        anl_link = anl_link->next;
    }
    for (i=0; i<3; i++) positions_with_min_parc[i] = 0;
    for (i=0; i<no_positions; i++) {
        LOGIF(AP_PARSING, "ANL position %d (word %d): min parc %d\n",
            i, position_at[i], position_min_parc[i]);
        if ((position_min_parc[i] >= 0) && (position_min_parc[i] < 3))
            positions_with_min_parc[position_min_parc[i]]++;
    }

                anl_link = anl_link->next;
            }
            goto ParameterListMade;
        }
        anl_link = anl_link->next;
    }
    goto Failed;
    ParameterListMade: ;
}
```

This code is used in §6.

§**17.** Not all actions can cohabit. We require that as far as the user has specified the parameters, the actions in the list must all agree (i) to be allowed to have such a parameter, and (ii) to be allowed to have a parameter of the same type. Thus "waiting or taking something" fails (waiting takes 0 parameters, but we specified one), and so would "painting or taking something" if painting had to be followed by a colour, say. Note that the "doing anything" action is always allowed a parameter (this is the case when the first action name in the list is `NULL`).

⟨PAR - (k) Verify Mixed Action 17⟩ ≡

```
{ action_name_list *anl_link = anl;
    int nnz = 0;
    if (anl->action_listed == NULL) {
        if (anl->parc >= 2) goto Failed;
        goto Succeeded;
    }
    while (anl_link != NULL) {
        if ((anl_link->action_listed != NULL) &&
            (act_get_max_parameters(anl_link->action_listed) < anl->parc)) {

The function ap_count_aspects is called from 12/phrcd.
The function compare_specificity_of_ap is called from 12/phrcd.

§**20.** And an anticlimactic little routine for putting objects into action patterns in the noun or second noun position.

```
void put_action_object_into_ap(action_pattern *ap, int pos,
    int w1, int w2) {
    specification *spec = parse_expression(w1, w2, TYPE_OR_VALUE_EXPCON);
    if ((spec_is_CONSTANT_of_kova(spec, TEXT_TY)) ||
        (spec_is_CONSTANT_of_kova(spec, TEXT_ROUTINE_TY)))
        spec_set_kind_of_value(spec, kova(UNDERSTANDING_TY));
    spec->word_ref1 = w1; spec->word_ref2 = w2;
    LOGIF(AP_PARSING, "PAOIA (position %d) $W = $S\n", pos, w1, w2, spec);
    switch(pos) {
        case 1: ap->noun_spec = spec; break;
        case 2: ap->second_spec = spec; break;
        case 3: ap->room_spec = spec; break;
    }
}
```

§**21. Compiling action patterns.** In the following routines, we compile a single clause in what may be a complex condition which determines whether a rule should fire. The flag `f` indicates whether any condition has already been printed, and is updated as the return value of the routine. (Thus, it's permissible for the routines to compile nothing and return `f` unchanged.) The simple case first:

```
int CAP_insert_clause(int f, OUTPUT_STREAM, char *i6_condition) {
    if (f) WRITE(" && ");
    WRITE("(%s)", i6_condition);
    return TRUE;
}
```

§**22.** The more complex clauses mostly act on a single I6 global variable. In almost all cases, this falls through to the standard method for testing a condition: we force it to propositional form, substituting the global in for the value of free variable 0. However, rule clauses are allowed a few syntaxes not permitted to ordinary conditions, and these are handled as exceptional cases first:

(a) A table reference such as "a Queen listed in the Table of Monarchs" expands.

(b) Writing "from R", where R is a region, tests if the room being gone from is in R, not if it is equal to R. Similarly for other room-related clauses such as "through" and "in".

(c) Given a piece of run-time parser grammar, we compile a test against the standard I6 topic variables: there are two of these, so this is the exceptional case where the clause doesn't act on a single I6 global, and in this case we therefore ignore `I6_global_name`.

```
int CAP_match_clause(int f, OUTPUT_STREAM, quantity *I6_global_quantity,
    specification *spec, int verify_as_description_of_object) {
    specification *I6_var_TS;
    int force_proposition = FALSE;
    if (spec == NULL) return f;

Looping Over Scope 11/los

Purpose

To compile routines capable of being passed as arguments to the I6 library routine for looping over parser scope at run-time, and so to provide an implementation for conditions such as "in the presence of Mrs Dalloway".

Template interpreter commands

```
0   {-callv:compile_los_routines}
```

Definitions

```
typedef struct loop_over_scope {
    struct specification *what_to_find;
    MEMORY_MANAGEMENT
} loop_over_scope;
```

The structure loop_over_scope is private to this section.

```
loop_over_scope *los_new(specification *what) {
    loop_over_scope *los = CREATE(loop_over_scope);
    los->what_to_find = spec_copy_and_copy_docket(what);
    spec_clear_calling(los->what_to_find);
    return los;
}
void compile_los_routines(OUTPUT_STREAM) {
    loop_over_scope *los;
    LOOP_OVER(los, loop_over_scope) {
        ph_stack_frame *phsf = phsf_create_nonphrase_stack_frame();
        phsf_add_it_variable(phsf, -1, -1, kova(OBJECT_TY));
        OUT = begin_compiling_phrase(OUT);
        begin_code_blocks();

        WRITE("if (");
        CAP_match_clause(FALSE, OUT, qty_temporary_quantity("t_0"),
            los->what_to_find, TRUE);
        WRITE(") los_rv = t_0;\n");
        OUTDENT; WRITE("];\n");
        OUT = write_routine_header();
        WRITE("[ LOS_%d ", los->allocation_id);
        copy_compiled_phrase();
        end_code_blocks();
        phsf_remove_nonphrase_stack_frame();
    }
}
```

The function los_new is called from 11/ap.

The function compile_los_routines is invoked by a command in a `.i6t` template file.

Named Action Patterns 11/nap

Purpose

A named action pattern is a named categorisation of actions, such as "acting suspiciously", which is a disjunction of action patterns (stored in a linked list).

Template interpreter commands

```
0   {-callv:compile_named_action_patterns}
```

Definitions

```
typedef struct named_action_pattern {
    struct action_pattern *first;                    list of APs defining this NAP
    int word_ref1, word_ref2;                        text of declaration
    char nap_I6_identifier[32];                      for an I6 routine to test this NAP
    MEMORY_MANAGEMENT
} named_action_pattern;

Actions Index 11/ina

Purpose

To construct the Actions index page.

Template interpreter commands

```
4   {-callv:index_page_Actions}
```

Definitions

¶1. The following modest structure is used for the indexing of command verbs, and is too deeply boring to comment upon. These are the headwords of commands which can be typed at run-time, like QUIT or INVENTORY. For indexing purposes, we divide these headwords into five "natures":

```
define NORMAL_COMMAND 1
define ALIAS_COMMAND 2
define OUT_OF_WORLD_COMMAND 3
define TESTING_COMMAND 4
define BARE_DIRECTION_COMMAND 5

typedef struct command_index_entry {
    int nature;                                              one of the above values
    char *command_headword;                  text of command headword, such as "REMOVE"
    struct grammar_verb *gv_indexed;                                    ...leading to...
    struct command_index_entry *next_alphabetically;                    next in linked list
    MEMORY_MANAGEMENT
} command_index_entry;

command_index_entry *sorted_command_index = NULL;                  in alphabetical order of text
```

The structure command_index_entry is private to this section.

```
void index_meta_verb(char *t) {
    command_index_entry *vie;
    vie = CREATE(command_index_entry);
    vie->command_headword = t;
    vie->nature = OUT_OF_WORLD_COMMAND;
    vie->gv_indexed = NULL;
    vie->next_alphabetically = NULL;
}

void index_test_verb(char *t) {
    command_index_entry *vie;
    vie = CREATE(command_index_entry);
    vie->command_headword = t;
    vie->nature = TESTING_COMMAND;
    vie->gv_indexed = NULL;
    vie->next_alphabetically = NULL;
}

void index_verb_definition(char *p, char *trueverb) {
    int i = 1;
    if ((p[0] == 0) || (p[1] == 0)) return;
    if (trueverb) {
```

    }
}
```

The function index_page_Actions is invoked by a command in a `.i6t` template file.

Activities 11/av

Purpose

To create and manage activities, which are action-like bundles of rules controlling how the I6 runtime code carries out tasks such as "printing the name of something". Each has its own page in the I7 documentation. An activity list is a disjunction of actitivies.

11/av.§1 Activity variables; §2-3 Activity indexing

Template interpreter commands

```
1   {-array:activity_var_creators}
2   {-callv:compile_activity_constants}
2   {-array:Activity_before_rulebooks}
2   {-array:Activity_for_rulebooks}
2   {-array:Activity_after_rulebooks}
2   {-array:Activity_atb_rulebooks}
```

Definitions

```

12 Phrases and Rules

`12/iphr`: *Introduction to Phrases.w* An exposition of the data structures used inside Inform to hold phrases, rules and rulebooks.

`12/cs`: *Construction Sequence.w* To deal with all the `.i6t` interpreted commands which bring about the compilation of phrases, and to ensure that they are used in the correct order.

`12/ph`: *Phrases.w* To create one `phrase` object for each phrase declaration in the source text.

`12/phud`: *Phrase Usage.w* To parse the preamble of a phrase declaration to a `ph_usage_data` (PHUD) structure containing a still mostly textual representation of the conditions for its usage; to issue problem messages diagnosing bad syntax in these preambles; later, to parse further in order to convert the PHUD to a no longer textual PHRCD structure; finally, to use a PHUD to create a suitable primary booked rule (BR) for any phrase destined to be a rule, employing any predeclared BR for the phrase which may exist.

`12/phrcd`: *Phrase Runtime Context Data.w* To create, logically compare the specificity of, and compile I6 tests which check the current validity of, the circumstances in which a rule phrase should be used. All interesting PHRCD structures are manufactured from PHUDs, however, and the code for that is found in the Phrase Usage section.

`12/phtd`: *Phrase Type Data.w* To create, manage, compare the logical specificity of, and assist excerpt parsing concerning, the type of a To phrase. This involves whether it is void, determines a condition or returns a value (and if so, what kind of value); and also what parameters it takes (possibly values, possible other types used by inline definitions) and their types in turn.

`12/phod`: *Phrase Options.w* To create and subsequently parse against the list of phrase options with which the user can choose to invoke a To phrase.

`12/phsf`: *Stack Frames.w* To create, and parse local value names within the context of, stack frames. A stack frame is a context in which sequences of void-phrase expression evaluations can be performed, that is, in which procedural code can be compiled. Each phrase compiled to an I6 routine needs such a context, but a stack frame can also arise when other routines not derived from phrases are being compiled. In this section we also manage the beginning and ending of code blocks (as in "If ... begin; ...; end if").

`12/stv`: *Stacked Variables.w* To permit quantities to belong to rulebooks, and to have limited name-scope.

`12/cinv`: *Compile Invocations.w* Here we generate Inform 6 code to execute the phrase(s) called for by an invocation list.

`12/ambig`: *Runtime Ambiguities.w* To keep track of runtime ambiguities likely to arise, classifying them into equivalent questions, in order to minimise the amount of run-time checking code which will be needed.

`12/cph`: *Compile Phrases.w* For each phrase whose declaration involves a list of expressions to be evaluated in void context – that is, whose declaration is not an inline piece of I6 – we compile a suitable I6 routine. We also provide some utilities for other sections of NI needing to compile I6 routines not derived directly from phrases.

`12/toph`: *To Phrases.w* The first of four ways phrases are invoked: in the definitions of other phrases, and in I7 expressions and conditions. Here a phrase is used much as a function would be used in a C-like language.

`12/phin`: *Phrasebook Index.w* To compile the HTML page for the Phrasebook index.

`12/def`: *Adjectival Definitions.w* The second of four ways phrases are invoked: as definitions of adjectives which can be used as unary predicates in the calculus. (And we also look after adjectives arising from I6 or I7 conditions, and from I6 routines.)

`12/tiph`: *Timed Phrases.w* The third of four ways phrases are invoked: as timed events, which need no special NI data structure and are simply compiled into a pair of timetable I6 arrays to be processed at run-time.

`12/br`: *Rules.w* The fourth of four ways phrases are invoked: as rules capable of being placed in rulebooks. Each such phrase is pointed to by one or more `booked_rule` structures, which are analogous to looseleaf pages for use in ring-binders: a page can either be left looseleaf, or can be bound into a single rulebook. NI requires that phrases be able to belong to multiple rulebooks, and this is achieved by creating a different BR for each such membership. Here we create and manage both individual BRs and linked lists of BRs in logical specificity order.

`12/rb`: *Rulebooks.w* To create, manage, compile and index rulebooks, the content of which is a linked list of booked rules together with some general conventions as to how they are to be used.

`12/rps`: *Rule Placement Sentences.w* To parse and act upon explicit sentences like "The fire alarm rule is listed after the burglar alarm rule in the House Security rules."

Introduction to Phrases 12/iphr

Purpose

An exposition of the data structures used inside Inform to hold phrases, rules and rulebooks.

§**1.** Much of the typical source text for an Inform work of IF consists of phrase declarations, consisting of a preamble, then a colon (except in a few cases where commas are permitted) and then a list of phrase invocations divided by semicolons. Some declarations ("To..." phrases) declare what most Inform writers think of as phrases; some define adjectives ("Definition: ..."); others declare "rules" ("Instead of jumping..."). Grammatically, every phrase is a single sentence, even when quite long and written out in a tabulated, computer language sort of form: rather as Philip Larkin's poem *MCMIV* is a single sentence through all four stanzas.

Internally, these forms are handled by largely common code and data structures with as much commonality between them as possible.

§**2. Phrases are not invocations.** In common with Inform 7 documentation generally, NI uses the word "phrase" in a more specialised way than the usual English sense of "a small group of words standing together as a conceptual unit, typically forming a component of a clause".

NI uses the term "excerpt" for this, reserving "phrase" for a more specific meaning, or rather for three related ones:

(1a) One of the possible forms of instruction to do something or to decide something, generally defined by text such as "To award (N - a number) points: ...".

(1b) One of the rules, defined by text such as "Before eating the cake, ...".

(2) An actual instruction to do something, such as "award 50 points". These are properly speaking "invocations" of phrases rather than phrases themselves, and are – as we have seen – stored in the references list of `PHRASE` specifications during type-checking and code generation.

The `phrase` structure holds details of each possible form (1a) or (1b). Each of these is defined *either* as a list of invocations (2) of phrases (1a) to do something, in which case the definition will be compiled as an I6 routine, *or* as an I6 schema. Here are examples of these two forms of definition, both for phrases (1a) to do something:

```
To spring the trap: say "Sproing!"; move the player to the Cage.
```

```
To award (some - number) points: (- score=score+some; -).
```

When we compile an invocation (2) of these, "spring the trap" is compiled to an I6 function call to the definition routine, which might typically look like `R_231();`, whereas "award 50 points" is compiled inline to `score=score+50;`.

A phrase (1b) might be defined using I7 source like so:

```
A reaching inside rule for the flask: allow access.
```

These phrases have no invocations, and often no names: they simply take effect when needed. Their definitions are always as I6 routines.

§**3. Data structures for phrase declarations.**

Each declaration corresponds to a `phrase` structure. This is an anthology of five sub-structures for different purposes: PHUD, PHTD, PHSF, PHRCD and PHOD. The data in these structures is used to represent the information in the preamble, and also information needed during compilation of the body of the declaration (local variable names which come and go, for instance).

Further structures represent individual local variables (`local_variable`) within PHSFs, and individual phrase options (`phrase_option`) within PHODs.

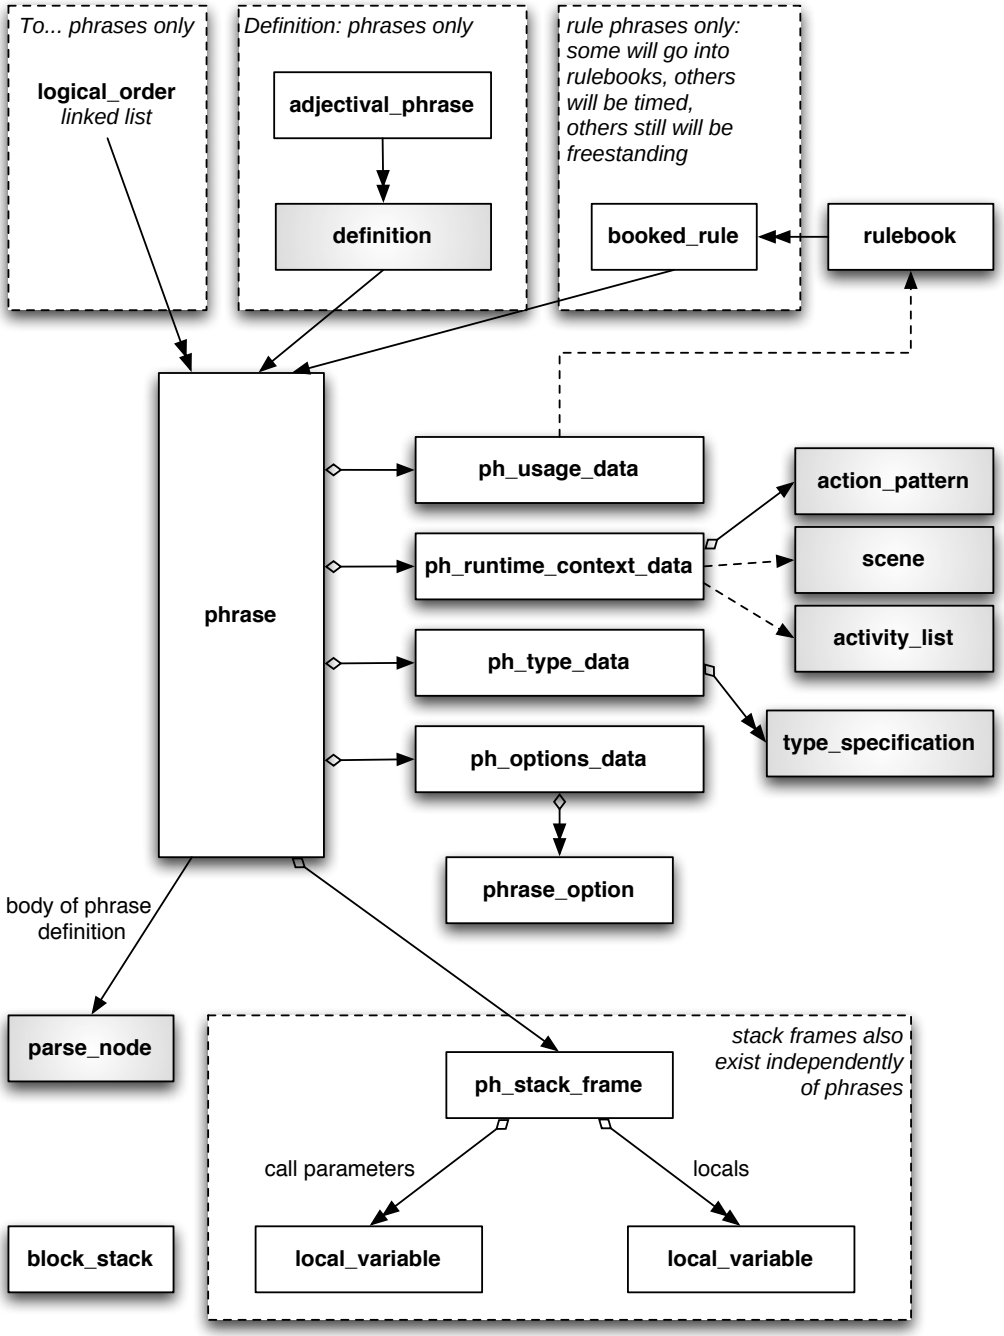
Whereas "To..." phrases compile to I6 routines which are called as necessary from I6 expressions explicitly compiled by I7, rules are placed into I6 arrays and are invoked at the whim of the I6 run-time code. There are two main sets of arrays: the timetable arrays, used for rules whose usage is quoted in terms of time ("At 10:23 AM: ..."), and rulebooks, used for rules quoted as applying to actions, activities or similar. In both cases, a small structure called a `booked_rule` is used to represent an individual booking within the timetable or a rulebook: this is analogous to a page on which a rule is written. BRs need to exist because the same rule can be written into more than one rulebook; there is only one phrase structure for the rule, but a different BR for each place where it is used.

NI does not use a structure to represent the timetable, but simply generates it when needed. Rulebooks, however, are stored as `rulebook` structures.

Finally, we also use booked rules to provide definitions of adjectives. Each individually named adjective has an `adjectival_phrase` structure.

None of the routines in this chapter is especially complex, but the situation is complicated by (a) the large number of varied structures being dealt with and (b) some awkward timing constraints which cause these structures to be built and used in unobvious sequences. To cope with this, the code for the substructures is

encapsulated so far as is possible, and the first section of the chapter centralises all of the timing contraints into one place, documented the sequence which is needed.



§**4. The five phrase substructures.** To recap, a `phrase` is internally divided into five substructures, whose names are abbreviated as PHUD, PHTD, PHSF, PHRCD and PHOD.

(i) The phrase usage data (PHUD) contains the results of parsing the preamble of the declaration to see what kind of phrase is to be created. For "To..." phrases, little is recorded. For rules, the PHUD contains all the information needed to place the rule within its rulebook.

(ii) Conversely, the phrase type data (PHTD) is primarily useful for "to..." phrases. It records the pattern of text to be registered as an excerpt with the excerpt parser, and the types required for the tokens in the definition.

Because they are registered directly with the excerpt parser, "To..." phrases are not placed in any rulebook or stored in any run-time array. But the order in which they are registered is important, because the excerpt parser returns the first match it can, so that it is important that more specific phrases are stored before less specific ones. The judgement on specificity of a phrase is made on its PHTD alone.

(iii) The phrase options data (PHOD) contains the names of phrase options, if any apply, and whether or not they are mutually exclusive. It is used only for "To..." phrases, and is separated from the PHTD because it is parsed separately from the excerpt parser mechanism and because it is not used in type-checking.

(iv) The phrase run-time context data (PHRCD) contains data structures which store the fully-parsed preamble. This is of use only with rules, and contains (for instance) the parameter to be used when placing the rule into its rulebook – an action pattern structure. When such phrases are created, they are bound up into "booked rules" (see below) and these BRs are placed into rulebooks. Rules in rulebooks are sorted into order of specificity, and this judgement is made on the contents of the PHRCD alone.

(v) The phrase stack frame (PHSF) contains the local named values valid in a given compilation context. (Names of phrase options can also be used locally and for this the PHOD is used, but they are used as conditions not values.) These named values include local variables, which are added during compilation of the phrase, but also the call parameters of the phrase, which are generated from the tokens recorded in the PHTD. The PHSF is not necessarily empty for rules, because rule preambles sometimes contain "callings": "Instead of taking a container (called the bag): ..." requires a PHSF which contains "bag" as a locally named value, for instance.

Uniquely of the five substructures of `phrase`, the PHSF can exist independently of any `phrase` structure in more than a temporary way. Free-standing PHSF stack frames are used when compiling text which contains substitutions, and for other code-compilation purposes where code does not arise explicitly from phrase declarations in the source.

To sum up, a "to..." phrase makes use of a PHUD (minimally), a PHTD (for sorting, registration and type-checking), a PHOD, and a PHSF. A rule phrase makes use of a PHUD (more heavily), a PHRCD (for sorting and to compile checks on applicability), and a PHSF.

The obvious simplification in this scheme would be to include the PHRCD within the PHUD, and the PHOD within the PHTD, thus reducing the picture to just three structures. We do not do this because there are significant timing difficulties.

Construction Sequence 12/cs

Purpose

To deal with all the `.i6t` interpreted commands which bring about the compilation of phrases, and to ensure that they are used in the correct order.

10   {-callv:compile_rulebooks}
10   {-array:RulebookNames}
10   {-callv:compile_rule_printing_switch}
```

---

§**1. Timing issues.** Suppose we compare the run of NI to a single day. At dawn the program starts up, initialises the memory manager, opens the debugging and problem logs, etc. In mid-morning it runs through the assertion sentences twice, acting to create the world objects and their properties, the rulebooks, the named global variables and so forth. It then completes work with the initial state of things, constructing its world model. By noon, a decisive change is reached: it is now possible to parse non-constant expressions, which require the use of phrases to evaluate them. In the afternoon, the phrase declarations are compiled into I6 routines, and in the late afternoon the grammar is put together, text with substitution routines are compiled, and so forth. At nightfall, NI completes its run.

However, work on phrases is not left entirely until the afternoon. In the early morning, we run through the phrase preambles to look for named rules. (For instance, a phrase like "Instead of pushing the red button (this is the fire alarm rule): ...") This looking-for-names is done by parsing the preamble text to a PHUD in what is called "coarse mode", which can only get an approximate idea of the contents; it is so early in the morning that more sophisticated parsing is not possible, because so many named values do not exist yet. The PHUD thus produced is immediately thrown away once we have our answer; there is in any case no `phrase` structure yet to which it could be attached.

For each rule name which is found (here "the fire alarm rule"), an empty "booked rule" structure is created. Booked rules are analogous to pages in a rulebook; just as the same idea might be written onto pages in different books, the same phrase can appear in more than one booked rule. No rulebooks will exist until mid-morning, so at this stage any booked rules created will just be looseleaf pages, and since no phrases will exist until they afternoon, they will also be blank; but we can imagine them containing a Post-It reading "put phrase X here once it is created". The name is then registered as an excerpt whose data points to this booked rule. This needs to be done because the rule name is a value which might be used as a property of

an object, or the initial state of a global variable, or an entry in a Table; and therefore the name has to be registered before the mid-morning run through the assertions. Such a booked rule is said to be "predeclared".

Rulebooks, unlike rules, are created with standard assertion sentences, just like objects. ("When play begins is a rulebook.") They therefore appear during the mid-morning run, and their names are registered immediately. Rulebooks are like ring-binders, and they are created empty of pages.

In the late morning, all objects, kinds, rulebooks, variables, rules, etc., have their names. Because rulebook names in particular exist, we can get further in parsing the preambles to phrase declarations. So NI now runs through the preambles again and parses them for a second time to PHUDs, but this time in "fine mode" rather than "coarse mode", and this time the result is not thrown away. If the phrase is a "To..." phrase declaration, then the PHUD was pretty sketchy and we parse more substantial PHTD and PHOD structures to accompany it. If it is a rule, the PHUD contains a great deal of useful information, and we accompany it with essentially blank PHTD and PHOD structures. Either way, we have now assembled a PHUD, PHTD and PHOD: these are combined into a new `phrase` structure. The PHSF structure is initially created as a function of the PHTD, converting the token names (if there are any) to call parameter local variables. A blank PHRCD structure is created to fill out the set of five substructures.

As they are created, the "To..." phrases are insertion-sorted into a list of phrases in logical precedence order. Phrases which are destined to be adjective definitions are similarly insertion-sorted into the list of meanings for the relevant adjective, again in logical precedence order. (This can be done now because it relies only on names of kinds and types, all of which have existed since mid-morning.)

As phrases destined to be rules are created, they are each given a "primary booking" by being copied onto a new blank rulebook page. If a predeclared BR for the phrase already exist, then that one is used (we remove the metaphorical Post-It note and write in the metaphorical text of the phrase); if not, we create a new booked rule structure for the phrase. Either way, at this point every rule-like phrase now has one and only one booked rule structure in existence with the phrase written on it.

It is now nearly noon, and things appear to be a little untidy. Why are the "To..." phrases not yet registered with the excerpt parser? Why are the rules all over the floor on single pages, while the ring-binder rulebooks still lie empty? The answer in both cases is that we needed to wait until all of the "To..." phrases had been created as structures before we could safely proceed. The first phrase cannot be registered until we know the complete logical order of the phrases. With rules, the problem is worse: these cannot even be sorted yet, since they are sorted by their PHRCDs, and unlike the PHTDs a PHRCD cannot even be parsed until all the phrases have been registered – a rule might have been specified to happen "when in darkness", say, requiring that NI recognise the text "in darkness" as the name of a phrase.

So, with the clock approaching noon, we finally have the "To..." phrases sorted into logical order. We at last register these in sequence, and just as this is done, the hour chimes. From this point onwards, arbitrary run-time expressions can be parsed by NI, and there are no longer any names-which-do-not-exist-yet problems.

In the afternoon, we begin by binding up the rulebooks. First, we go through the phrases destined to be rules, and for each we translate the PHUD (which contains mainly textual representations of the usage information, e.g. "taking something (called the thingummy) which is in a lighted room during Scene Two when the marble slab is open") to a PHRCD (which contains fully parsed NI data structures, e.g., an action pattern and a pointer to a `scene` structure). This PHUD-to-PHRCD parsing is at last possible, since it is afternoon. During the PHUD-to-PHRCD parsing process, we make sure that the relevant phrase's PHSF is the current stack frame, because it's here that the names of any callings (e.g. "thingummy") are created as local variables to be valid throughout the phrase. The PHUD will never be used again.

Second, we go through the rules once again. Every rule-phrase has a BR (booked rule) structure, which is like a looseleaf rulebook page with the phrase written on it. In some cases (such as "Instead of taking something: ...") the preamble indicates a rulebook for which it is destined (here "instead"), but other rule preambles indicate no specific rulebook (as in "The fire alarm rule: ..."). Where we do have a rulebook in mind, we add the BR to the rulebook, insertion sorting it into logical precedence order as deduced from the PHRCD.

It might seem as if the rulebooks are now complete, but this is not true, because we still have to deal with any assertion sentences requiring particular named rules to be placed in particular positions in rulebooks. We do that now, creating new BRs as required.

It is now mid-afternoon, and the rulebooks are complete. It is time to compile the I6 routines which will provide the run-time definitions of all these phrases. First we compile the "To..." phrases, except that we omit phrases defined inline with an explicit I6 escape; these do not compile to I6 function calls, so they need no I6 functions as their definitions. A "To..." phrase is compiled using only the PHSF, the current stack frame: the other substructures are no longer needed.

Secondly we compile the rules. We do this in rulebook order simply to make the I6 code easier to read: it makes no difference otherwise. But we need to remember that there are still rule phrases which are looseleaf, that is, whose booked rules are not found in any rulebook. So we need to finish up by compiling rule routines for rules not in any rulebook. A rule phrase is compiled using both the PHSF, as the current stack frame, and also the PHRCD, which is used to compile the applicability test for the rule. (For instance, for "Instead of jumping during Scene V", the test would be that the action is jumping and that Scene V is currently under way.) The other substructures are no longer needed.

This is a long process, and stretches on until evening. We have four final tasks: to compile the I6 arrays which describe the rulebook contents; to compile a timetable array for those looseleaf rules which specified their usage as times ("At 3:15 PM: ...") or as events ("When the alarm clock goes off: ..."); to reconcile the names of predeclared BRs; and to compile I6 routines for the unary predicates representing adjectives at run-time, which will mean using the BRs assigned as definitions to adjectives.

The reconciliation needs some explanation. Suppose back in early morning we predeclared a BR under the name of the "fire alarm rule". An I6 constant may have been needed during the mid-morning which evaluated to the I6 routine for this phrase. But of course that phrase's I6 routine name could not have been known then, because the phrase did not exist until late morning. We get around this by creating a constant in the form `BR_1`, `BR_2`, etc., in early morning, and then compiling I6 constant declarations in the evening which define these constants in terms of the I6 routines they are now known to have represented: thus `Constant BR_1 = R_321;`, for instance.

And at last the sun slips below the horizon. As it does so, note that in spite of all our efforts in the evening, there may still be a few looseleaf rules in existence: rules which were never written into any rulebook, or into the timetable, or used to define anything. This is not necessarily a mistake – sometimes rules are defined which the user intends to dynamically assign to rulebooks at run-time, and which have no rulebook assignment at compile time.

§2. Summary of time sequence.

Dawn. NI starts up.

Early morning. Looseleaf, blank booked rules are made for any named rules, and names registered for them.

Mid-morning. NI works through the assertion sentences, creating and naming the world, and in particular creating and naming rulebooks. These are initially empty.

Late morning. The phrase structures are created. "To..." phrases are sorted into logical precedence order. Rule phrases have booked rules made for them, unless they already have one from early morning: however, their conditions of use remain as largely unparsed data in PHUDs.

Just before noon. The "To..." phrases are registered, in logical precedence order.

Noon. NI passes a significant milestone: before this point, only constant expressions could be parsed, but from now on, any expression can be parsed, including one which makes use of the "To..." phrases.

Early afternoon. The rule phrases have their PHUDs parsed into PHRCDs. Any rule phrase whose preamble specifies a rulebook is logically sorted into that rulebook. The explicit sentences in the source which describe how rules should occur in rulebooks are then obeyed, and the rulebooks are finally completed.

Mid-afternoon. The bodies of phrase declarations are compiled into suitable I6 routines.

Evening. The arrays giving the run-time form of rulebooks and of the event timetable are compiled, and constants are created which enable names of routines not compiled until afternoon to have been used as constants in the morning. Definitions of adjectives are compiled.

Nightfall. NI shuts down.

§**3.** To make sure that none of this happens out of sequence, we take the following precautions. (It isn't as unlikely that this might occur as it may seem – the timing is actually controlled by the sequence of calls in the interpreted `Main.i6t` file, which hackers might try to alter.)

```
define DAWN_PHT 0
define EARLY_MORNING_PHT 1
define MID_MORNING_PHT 2
define LATE_MORNING_PHT 3
define PRE_NOON_PHT 4
define NOON_PHT 5
define EARLY_AFTERNOON_PHT 6
define MID_AFTERNOON_PHT 7
define EVENING_PHT 8
define NIGHTFALL_PHT 9

int phrase_time_now = DAWN_PHT;

void advance_phrase_time_to(int advance_to) {
    if (advance_to < phrase_time_now) {
        LOG("Advance to: %d   Time now: %d\n", advance_to, phrase_time_now);
        internal_error(
            "The necessary phrase construction events are out of sequence");
    }
    phrase_time_now = advance_to;
}
```

§4. Early morning.

```
void traverse_for_phrase_names(void) {
    parse_node *p;
    advance_phrase_time_to(EARLY_MORNING_PHT);
    for (TREE_START(p); p; TREE_NEXT(p))
        if (pn_get_node_type(p) == ROUTINE_NT)
            phud_predeclare_name_in(p);
}
```

The function traverse_for_phrase_names is invoked by a command in a `.i6t` template file.

§**5. Mid-morning.** This is when NI is making its main traverses through assertions. We will ignore all commands (i.e., lines in the body of phrase declarations) and phrase preambles, so we give them null handlers. On the other hand, we do indeed want to act on declarations of I6 library rules: that is, sentences like "The can't act in the dark rule translates into I6 as `"CANT_ACT_IN_THE_DARK_R"`.", which cause a booked rule to be created which corresponds not to a `phrase` structure but to an already-compiled `I6` routine.

```
sentence_handler COMMAND_SH_handler = { COMMAND_NT, -1, 0, NULL };
sentence_handler ROUTINE_SH_handler = { ROUTINE_NT, -1, 0, NULL };

void handle_library_rule(parse_node *p) {
    new_br_from_i6(p->down->next->word_ref1, p->down->next->word_ref2,
        p->down->next->next->word_ref1, FALSE);
}
```

The function handle_library_rule is called from 2/isn.

§6. Late morning.

```
void traverse_for_phrases(void) {
    parse_node *p;
    int progress_target = 0, progress_made = 0;
    advance_phrase_time_to(LATE_MORNING_PHT);
    for (TREE_START(p); p; TREE_NEXT(p)) progress_target++;
    for (TREE_START(p); p; TREE_NEXT(p)) {
        progress_made++;
        if (progress_made % 10 == 0)
            progress_bar(3, ((float) progress_made)/((float) progress_target));
        if (pn_get_node_type(p) == ROUTINE_NT) {
            ph_create_from_preamble(p);
            finish_this_session_of_parsing();
        }
    }
}
```

The function traverse_for_phrases is invoked by a command in a `.i6t` template file.

§7. Just before noon.

```
void register_phrase_meanings(void) {
    advance_phrase_time_to(PRE_NOON_PHT);
    ph_To_register_all();
}
```

The function register_phrase_meanings is invoked by a command in a `.i6t` template file.

§8. **Early afternoon.** The three main routines here have to happen in sequence in order to work as intended; the PushDir warning is less crucial.

Note that the PHRCDs have to be parsed in source text appearance order (the order which `LOOP_OVER` works in) so that the back reference "doing it" (meaning, the most recently mentioned action) can work.

```
void parse_rule_parameters(void) {
    phrase *ph;
    advance_phrase_time_to(EARLY_AFTERNOON_PHT);
    LOOP_OVER(ph, phrase) {
        current_sentence = ph->declaration_node;
        phsf_select_stack_frame_of(ph);
        ph->runtime_context_data = phrcd_from_phud(&(ph->usage_data));
        phsf_remove_nonphrase_stack_frame();
        finish_this_session_of_parsing();
    }
}
void add_rules_to_rulebooks(void) {
    advance_phrase_time_to(EARLY_AFTERNOON_PHT);
    br_add_rules_to_rulebooks();
}
void parse_rule_placements(void) {
    parse_node *p;
```

```
    advance_phrase_time_to(EARLY_AFTERNOON_PHT);
    for (TREE_START(p); p; TREE_NEXT(p))
        if ((pn_get_node_type(p) == SENTENCE_NT) &&
            (p->down) &&
            (pn_get_node_type(p->down) == VERB_NT)) {
            prevailing_mood = pn_int_annotation(p->down, verbal_certainty_ANNOT);
            switch(pn_int_annotation(p->down, verb_id_ANNOT)) {
                case IN_RULEBOOK_VB:
                    place_in_rulebook(p->down->next, p->down->next->next, TRUE);
                    pn_annotate_int(p, sentence_unparsed_ANNOT, TRUE);
                    break;
                case NOT_IN_RULEBOOK_VB:
                    place_in_rulebook(p->down->next, p->down->next->next, FALSE);
                    pn_annotate_int(p, sentence_unparsed_ANNOT, TRUE);
                    break;
            }
            finish_this_session_of_parsing();
        }
}
```

The function parse_rule_parameters is invoked by a command in a `.i6t` template file.
The function add_rules_to_rulebooks is invoked by a command in a `.i6t` template file.
The function parse_rule_placements is invoked by a command in a `.i6t` template file.

§9. Mid-afternoon.

```
void compile_phrases(OUTPUT_STREAM) {
    int i = 0, max_i = 0;
    phrase *ph;
    rulebook *rb;
    advance_phrase_time_to(MID_AFTERNOON_PHT);
    LOOP_OVER(ph, phrase)
        if (ph->compilation_needed)
            max_i++;
    ph_To_compile_all(OUT, &i, max_i);
    WRITE("! Definitions of rule phrases\n\n");
    LOOP_OVER(rb, rulebook)
        rb_compile_rule_phrases(rb, OUT, &i, max_i);
    if (i < max_i) {
        booked_rule *br;
        WRITE("! Definitions of displaced and unbooked rules\n\n");
        LOOP_OVER(br, booked_rule) {
            ph = br_get_rule(br);
            if (ph)
                ph_compile(ph, OUT, &i, max_i, br_stvol_accessible_here(br));
        }
    }
    if (i < max_i) {
        WRITE("! Definitions of miscellaneous remaining rules\n\n");
        LOOP_OVER(ph, phrase)
            ph_compile(ph, OUT, &i, max_i, NULL);
    }
}
```

The function compile_phrases is invoked by a command in a .i6t template file.

§**10. Evening.** These miscellaneous compilations can happen in any order, as suits the needs of the Main.i6t script.

```
void resolve_predeclared_booked_rules(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    br_resolve_predeclared_booked_rules(OUT);
}
void compile_adjectival_phrases(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    aph_compile_support_code(OUT);
}
void compile_TimedEventsTable_array(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    tiph_compile_TimedEventsTable_array(OUT);
}
void compile_TimedEventTimesTable_array(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    tiph_compile_TimedEventTimesTable_array(OUT);
}
void compile_rulebooks_array_array(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    rb_compile_rulebooks_array_array(OUT);
}
void compile_rulebooks(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    rb_compile_rulebooks(OUT);
}
void compile_RulebookNames_array(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    rb_compile_RulebookNames_array(OUT);
}
void compile_rule_printing_switch(OUTPUT_STREAM) {
    advance_phrase_time_to(EVENING_PHT);
    br_compile_rule_printing_switch(OUT);
}
```

The function resolve_predeclared_booked_rules is invoked by a command in a .i6t template file.
The function compile_adjectival_phrases is invoked by a command in a .i6t template file.
The function compile_TimedEventsTable_array is invoked by a command in a .i6t template file.
The function compile_TimedEventTimesTable_array is invoked by a command in a .i6t template file.
The function compile_rulebooks_array_array is invoked by a command in a .i6t template file.
The function compile_rulebooks is invoked by a command in a .i6t template file.
The function compile_RulebookNames_array is invoked by a command in a .i6t template file.
The function compile_rule_printing_switch is invoked by a command in a .i6t template file.

Phrases 12/ph

Purpose

To create one `phrase` object for each phrase declaration in the source text.

12/ph.§1-2 Problem messages for complex say constructions

Definitions

¶1. This is the largest structure, in terms of number of fields, found anywhere in NI. To keep some kind of control over this complexity, it is divided into sub-structures handling different purposes, and which are available at different times. Of particular note is the stack frame: for a phrase, this is a function of the type data, but it is also possible to generate a stack frame in a free-standing way in order to compile code which does not derive from a phrase declaration (for instance, to compile a routine to print a piece of text which contains substitutions).

These structures are, as far as possible, private to their own sections. Within this chapter, all sections have access to the substructure elements of `phrase`. Outside this chapter, only the PHTD substructure is directly visible, and then only to Chapter 7 (on type-checking). The other elements of `phrase` are private.

The substructures themselves are private to their sections except that `type_data` is shared with two sections from Chapter 7, and that `ph_runtime_context_data` is shared between two sections of Chapter 12 (since a PHRCD is essentially generated from a PHUD, there is no sensible way to separate code which performs this generation into a PHRCD-owned part and a PHUD-owned part).

```
typedef struct phrase {
    struct parse_node *declaration_node;                    ROUTINE_NT node where declared
    int inline_wn;                                  word number of inline I6 definition, or -1 if not inline
    struct ph_type_data type_data;
    struct ph_usage_data usage_data;
    struct ph_runtime_context_data runtime_context_data;
    struct ph_stack_frame stack_frame;
    struct ph_options_data options_data;
    int compilation_needed;                          do we still need to compile an I6 routine for this?
    char ph_I6_identifier[32];                     name of I6 routine, or empty string for inline phrases
    struct phrase *next_in_logical_order;                                  for "to..." phrases only
    int sequence_count;                                          within the logical order list, from 0
    int ph_documentation_symbol_wn;                              cross-reference with documentation
    MEMORY_MANAGEMENT
} phrase;
```

The structure phrase is shared with 7/vasp, 7/tc, 7/inv, 11/av, 12/cs, 12/phrcd, 12/phtd, 12/phsf, 12/cinv, 12/ambig, 12/cph, 12/toph, 12/phin, 12/tiph and 12/br.

```
phrase *ph_new(ph_usage_data *phud, ph_type_data *phtd, ph_options_data *phod,
    int d, int inline_wn) {
    phrase *ph = CREATE(phrase);
    LOGIF(PHRASE_CREATIONS, "Creating phrase: <$W>\n$U",
        phud_get_preamble_w1(phud), phud_get_preamble_w2(phud), phud);
    if ((current_sentence == NULL) ||
        (pn_get_node_type(current_sentence) != ROUTINE_NT))
        internal_error("Phrase creation other than at a ROUTINE_NT node");
```

```
    ph->declaration_node = current_sentence;
    ph->usage_data = *phud;
    ph->type_data = *phtd;
    ph->stack_frame = phtd_to_stack_frame(phtd);
    if (phod_allows_options(phod))
        phsf_options_parameter_is_needed(&(ph->stack_frame));
    ph->runtime_context_data = phrcd_new();
    ph->options_data = *phod;
    ph->next_in_logical_order = NULL;
    ph->sequence_count = -1;
    ph->inline_wn = inline_wn;
    if (inline_wn >= 0) {
        char *inline_defn = lw_array[inline_wn].lw_text;
        if (strlen(inline_defn) >= MAX_INLINE_DEFN_LENGTH) {
            LOG("Inline definition: <$W>\n", inline_wn, inline_wn);
            sentence_problem(_P_(C12InlineTooLong),
                "the inline definition of this 'to...' phrase is too long",
                "using a quantity of Inform 6 code which exceeds the fairly "
                "small limit allowed. You will need either to write the "
                "phrase definition in Inform 7, or to call an I6 routine "
                "which you define elsewhere with an 'Include ...'.");
            inline_defn[MAX_INLINE_DEFN_LENGTH-1] = 0;
        }
        if (phud_get_RAM(phud) != PHRASE_DECLARATION_RAM) {
            sentence_problem(_P_(C12InlineRule),
                "only 'to...' phrases can be given inline Inform 6 definitions",
                "and in particular rules and adjective definitions can't.");
        }
        ph->compilation_needed = FALSE;
        ph->ph_I6_identifier[0] = 0;
    } else {
        ph->compilation_needed = TRUE;
        sprintf(ph->ph_I6_identifier, "R_%d", ph->allocation_id);
    }
    ph->ph_documentation_symbol_wn = d;
    return ph;
}
void log_phrase(phrase *ph) {
    if (ph == NULL) { LOG("RULE:NULL"); return; }
    LOG("%s", ph->ph_I6_identifier);
    phud_log_rule_name(&(ph->usage_data));
}
char *ph_get_I6_representation(phrase *ph) {
    return ph->ph_I6_identifier;
}
void ph_write_HTML_representation(phrase *ph, char *to) {
    phtd_write_HTML_representation(&(ph->type_data), to);
}
void log_phrase_briefly(phrase *ph) {
    log_ph_type_data_briefly(&(ph->type_data));
}
```

```
void ph_compile(phrase *ph, OUTPUT_STREAM, int *i, int max_i,
    stacked_variable_owner_list *legible) {
    if (ph->compilation_needed) {
        compile_phrase(OUT, ph, legible);
        ph->compilation_needed = FALSE;
        (*i)++;
        progress_bar(4, ((float) (*i))/((float) max_i));
    }
}
```

The function log_phrase is called from 2/dl and 12/toph.

The function ph_get_I6_representation is called from 12/cinv, 12/cph, 12/toph, 12/def, 12/tiph and 12/br.

The function ph_write_HTML_representation is called from 2/prob2, 12/phtd and 12/toph.

The function log_phrase_briefly is called from 7/inv.

The function ph_compile is called from 12/cs, 12/toph and 12/br.

§1. Problem messages for complex say constructions.

```
void add_say_construction_to_error(int ssp_tok) {
    issue_problem_segment(" %P(The construction I'm thinking of is '");
    add_scte_list(ssp_tok, SSP_START);
    issue_problem_segment(" ... ");
    add_scte_list(ssp_tok, SSP_MIDDLE);
    issue_problem_segment(" ... ");
    add_scte_list(ssp_tok, SSP_END);
    issue_problem_segment("'.)");
}
void add_scte_list(int ssp_tok, int list_pos) {
    phrase *ph; int ct = 0, w1, w2;
    LOOP_OVER(ph, phrase)
        if (phtd_ssp_matches(&(ph->type_data), ssp_tok, list_pos, &w1, &w2)) {
            quote_words(3, w1, w2);
            if (ct++ == 0) issue_problem_segment("[%3]"); else issue_problem_segment("/[%3]");
        }
}
```

The function add_say_construction_to_error is called from 12/cinv.

§2. The following routine is the one which constructs a phrase object from the parse-tree representation of a declaration in the source text. This is the only routine in NI which contains the definition of what an inline declaration looks like:

A phrase is inline if and only if its definition consists of a single invocation which is given as verbatim I6.

```
void ph_create_from_preamble(parse_node *p) {
    phrase *current_phrase;
    ph_usage_data phud;
    ph_type_data phtd;
    ph_options_data phod;
    int x1, x2, ow1 = -1, ow2 = -1, inline_flag = FALSE, inline_wn = -1, ds = -1;
    if ((p == NULL) || (pn_get_node_type(p) != ROUTINE_NT))
        internal_error("ph_create_from_preamble other than at a ROUTINE_NT node");
    if ((p->down) && (p->down->next == NULL) && [[p->down == OPENI6 ...]]) {
        inline_flag = TRUE;
        inline_wn = p->down->word_ref1 + 1;
```

```
    }
    phud = phud_new(p->word_ref1, p->word_ref2, FALSE);
    x1 = phud_get_preamble_w1(&phud); x2 = phud_get_preamble_w2(&phud);
    switch (phud_get_RAM(&phud)) {
        case PHRASE_DECLARATION_RAM:
            ds = dref_position_of_symbol(&x1, &x2, FALSE);
            phtd = phtd_parse(x1, x2, &ow1, &ow2, inline_flag);
            break;
        case DEFINING_AN_ADJECTIVE_RAM:
            phtd = phtd_new(DECIDES_CONDITION_MOR);
            break;
        default:
            phtd = phtd_new(DECIDES_NOTHING_AND_RETURNS_MOR);
            break;
    }
    if (ow1 >= 0) phod = phod_parse_declaration(ow1, ow2);
    else phod = phod_new();
    current_phrase = ph_new(&phud, &phtd, &phod, ds, inline_wn);
    switch (phud_get_RAM(&(current_phrase->usage_data))) {
        case PHRASE_DECLARATION_RAM:
            ph_To_make(current_phrase);
            break;
        case DEFINING_AN_ADJECTIVE_RAM: {
            int cw1, cw2;
            join_phrase_to_adjective(p, current_phrase, &cw1, &cw2);
            phsf_add_it_variable(&(current_phrase->stack_frame), cw1, cw2, kova(OBJECT_TY));
            break;
        }
        case RULE_IN_RULEBOOK_RAM:
        case RULE_NOT_IN_RULEBOOK_RAM:
            phud_create_primary_booking(&(current_phrase->usage_data),
                current_phrase);
            break;
    }
}
```

The function ph_create_from_preamble is called from 12/cs.

Phrase Usage 12/phud

Purpose

To parse the preamble of a phrase declaration to a `ph_usage_data` (PHUD) structure containing a still mostly textual representation of the conditions for its usage; to issue problem messages diagnosing bad syntax in these preambles; later, to parse further in order to convert the PHUD to a no longer textual PHRCD structure; finally, to use a PHUD to create a suitable primary booked rule (BR) for any phrase destined to be a rule, employing any predeclared BR for the phrase which may exist.

12/phud.§1 Construction; §2 How the PHUD translates into a PHRCD; §3 Problem messages for misphrased rule preambles; §4-5 Activation of rules

---

Definitions

¶1. "Attachment" is the process by which a phrase is placed into the data structures of the I6 program being compiled by NI. There are four ways this can be done:

```
define AS_YET_UNKNOWN_RAM 0                          used only temporarily during header parsing
define PHRASE_DECLARATION_RAM 1                      "To award (some - number) points: ..."
define RULE_IN_RULEBOOK_RAM 2                        "Before taking a container, ..."
define RULE_NOT_IN_RULEBOOK_RAM 3                    "At 9 PM: ...", "This is the zap rule: ..."
define DEFINING_AN_ADJECTIVE_RAM 4                   "Definition: a container is roomy if..."

typedef struct ph_usage_data {
    int full_preamble_w1, full_preamble_w2;          e.g. to identify nameless rules in the log
    int rule_attachment_mode;                        see below: basically, how the phrase is invoked
    int timing_of_event;                             one of two values defined below; or a specific time
    int explicit_name_w1, explicit_name_w2;          if a named rule, this is its name
    int whenwhile_w1, whenwhile_w2;                  when/while for action/activity rulebooks
    int rule_preamble_w1, rule_preamble_w2;
    int rule_parameter_w1, rule_parameter_w2;        text of object or action parameter
    struct specification *during_scene_spec;         what scene is currently under way
    int event_name_w1, event_name_w2;
    struct rulebook *owning_rulebook;                the primary booking for the phrase will be here
    int owning_rulebook_placement;                   ...and with this placement value: see Rulebooks
    int index_with_data_type;                        UNKNOWN, or the data type which created this
} ph_usage_data;
```

The structure ph_usage_data is private to this section.

¶2. When the following flag is set, we are parsing the header of a phrase to see if it might be a rule being attached to a rulebook, such as "Before taking a fish, ...". The flag is used to tell the parser that "in..." and "when..." have special meanings to do with providing circumstances for the rule to apply – this considerably cuts down on awkward ambiguities.

```
int rule_circumstances_mode = FALSE;
```

```
void log_ph_usage_data(ph_usage_data *phud) {

The function phud_print_preamble_to is called from 12/tiph.

§1. **Construction.** The following construction function produces a phud given the text of a phrase's preamble. It is designed so that it can be used as often as necessary in "coarse mode", but should be run once and once only on any given phrase when in "fine mode".

In its coarse mode, it uses only lexical data, and thus can work very early in NI's run – before it is known what the rulebooks, scenes and so forth will be called, for instance. Coarse mode does not provide detailed usage information for `RULE_IN_RULEBOOK_RAM` rules, but it does get everything else right. (This is only possible because an ambiguity was removed in December 2006, removing the possibility of "when" introducing rules of two different RAMs – see below.)

```
int no_now_phrases = 0;

ph_usage_data phud_new(int w1, int w2, int coarse_mode) {
    ph_usage_data phud;
    rulebook_match rm;
    int i, rw1, rw2, without_when_w1 = -1, without_when_w2 = -1;
    phud.full_preamble_w1 = w1; phud.full_preamble_w2 = w2;
    phud.rule_attachment_mode = AS_YET_UNKNOWN_RAM;
    phud.explicit_name_w1 = -1; phud.explicit_name_w2 = -1;
    phud.rule_preamble_w1 = -1; phud.rule_preamble_w2 = -1;
    phud.rule_parameter_w1 = -1; phud.rule_parameter_w2 = -1;
    phud.whenwhile_w1 = -1; phud.whenwhile_w2 = -1;

Phrase Runtime Context Data 12/phrcd

Purpose

To create, logically compare the specificity of, and compile I6 tests which check the current validity of, the circumstances in which a rule phrase should be used. All interesting PHRCD structures are manufactured from PHUDs, however, and the code for that is found in the Phrase Usage section.

12/phrcd.§1 Specificity of phrase runtime contexts

Definitions

¶1. Runtime context data is the context in which a phrase is allowed to run. It is deduced from the PHUD (and the code is inherited from 12/phud); it is tested at runtime in the phrase's defining routine.

```
typedef struct ph_runtime_context_data {
    int activity_context_w1, activity_context_w2;          happens only while any activities go on?
    struct specification *during_scene;                    ...happens only during any particular scene?
    struct action_pattern ap;                              happens only if the action matches this pattern?
    int always_test_actor;                                 ...even if no AP was given, test that actor is player?
    int never_test_actor;                                  ...for instance, for a parametrised rather than action rulebook
    struct rulebook *compile_for_rulebook;                 ...used for the default outcome
    int permit_all_outcomes;                               waive the usual restrictions on rule outcomes
} ph_runtime_context_data;
```

The structure ph_runtime_context_data is shared with 12/phud.

```
ph_runtime_context_data phrcd_new(void) {
    ph_runtime_context_data phrcd;
    phrcd.activity_context_w1 = -1;
    phrcd.activity_context_w2 = -1;
    phrcd.during_scene = NULL;
    phrcd.ap = new_action_pattern();
    phrcd.always_test_actor = FALSE;
    phrcd.never_test_actor = FALSE;
    phrcd.permit_all_outcomes = FALSE;
    phrcd.compile_for_rulebook = NULL;
    return phrcd;
}
scene *phrcd_get_scene(ph_runtime_context_data *phrcd) {
    if (phrcd == NULL) return NULL;
    if (family_is(phrcd->during_scene, VALUE_FMY)) {
        quantity *q = spec_get_constant_quantity_if_any(phrcd->during_scene);
        if ((q) && (qty_is_a_scene_name(q))) return read_scene_from_quantity(q);
    }
    return NULL;
}
int phrcd_within_action_context(ph_runtime_context_data *phrcd,
    action_name *an) {
    if (phrcd == NULL) return FALSE;
    return ap_within_action_context(&(phrcd->ap), an);
}
```

```
action_name *phrcd_required_action(ph_runtime_context_data *phrcd) {
    if (ap_is_valid(&(phrcd->ap)))
        return ap_required_action(&(phrcd->ap));
    return NULL;
}

The function outcome_restrictions_waived is called from 12/rb.

§1. **Specificity of phrase runtime contexts.** The following is one of NI's standardised comparison routines, which takes a pair of objects A, B and returns 1 if A makes a more specific description than B, 0 if they seem equally specific, or −1 if B makes a more specific description than A. This is transitive, and intended to be used in sorting algorithms.

```
int compare_specificity_of_phrcd(ph_runtime_context_data *rcd1,
    ph_runtime_context_data *rcd2) {
    specification *sc1 = NULL, *sc2 = NULL;
    int al1 = -1, al2 = -1;

Phrase Type Data 12/phtd

Purpose

To create, manage, compare the logical specificity of, and assist excerpt parsing concerning, the type of a To phrase. This involves whether it is void, determines a condition or returns a value (and if so, what kind of value); and also what parameters it takes (possibly values, possible other types used by inline definitions) and their types in turn.

12/phtd.§8 Comparison of PHTDs; §9 Parsing of phrases; §10 Adding invocations to phrase SPs

---

Definitions

¶1. Phrases declared with the words "To say..." define new text substitution. The first to be defined is special: it will be "to say [value]". Others which implement control structures also need special treatment.

```
define NOT_A_SAY_PHRASE 0                    needs to be 0 so that say_phrase can be a C condition
define A_MISCELLANEOUS_SAY_PHRASE 1
define THE_PRIMORDIAL_SAY_PHRASE 2

define NO_SAY_CS 0
define IF_SAY_CS 1
define OTHERWISE_SAY_CS 2
define END_IF_SAY_CS 3
```

¶2. The `manner_of_return` field for a phrase's type shows what it does. The exceptional case is the last, `DECIDES_NOTHING_AND_RETURNS_MOR`, which marks out a phrase which exits the phrase it is part of the definition of – like the keyword `return` in a C function.

We enumerate from 2 here so that `UNKNOWN` can be used as a "don't know what the manner is" value.

```
define DECIDES_NOTHING_MOR 2                                   e.g., "award 4 points"
define DECIDES_VALUE_MOR 3                                     e.g., "square root of 16"
define DECIDES_CONDITION_MOR 4                                 e.g., "a random chance of 1 in 3 succeeds"
define DECIDES_NOTHING_AND_RETURNS_MOR 5                       e.g., "continue the action"
```

¶3. Only in the case of DECIDES_VALUE_MOR does the phrase produce data which can be used as a value, and in this event the type-checking code needs to know what the data type of the value is. Arithmetic phrases are polymorphic in this respect: that is, the type of the result of "X plus Y" depends on the types of X and Y. Other phrases always have definite data types, though, and these are recorded in the `return_type` field.

```
define MAX_TOKENS_PER_PHRASE 10
define MAX_WORDS_PER_PHRASE 32                                  the most the excerpt parser can hold anyway

typedef struct ph_type_data {
    int register_w1, register_w2;                               words used to register the excerpt meaning
    int manner_of_return;                                       one of the *_MOR values – see above
    struct specification *return_type;                          well, if not arithmetical
    int words[MAX_WORDS_PER_PHRASE];                            the "word sequence": see above
    int no_words;                                               length of the word sequence
    int tokens_w1[MAX_TOKENS_PER_PHRASE], tokens_w2[MAX_TOKENS_PER_PHRASE];   names
    struct specification *tokens_spec[MAX_TOKENS_PER_PHRASE];   type expected
    struct kind_of_value *tokens_template[MAX_TOKENS_PER_PHRASE];   for variable types
    int no_tokens;
    int say_phrase;                                             one of the three values above
    int say_phrase_running_on;                                  ignore implied newlines in previous invocation
    int say_phrase_stream_position;                             special position in say stream, if any
    int say_phrase_stream_token_at;                             word number of say stream token name
    int say_phrase_stream_closing_token_at;                     ditto for choice of ending
    int say_control_structure;                                  one of the four values above
    int let_phrase;                                             is this "let A be B", where A is as yet unknown?
    int includes_a_QUOT_token;                                  is one of the token types VALUE/QUOT?
    int block_follows;                                          for inline phrases only: followed by a begin... end block?
    int only_in_block_wn;                                       -1, or the name of the block this must occur inside
    int only_in_loop;                                           if TRUE, then the phrase can only be used in a loop body
    int arithmetical_operation;                                 -1, or one of the five operators – see Types
    int polymorphism_exception;                                 -1, or an exception to the type returned rules
    int assignment_exception;                                   TRUE if this has to be typechecked as an assignment
    int invoked_inline_not_as_call;                             TRUE, FALSE or NOT APPLICABLE for non-phrases
} ph_type_data;
```

The structure ph_type_data is shared with 7/tc, 7/inv, 12/phsf and 12/cinv.

¶4. A phrase whose invocations are compiled inline, like "award (some - a number) points", does have token names with scope local to its own schematic definition – short-lived as that is. It also has phrase options; but it has no local variables of its own, as such, since it has to live inside another routine. Instead, it has the right to claim new locals as needed: for instance, a phrase for a loop will need to claim at least one local as a loop counter, and indeed some loops claim two. The following variable holds the local variable number of whatever was most recently created.

```
int phrase_made_local = -1;
```

¶5. The say stream is the sequence of successive invocations in a single say, or in a piece of text with substitutions. Some say phrases are compound in that they must occur in a given sequence (for instance, say end if makes sense only if it follows a matching say if earlier in the stream, though for various reasons this isn't actually how that is implemented).

The following markers are used to identify such say phrases:

```
define SSP_NONE 0
define SSP_START 1
define SSP_MIDDLE 2
define SSP_END 3
```

¶6. The following codes describe the possible ways routines can return values: not at all, the standard way, or polymorphically – which is used for arithmetic operations, whose KOV is determined by the KOVs of the operands. These are not type IDs and cannot be used as such.

```
define NO_RETURN_RTY   1
define POLYMORPHIC_RTY 2
define STANDARD_RTY 3
```

Phrase Options 12/phod

Purpose

To create and subsequently parse against the list of phrase options with which the user can choose to invoke a To phrase.

Definitions

¶1. A "phrase option" is a sort of modifier tacked on to the instruction to do something, changing how it works but not enough to merit an entirely new phrase. It's like an argument passed to a routine which specifies optional behaviour, and indeed that will be how it is compiled. Individual phrase options are stored in a very rudimentary structure at present, but we take the trouble to hold them in a structure because we may one day wish to use them in diagnosing errors.

The end of the header (the chin? the neck?) is an optional comma and then a list of phrase options. Like the token names, phrase option names have local scope (which is why they are here and not in the excerpts database). Unlike them, they are not valid as values, which is where parsing time is eaten up: only as conditions, which are parsed much less often (since a condition is not also a value in Inform 7). That means we need not go to the trouble of hashing the names, saving nuisance.

```
typedef struct phrase_option {
    int word_ref1, word_ref2;                                   text of name
} phrase_option;
```

The structure phrase_option is private to this section.

¶2. The packet of these associated with a phrase is stored in the PHOD structure.

```
define MAX_OPTIONS_PER_PHRASE 16                    because held in a 16-bit Z-machine bitmap

typedef struct ph_options_data {
    struct phrase_option *options_permitted[MAX_OPTIONS_PER_PHRASE];    see below
    int no_options_permitted;
    int options_w1, options_w2;                     the text declaring the whole set of options
    int multiple_options_permitted;                 can be combined, or mutually exclusive?
} ph_options_data;

Stack Frames 12/phsf

Purpose

To create, and parse local value names within the context of, stack frames. A stack frame is a context in which sequences of void-phrase expression evaluations can be performed, that is, in which procedural code can be compiled. Each phrase compiled to an I6 routine needs such a context, but a stack frame can also arise when other routines not derived from phrases are being compiled. In this section we also manage the beginning and ending of code blocks (as in "If ... begin; ...; end if").

12/phsf.§1 Parsing; §2 The current stack frame; §3-5 The current block stack

---

Definitions

¶1. There are three sets of names with scope local to the definition of a given phrase: the names of its tokens, of its phrase options, and of its loop variables and "let" values. The header for a phrase declaration will be something like

To award (some - number) points: ...

and the *words sequence* of this phrase is "to", "award", token 0, "points": a sequence of length 4. If the above text occurred at words 561 to 569, the words sequence would be 561, 562, 0, 568. In the words sequence, numbers above 10 are taken as word numbers in the source; numbers from 0 to 9 indicate the presence of a *token*, where some textual content is substituted. For each token, we record its name ("some"), a hash code for its name – since names like this one will need to parsed against frequently when compiling the phrase's definition routine – and a specification which indicates the type of expression we expect to be find in this position.

Note that this is a full SP, not a mere data type. If the phrase is to compile to an I6 routine, then this will indeed be `VALUE/D` for some data type `D`. But if it is to compile inline, then a much wider range of possibilities presents itself: a condition, or a sentence capable of being asserted with "now", a phrase, etc.

¶2. Supposing that the phrase compiles to a routine, it will use local I6 variables to store the token values and a bitmap of the phrase option settings; and also for any local variables needed in the routine for loop variables, "let" values, etc. In effect, NI is in the same position as a traditional compiler which must allocate its values – of which there might be any number – to registers in a CPU, of which there are only a finite number. Here, our registers are the 15 local variables allowed in any single Z-machine routine: I6's restriction of only 15 locals for any single function is because it performs no "register allocation" and maps its local variables directly onto Z-machine locals.

NI, on the other hand, has a less literal mapping. These variables are allocated and deallocated as needed in the course of compiling the routine: for instance, a loop variable is allocated at the start of a loop and deallocated at the end. It then vanishes as an I7 name, but the I6 local variable holding it may be re-used to hold another I7 value further down the same routine.

The most complicated form such an I6 function can take resembles the following example:

```
[ R_314 t_0 t_1 phrase_options t_2 t_3 t_4 ct_0 ct_1;
```

where there are two tokens passed to the routine (`t_0` and `t_1`), and there are phrase options (whose bitmap is in `phrase_options`), and at the busiest point in the routine three temporary values are needed at once (`t_2`, `t_3`, `t_4`), and finally table-row selection will be going on, so that we need to record a choice of table (`ct_0`) and row number within that table (`ct_1`). A typical invocation of this example phrase would compile to I6 like so:

```
R_314(20, O31_black_marble_slab, 16);
```

It is perhaps worth stopping to ask ourselves why it is helpful for values to be in local variables. Unlike traditional register allocation, this is not done for any speed gain – in the Z-machine, there is no particular

advantage to a local vs a global variable. The actual reason is to place a value in the stack frame for the current routine. For instance, each phrase must have its own "currently selected table row": it would not do for one phrase which uses another one to find that the table row had been deselected as a side-effect. So `ct_0` and `ct_1` have to be locals, not globals. In a few cases, we can get something into the stack frame without having to use up a precious local: we do this trick to hold the current state of conditional text printing brought about by "say if" text substitutions, where the value in question is a global variable which is pushed onto the Z-machine stack, then overwritten, used for a whole, and then restored to its original value by pulling from the stack. But this trick is only possible if we are absolutely sure that we will be in a position to pull the value from the stack when we are done: and with `ct_0` and `ct_1`, we have no such certainty.

```
typedef struct local_variable {
    int allocated;                                  currently in use at this point in the routine
    int varname_w1, varname_w2;                     name of local variable

¶3. One further name is sometimes local to a phrase: or rather, not so much the name as its possessive form. This is "its", "his", "her" or "their", and in some definitions this can stand for "the thing to which the definition applies". The following variable holds `-1` if this is disallowed, or else the local variable number referred to by these pronouns if it is allowed.

```
int enable_its = -1;
```

```

§**1. Parsing.** Locally defined values are parsed by hand, not via the dictionaries, because they come and go on the breeze: although our symbols table is well-adapted to many things, it is not a true hash, and there is a real reward for not allowing it to grow unnecessarily. So we do not want to register the locals as meanings. We do use the excerpt hashing to make the parse reasonably quick, though: and there are only ever at most 15 cases to check.

```
int phsf_parse_name(ph_stack_frame *phsf, int w1, int w2) {
    int i, h;

§**2. The current stack frame.** At any given time, a single stack frame is valid for local variable names and phrase option names used as conditions. This might be the stack frame of the current "To..." phrase being defined, or it might be a free-standing stack frame which is "nonphrasal", meaning, not a `.stack_frame` element of any phrase structure. Stack frames change during compilation and are liable to be destroyed when compilation is complete, so pointers to them must not be stored for later use.

```
int nonphrasal_stack_frame_is_current = FALSE;
ph_stack_frame nonphrasal_stack_frame;

ph_stack_frame *current_stack_frame(void) {

§**3. The current block stack.** During code compilation, we must keep track of statement blocks: those defined by begin... end keywords. We need these partly to ensure that the control flow is correct, partly to deallocate local variables when they are no longer needed (for instance, a repeat variable does not exist outside its loop).

In principle, this information belongs to the current stack frame, since it's within the context of a stack frame that code is compiled. But it would be wasteful to store arrays for statement blocks inside every stack frame structure, because in practice we only compile within one stack frame at a time, and we finish each before beginning the next. So we store the block stack in the only instance of a private structure.

```
define MAX_BLOCK_NESTING 20

§5. An example: how we compile a routine to test a single condition.

```
void compile_condition_routine(OUTPUT_STREAM, char *rname,
    int w1, int w2, bp_term_details par1, bp_term_details par2) {
    specification *spec;
    ph_stack_frame *phsf;

    phsf = phsf_create_nonphrase_stack_frame();
    OUT = begin_compiling_phrase(OUT);
    begin_code_blocks();

    bptd_add_as_call_parameter(OUT, phsf, par1);
    bptd_add_as_call_parameter(OUT, phsf, par2);

    enable_its = 0;
    spec = parse_expression(w1, w2, CONDITION_EXPCON);
    if (validate_when(spec) == FALSE) {
        LOG("Error at: $S", &spec);
        sentence_problem(_P_(C12BadRelationCondition),
            "the condition defining this relation makes no sense to me",
            "although the definition was properly formed - it is only "
            "the part after 'when' which I can't follow.");
    } else {
```

```
        INDENT;
        WRITE("return "); spec_compile(OUT, spec); WRITE(";\n");
        OUTDENT; WRITE("];\n");
    }
    OUT = write_routine_header();
    WRITE("[ %s ", rname);
    copy_compiled_phrase();
    end_code_blocks();
    phsf_remove_nonphrase_stack_frame();
}
```

The function compile_condition_routine is called from 5/rel.

Stacked Variables 12/stv

Purpose

To permit quantities to belong to rulebooks, and to have limited name-scope.

Definitions

```

Compile Invocations 12/cinv

Purpose

Here we generate Inform 6 code to execute the phrase(s) called for by an invocation list.

Template interpreter commands

```
2   {-callv:compile_list_together_routines}
21  {-callv:compile_resolver_routines}
```

Definitions

¶1. The arguments packet. Just a data structure used in assembling phrases for compilation. Unlike most NI structures, these do not hang around in memory for any length of time, and are not worth further comment.

```
typedef struct args_packet {
    int args_count;                                  number of arguments to phrase
    struct specification *args[32];                  what they are
    struct kind_of_value *pointer_kov[32];           what pointer kinds of value, if they are
} args_packet;
```

The structure args_packet is private to this section.

¶2. List together routines. Another uninteresting data structure. One of these is created for each distinct routine needed as a value of the I6 property `list_together` at run-time.

```
typedef struct list_together_routine {
    int articles_bit;                                if false, add NOARTICLE_BIT to the I6 listing style
    MEMORY_MANAGEMENT
} list_together_routine;
```

The structure list_together_routine is private to this section.

¶3.

define `MAX_INLINE_DEFN_LENGTH 1024`

---

§**1. Compilation of invocations.** Recall that a phrase SP contains a list of invocations, batched into groups. Each group contains a range of possible things to do, to be distinguished by run-time type checking: only one will ever happen. (So for unambiguous code, a group consists of a single invocation.) In this section we take such a SP and compile the I6 code which carries it out. There are three levels: bottom level, a single invocation; middle level, a group of invocations; and top level, the entire list.

In fact, before we can get to the actual compilation, we need to supply some support infrastructure for the extraneous material which can also sometimes be compiled in the course of an invocation.

§**2. List together routines.** These are minimal data structures. Each time we request an LTR we get a fresh numerical ID `N`, and the I6 source code then contains a routine with name `LTR_N`. The source for this routine is always one of only two possibilities, so it looks rather odd to keep generating fresh copies. We do this so that the routine addresses can be used as distinct values of the `list_together` property at run-time, because the I6 library uses distinctness of this property value to determine whether things are or are not listed together.

```
int new_list_together(int include_articles) {
    list_together_routine *ltr = CREATE(list_together_routine);
    ltr->articles_bit = include_articles;
    return ltr->allocation_id;
}
void compile_list_together_routines(OUTPUT_STREAM) {
    list_together_routine *ltr;
    LOOP_OVER(ltr, list_together_routine) {
        WRITE("[ LTR_%d;\n", ltr->allocation_id); INDENT;
        WRITE("if (inventory_stage == 1) {\n"); INDENT;
        if (ltr->articles_bit)
            WRITE("c_style = c_style | (ENGLISH_BIT);\n");
        else
            WRITE("c_style = c_style | (ENGLISH_BIT + NOARTICLE_BIT);\n");
        WRITE("c_style = c_style &~ (NEWLINE_BIT + INDENT_BIT);\n");
        OUTDENT; WRITE("}\n");
        WRITE("rfalse;\n");
        OUTDENT; WRITE("];\n");
    }
}
```

The function compile_list_together_routines is invoked by a command in a `.i6t` template file.

§**3. Function calls for phrases.** When an invocation of a phrase is compiled, it either becomes a function call to a function like `R_102`, or else it is compiled using an "inline definition" into other I6 statements. The following routine compiles the `R_102(...)` function call needed for non-inline-definitions, then. But it is also used for calls like `Resolver_3(...)` used to perform run-time type checking; and for that, we need to know where the phrase came from in the source text, so that an informative run-time problem message can be produced if that type-checking should fail.

```
void compile_function_call(OUTPUT_STREAM, source_location *where_from,
    args_packet *argsp, int resolver, char *identifier, int phrase_options,
    kind_of_value *block_type_returned, kind_of_value *block_resolved,
    int within_resolver) {
    int k, ar = 0;
    BEGIN_COMPILATION_MODE;
    COMPILATION_MODE_ENTER(DEREFERENCE_POINTERS_CMODE);
    WRITE("(%s(", identifier);
    if (block_type_returned) {
        if (ar++ > 0) WRITE(",");
        if (within_resolver) WRITE("rvblock");
        else {
            pointer_allocation *pall =
                phsf_add_allocation(block_type_returned, NULL);
            WRITE("%s", pall_get_local_reference(pall));
        }
```

```
    }
    for (k=0; k<argsp->args_count; k++) {
        int promote = FALSE, cmode = 0;
        if (ar++ > 0) WRITE(",");
        if ((TEST_COMPILATION_MODE(INSIDE_RESOLVER_CMODE) == FALSE) &&
            (argsp->pointer_kov[k] != NULL) &&
            (kov_compare(argsp->pointer_kov[k],
                spec_evaluates_to(argsp->args[k])) == FALSE))
            promote = TRUE;
        if (promote) {
            pointer_allocation *pall = phsf_add_allocation(argsp->pointer_kov[k], NULL);
            WRITE("BlkValueCast(%s, %d, %d, ",
                pall_get_local_reference(pall),
                kov_I6_ID(argsp->pointer_kov[k]),
                kov_I6_ID(spec_evaluates_to(argsp->args[k])));
            cmode = PERMIT_LOCALS_IN_TEXT_CMODE;
        }
        BEGIN_COMPILATION_MODE;
        COMPILATION_MODE_ENTER(cmode);
        spec_compile(OUT, argsp->args[k]);
        if (promote) WRITE(")");
        END_COMPILATION_MODE;
    }
    if (phrase_options != -1) {
        if (ar++ > 0) WRITE(",");
        WRITE("%d", phrase_options);
    }
    if (resolver) {
        if (ar++ > 0) WRITE(",");
        if (block_resolved) {
            pointer_allocation *pall = phsf_add_allocation(block_resolved, NULL);
            WRITE("%s", pall_get_local_reference(pall));
            if (ar++ > 0) WRITE(", ");
        }
        WRITE("\"source\", %d", where_from->line_number);
    }
    WRITE("))");
    END_COMPILATION_MODE;
}
```

§4. **Compiling single invocations.** Strictly speaking, the following routine does not quite compile the contents of an invocation: this is because it ignores the values of the tokens as parsed, and draws the necessary arguments from a "packet" passed alongside the invocation. Now in fact this packet will in almost all cases be the same as the set of values of tokens as parsed, but not when we are in a type-resolution routine; so it seems wisest to abstract the arguments like this.

```
int compile_single_invocation(OUTPUT_STREAM, invocation *inv,
    source_location *where_from, args_packet *mock_argsp, int within_resolver) {
    BEGIN_COMPILATION_MODE;
    int rv = compile_single_invocation_dash(OUT, inv, where_from, mock_argsp, within_resolver);
    END_COMPILATION_MODE;
    return rv;
}

§**5.** Phrases to decide a condition must compile to valid I6 conditions, which we need to ensure there are round brackets around.

⟨CSI - Start of phrase 5⟩ ≡

```
    switch (ph->type_data.manner_of_return) {
        case DECIDES_CONDITION_MOR:
            WRITE("(");
            break;
    }
```

This code is used in §4.

§**6.** CSI: Inline, the new criminal forensics show. Jack Corrizo, lonely but brilliant scene of crime officer, tells it like it is, and as serial killers stalk the troubled city of Inline, Missouri, ... Oh, very well: this is the code which turns an inline phrase definition into I6 code. That sounds like an elementary matter of copying it out, but we need to expand material in curly braces, according to what amounts to a mini-language. The exact definition of this mini-language was the subject of some speculation in the early days of the I7 Public Beta: but the exotic features it contains were never meant to be used anywhere except by the Standard Rules.

As the following shows, the inline definition is copied literally except for commands inside `{` and `}`, except that `{` followed by a space is treated as literal and not a command opening.

⟨CSI - Inline 6⟩ ≡

```
{
    char inline_definition[MAX_INLINE_DEFN_LENGTH];
    int j, tok, definition_length;
    ⟨CSI - I - Read inline definition 7⟩;
    definition_length = strlen(inline_definition);
    for (j=0; j<definition_length; j++) {
        if ((inline_definition[j] == '{') &&
            (inline_definition[j+1] != ' ') && (inline_definition[j+1] != '\t') &&
            (inline_definition[j+1] != '\n') && (inline_definition[j+1] != '|')) {
            char substitution[MAX_INLINE_DEFN_LENGTH];
            char command[MAX_INLINE_DEFN_LENGTH];
            char *extremal_property_name = NULL;
```

```
            int extremal_property_sign = 0;
            ⟨CSI - I - Parse braced command 8⟩;
            ⟨CSI - I - Obey substitutionless commands 9⟩;
            feed_into_lexer(substitution, FALSE, FALSE);
            ⟨CSI - I - Obey non-token substitutions 10⟩;
            tok = parse_name_local_to_inline_stack_frame(ph,
                lexer_feed_w1, lexer_feed_w2);
            if ((tok >= 0) && (tok < inv_get_number_tokens(inv))) {
                ⟨CSI - I - Obey token substitutions 11⟩;
            }
            ⟨CSI - I - Error in braced command 12⟩;
        } else {
            WRITE("%c", inline_definition[j]);
        }
    }
}
```

This code is used in §4.

§**7.** Extract the phrase's inline definition, and its return type.

```
⟨CSI - I - Read inline definition 7⟩ ≡
{
    int outcome_mor = ph_To_inline_read_outcome_mor(ph);
    if (outcome_mor != UNKNOWN) phrase_spec_specific_type = outcome_mor;
    ph_To_inline_write_definition(ph, inline_definition);
}
```

This code is used in §6.

§**8.** A general braced command can be any of the following.

```
{-command}
{some text}
{-annotation:some text}
{-annotation<property name:some text}
{-annotation>property name:some text}
```

We parse this with the command or annotation in `command`, the "some text" in `substitution`, and the property name (if given) in `extremal_property_name`.

```
⟨CSI - I - Parse braced command 8⟩ ≡
{
    int k;
    for (k=0; (k<MAX_INLINE_DEFN_LENGTH-1)&&(inline_definition[j+1+k] != '}'); k++)
        substitution[k] = inline_definition[j+1+k];
    j += k+1;
    substitution[k] = 0;
    command[0] = 0;
    if (substitution[0] == '-') {
        for (k=1; (substitution[k]) && (substitution[k] != ':'); k++)
            command[k-1] = substitution[k];
        command[k-1] = 0;
        if (substitution[k] == 0) substitution[0] = 0;
```

```
        else {
            int k2; k++;
            for (k2=k; substitution[k2]; k2++)
                substitution[k2-k] = substitution[k2];
            substitution[k2-k] = 0;
        }
    }
    for (k=0; command[k]; k++) {
        if (command[k] == '>') extremal_property_sign = 1;
        if (command[k] == '<') extremal_property_sign = -1;
        if (extremal_property_sign != 0) {
            command[k] = 0;
            extremal_property_name = command+k+1;
            break;
        }
    }
}
```

This code is used in §6.

§**9.** The raw commands, which have no text supplied. (Strictly speaking, the `label` and `next-label` commands do optionally take a substitution, but in almost all cases this is the empty text.)

⟨CSI - I - Obey substitutionless commands 9⟩ ≡

§**12.** Only meddling charlatans will ever see this message. And they deserve it.

⟨CSI - I - Error in braced command 12⟩ ≡

```
    sentence_problem(_P_(C12BadInlineExpansion),
        "when I expanded that command using its inline definition, "
        "I ran into an expansion written in braces { and } which "
        "was not one of the names of tokens from its specification",
        "so I don't know how to compile this. What you've defined "
        "here is not a phrase which will compile to an I6 "
        "routine, but rather a phrase which will compile 'inline' "
        "directly into the body of other routines: this happened "
        "because it was a 1-command definition, and that command "
        "was an I6 insertion. The ability to write inline phrases "
        "is really intended only for the Standard Rules and other "
        "low-level system extensions, and it is (intentionally) "
        "limited in its flexibility. A good rule of thumb is: if "
        "you can define a phrase without using I6 insertions, "
        "always do so.");
```

This code is used in §6.

§**13.** Compiling an invocation by a function call is simple:

⟨CSI - By function call 13⟩ ≡
```
{ int options_supplied = inv_get_phrase_options_bitmap(inv);
    kind_of_value *rp_kov = NULL;
    if (inv->phrase_options_invoked == NULL) options_supplied = -1;
    if (kov_uses_pointer_values(spec_get_kind_of_value(ph->type_data.return_type)))
        rp_kov = spec_get_kind_of_value(ph->type_data.return_type);
    compile_function_call(OUT,
        where_from, mock_argsp, FALSE, ph_get_I6_representation(ph),
        options_supplied, rp_kov, NULL, within_resolver);
}
```
This code is used in §4.

§**14.** Here we complete the I6 code for the invocation. Two crucial rules of I7 are contained here: the one which prints a new-line if we say text which ends with punctuation of the right kind, and the one which causes the routine to return `true` in the event of the "instead" keyword being used. The rest of this stuff is just tidying up.

⟨CSI - End of phrase 14⟩ ≡
```
    switch (ph->type_data.manner_of_return) {
        case DECIDES_CONDITION_MOR:
            WRITE(")");
            break;
        case DECIDES_NOTHING_MOR:
            if (ph->type_data.invoked_inline_not_as_call == FALSE)
                WRITE(";");
            if (inv_implies_newline(inv)) {
                if ((mock_argsp->args_count > 0)
                    && (spec_is_CONSTANT_of_kova(mock_argsp->args[0], TEXT_TY))
                    && (text_ending_sentence(
                        mock_argsp->args[0]->word_ref1)))
                    WRITE(" new_line;");
            }
            if (inv_test_flag(inv, INSTEAD_INVFLAG)) {
                WRITE(" rtrue;");
                phrase_spec_specific_type = DECIDES_NOTHING_AND_RETURNS_MOR;
            }
            if (singleton_block)
                WRITE(" }");
    }
```
This code is used in §4.

§15. Middle level: compile invocation blocks. The block is a sublist of the list of invocations in a SP, and it is marked here by the first entry in the sublist (`tref1`) and the first entry beyond the sublist (`tref2`), which is null if the sublist extends to the end of the list.

The block sublist will consist of at least one invocation, and all of these except possibly the last one will be "unproven" by the type-checking apparatus – that is, will not be safe to execute without run-time checking. We must execute exactly one invocation in the block – the first one which is found to be type-safe – or else produce a run-time error message.

It follows that there is only one case where no checking is needed: when the list consists of a single proven invocation. This we compile directly to the I6 stream. In all other cases, we compile a function call to a "resolver routine" to the I6 stream, delegating the choice to an external routine: and we will probably have to compile this routine, too, unless the decision on this block is one that we recognise from an earlier invocation block (in what may be another setting entirely).

```
STREAM resolve_f_struct;
STREAM *resolve_f = NULL;

void compile_invocation_block(OUTPUT_STREAM, specification *spec_found,
    int iref1, int iref2, int compiling_last_inv_group) {

    }
}
```

§**16.** The group is a sublist of a linked list of references, each of which points to an invocation. Here we determine the first and last invocations in the sublist, and their position numbers in the full list.

⟨CIB - Find group boundaries 16⟩ ≡
```
first_pos = iref1; last_pos = iref2 - 1; size = last_pos - first_pos + 1;
last_inv = NULL; first_inv = NULL;
INVOCATION_VARIABLE(latest_inv_found);
pos = 0;
LOOP_THROUGH_INVOCATION_LIST(latest_inv_found, spec_invocation_list(spec_found)) {
    if (pos == first_pos) first_inv = latest_inv_found;
    if (pos == last_pos) last_inv = latest_inv_found;
    pos++;
}
if ((first_pos<0) || (last_pos<0) || (last_pos < first_pos))
    internal_error("Bad positions in compile invocation block range");
if ((first_inv == NULL) || (last_inv == NULL))
    internal_error("Bad invs in compile invocation block range");
```
This code is used in §15.

§**17.** We get to here if the first invocation in the group is unproven, meaning that at compile time it was impossible to determine whether it was type-safe to execute. We must therefore compile code to determine this at run-time.

A "resolver routine" abstracts the choice to be made at run-time. Recall that out of all the invocations in the group, at most one is supposed to happen, and we have to choose which at run-time (or, if none happens, produce a run-time error). Each such decision is handled by a routine with a name like `Resolver_2`. (The suffix, here 2, is called the "ambiguity number".) We cache these routines because some decisions occur very commonly, and we don't want to compile more resolver routines than we have to.

The code we immediately compile, then, is a call to this resolver routine, which goes into the I6 stream. If the ambiguity is one that has been cached already, i.e., for which a resolver routine already exists, then that is all that we need to do; so we exit the CIB routine. Otherwise, we need to compile a new resolver routine: these are written serially to a file with handle `resolve_f`, which points to a temporary file created if and when needed.

Two points need to be remembered when compiling the function call, which looks the easiest thing but is not:

(i) The arguments used to call the resolver routine are always those tokens provided by the first invocation in the list. (The type-checker will not allow us to have a list of unproven invocations in which the individual entries have different, or a different number of, token values: so we could just as easily take the arguments from any of the invocations in the list – the result would be the same.)

(ii) All of this code has to be able to work recursively. It might be that the various tokens used as arguments to the resolver routine will themselves require resolution to evaluate. Because of this, we force the type-checker to sort out each of the arguments before beginning the resolver routine header; otherwise we might end up with messily interleaved resolver routines in the `resolve_f` file.

⟨CIB - Call and create resolver routine 17⟩ ≡
```
{
    int r = find_ambiguity_number(spec_found, first_pos, last_pos);

}
```

This code is used in §15.

§**18.** The structure of a resolver routine is simple: the header; then a list of I6 statements in the form "if run-time type checking works for this invocation, carry it out and return", one for each invocation in the group; then the footer.

Recall that the type-checker nulls out `token_check_to_do` fields as it proves them safe: therefore, the non-null ones left to us here are the ones we have to check.

We compile the invocation to one of the following forms, the first for unproven invocations, the second for proven ones (as the last in the list may well be):

`if (`...run-time-checking...`) { `...execute and return...`}`

...execute and return...

If the phrase invoked returns a value, we return that value as part of "execute and return"; if it is void, we perform it and return `true`. Either way, "...execute and return..." leaves the resolver routine if it is reached. Thus we can only fall through to subsequent invocations if the invocation was unproven and the run-time checking failed.

⟨CIB - Compile invocation as line in resolver routine 18⟩ ≡

```
{
    int i, condition_attached = FALSE;

if (condition_attached) STREAM_WRITE(resolve_f, " }");
STREAM_WRITE(resolve_f, "\n");
END_COMPILATION_MODE;
}
```

This code is used in §15.

§**19.** The much simpler alternative, if no resolver routine is being made:

⟨CIB - Compile invocation directly to I6 stream 19⟩ ≡

```
returned_in_manner = compile_single_invocation(OUT,
    inv, &(lw_array[spec_found->word_ref1].lw_source), &mock_argsp, FALSE);
```

This code is used in §15.

§**20.** The resolver routine footer can only be reached if all of the invocations fail run-time checking, so unless we can prove that the last invocation will always happen, we need to print a run-time error message if execution gets there.

⟨CIB - Finish resolver routine 20⟩ ≡

```
    if (inv_test_flag(last_inv, UNPROVEN_INVFLAG)) {
        LOGIF(INVOCATIONS, "Final inv unproven, so resolver falls to RTE\n");
        STREAM_WRITE(resolve_f, "ArgumentTypeFailed(filename, line);\n");
    }
    STREAM_WRITE(resolve_f, "  rfalse; ];\n");
```

This code is used in §15.

§**21.** Of course, we also have to merge these resolver routines into the main code, once all passion is spent.

```
void compile_resolver_routines(OUTPUT_STREAM) {
    if (resolve_f) {
        STREAM_COPY(OUT, resolve_f);
        STREAM_CLOSE(resolve_f);
        resolve_f = NULL;
    }
}
```

The function compile_resolver_routines is invoked by a command in a `.i6t` template file.

§**22. Top level: compile all the invocations of a phrase.** We do a little initialisation if the list turns out to be a set of things, one said after another, because special rules apply to "say": but otherwise we pretty much simply find each group in turn and pass it down to the middle level.

define MAX_COMPLEX_SAY_DEPTH 32 *and it would be terrible coding style to approach this*

```

            "there are only a small number of doors and they can be put in order "
            "of creation. But you can't 'repeat with N running through numbers' "
            "because numbers are without end.");
    spec_convert_docket_to_proposition(spec);
    if (spec_get_proposition(spec)) {
        WRITE("if (");
```

```
        compile_test_of_proposition(OUT, localv, spec_get_proposition(spec));
        WRITE(") ");
    }
    END_COMPILATION_MODE;
}
```

Runtime Ambiguities 12/ambig

Purpose

To keep track of runtime ambiguities likely to arise, classifying them into equivalent questions, in order to minimise the amount of run-time checking code which will be needed.

Definitions

¶1. When runtime ambiguities are allowed to persist, special resolution routines must be compiled to sort them out. The following structure caches details of previous similar resolutions, to minimise the quantity of code produced, and a global variable counts distinct "resolver routines" as they are compiled.

```
define LARGEST_CACHED_INVOCATION_GROUP 16                    larger groups are legal, but not cached

typedef struct runtime_ambiguity {
    int resolver_routine_number;                              N such that this caches Resolver_N
    int no_invs;                                              number of invocations in group
    invocation invs[LARGEST_CACHED_INVOCATION_GROUP];         and what they are
    MEMORY_MANAGEMENT
} runtime_ambiguity;

int no_runtime_ambiguities = 0;
```

The structure runtime_ambiguity is private to this section.

---

§**1.** We are given an invocation group for a given SP, and must return (i) an ID number for the resolver routine needed to handle this invocation group, and also (ii) whether the routine has already been compiled or not. It would be valid to simply always return with a new ID number, always requiring a resolver routine to be newly compiled: but it would be inefficient. So we cache all previous decisions on groups of size 16 or fewer (it is vanishingly unlikely that a duplicate will ever occur on two different invocation groups of size 16 or more, so this is no real loss).

We return two pieces of information, which we compile into a single integer: if the routine returns a non-negative number, the routine already exists and this is its ID number; if it returns a negative number X, then the routine does not already exist and should be created with new ID number $-X-1$. In the event of an error, we return the following non-value.

```
define NONDETERMINABLE -1000000

int find_ambiguity_number(specification *spec_found, int first_pos, int last_pos) {
    int group_size = last_pos - first_pos + 1;
    int k, p, cached;
    runtime_ambiguity *rta;
    LOGIF(INVOCATIONS, "Finding ambiguity number for $S group (invs %d to %d)\n",
        spec_found, first_pos, last_pos);
    ⟨FAN - Validate group as determinable 2⟩;
    cached = FALSE;
    if (group_size < LARGEST_CACHED_INVOCATION_GROUP) {
        ⟨FAN - Seek in cache 3⟩;
        cached = TRUE;
        ⟨FAN - Place in cache 4⟩;
    }
    LOGIF(INVOCATIONS, "Allocating new runtime ambiguity number %d (%s)\n",
        no_runtime_ambiguities, (cached)?"cached":"uncached");
```

```
    no_runtime_ambiguities++;
    return -no_runtime_ambiguities;
}
```

The function find_ambiguity_number is called from 12/cinv.

§**2.** We look for certain bad cases here, returning "nondeterminable" if we find them. This enables routines higher up to generate a problem message, since such bad cases occur only due to errors in the source text.

⟨FAN - Validate group as determinable 2⟩ ≡

```
    INVOCATION_VARIABLE(inv1);
    LOOP_THROUGH_PART_OF_INVOCATION_LIST(inv1, spec_invocation_list(spec_found), p, first_pos, group_size)
{
        LOGIF(INVOCATIONS, "Validating %d: $e\n", p, inv1);
        phrase *ph = inv1->phrase_invoked;
        if (ph == NULL) continue;
        if (phtd_safe_for_runtime_resolution(&(ph->type_data)) == FALSE) {
            LOGIF(INVOCATIONS, "Impossible: not determinable at runtime\n");
            return NONDETERMINABLE;
        }
        for (k=0; k<inv_get_number_tokens(inv1); k++) {
            specification *spec1 = inv_get_token_check_to_do(inv1, k);
            if (spec_get_storage_form(spec1) == PROPERTY_VALUE_SPC) {
                LOGIF(INVOCATIONS, "Impossible: not determinable at runtime\n");
                return NONDETERMINABLE;
            }
        }
    }
```

This code is used in §1.

§**3.** For each cached group of the same length, we compare invocations. If we can find a perfect match, we return its resolver routine number, always a non-negative integer.

⟨FAN - Seek in cache 3⟩ ≡

```
    LOOP_OVER(rta, runtime_ambiguity) {
        if (group_size != rta->no_invs) continue;
        INVOCATION_VARIABLE(inv1);
        int j = 0;
        LOOP_THROUGH_PART_OF_INVOCATION_LIST(inv1, spec_invocation_list(spec_found), p, first_pos, group_size)
{
            invocation *inv2 = &(rta->invs[j++]);
            if (inv1->phrase_invoked != inv2->phrase_invoked)
                goto NotThisAmbiguity;
            if (inv_get_phrase_options_bitmap(inv1) != inv_get_phrase_options_bitmap(inv2))
                goto NotThisAmbiguity;
            for (k=0; k<inv_get_number_tokens(inv1); k++) {
                specification *spec1 = inv_get_token_check_to_do(inv1, k);
                specification *spec2 = inv_get_token_check_to_do(inv2, k);
                if ((spec1 == NULL) && (spec2 != NULL)) goto NotThisAmbiguity;
                if ((spec1 != NULL) && (spec2 == NULL)) goto NotThisAmbiguity;
            }
        }
        LOGIF(INVOCATIONS, "Found in cache of runtime ambiguities: %d\n",
```

```
            rta->resolver_routine_number);
        return rta->resolver_routine_number;
        NotThisAmbiguity: ;
    }
```

This code is used in §1.

§**4.** If it hasn't been found, then we will be returning `no_runtime_ambiguities` as the ID number for the resolver routine; we cache this particular invocation group for future use, assigning it to this ID number.

⟨FAN - Place in cache 4⟩ ≡

```
    rta = CREATE(runtime_ambiguity);
    rta->resolver_routine_number = no_runtime_ambiguities;
    rta->no_invs = group_size;
    int j = 0;
    INVOCATION_VARIABLE(inv1);
    LOOP_THROUGH_PART_OF_INVOCATION_LIST(inv1, spec_invocation_list(spec_found), p, first_pos, group_size)
{
        rta->invs[j++] = *inv1;
    }
```

This code is used in §1.

Compile Phrases 12/cph

Purpose

For each phrase whose declaration involves a list of expressions to be evaluated in void context – that is, whose declaration is not an inline piece of I6 – we compile a suitable I6 routine. We also provide some utilities for other sections of NI needing to compile I6 routines not derived directly from phrases.

12/cph.§3 A whole little compiler

Definitions

¶1. We need to keep track of the current phrase being compiled since it provides the local scope for the names of local variables and the like. Note that one phrase definition cannot contain another, so there is never any need to recursively compile phrases.

```
phrase *phrase_being_compiled = NULL;                    phrase whose definition is being compiled
```

```
void code_indent(OUTPUT_STREAM, int indent_level) {
    while (indent_level-- > 0) WRITE("    ");
}
void code_indent_to_block_level(OUTPUT_STREAM) {
    int indent_level = current_block_level() + 2;
    code_indent(OUT, indent_level);
}
void compile_i6_divider_comment(OUTPUT_STREAM) {
    WRITE("! ------------------------------------------------"
                "------------------------------------------------\n");
}
```

The function code_indent is called from 12/phrcd and 12/rb.

The function compile_i6_divider_comment is called from 12/br and 12/rb.

§**1.** We have a problem in that we don't know how many locals a routine we will need until later, but we have to declare them in the routine's header. So we cheat, by compiling the routine code to a temporary file, then writing the header, then copying over the code.

```
STREAM *of_holder;
STREAM temporary_of_struct; STREAM *temporary_of = &temporary_of_struct;
STREAM *begin_compiling_phrase(OUTPUT_STREAM) {
    if (STREAM_OPEN_IN_MEMORY(temporary_of) == FALSE)
        fatal_error("Out of memory: can't allocate for phrase definition");
    of_holder = OUT; OUT = temporary_of;
    return OUT;
}
STREAM *write_routine_header(void) {
    return of_holder;
}
void copy_compiled_phrase(void) {
    ph_stack_frame *phsf = current_stack_frame();
    phsf_compile_i6_local_declarations(phsf, of_holder);
    STREAM_COPY(of_holder, temporary_of);
    STREAM_CLOSE(temporary_of);
}
```

The function begin_compiling_phrase is called from 5/aph, 9/scene, 10/str, 11/los, 12/phsf and 13/gl.
The function write_routine_header is called from 5/aph, 9/scene, 10/str, 11/los, 12/phsf and 13/gl.
The function copy_compiled_phrase is called from 5/aph, 9/scene, 10/str, 11/los, 12/phsf and 13/gl.

§**2.** The following routines have no effect on the functionality of the I6 compiled: they generate either comments helping to show how the I6 matches the original I7 source text, or else debugging print statements to the same effect, so that the testing command RULES ALL will be able to display to the user what is going on at run-time.

```
int statement_count;
void compile_I6_text_for_COMMAND_node(OUTPUT_STREAM, parse_node *p,
    int write_debugging_matter) {
    int j, out_loud = TRUE;
    if ((write_debugging_matter == FALSE) || [[p == end/else/otherwise ***]] ||
        (pn_int_annotation(p, suppress_debug_text_ANNOT)))
        out_loud = FALSE;
    out_loud = FALSE;
    if (pn_get_node_type(p) != COMMAND_NT) internal_error("not a COMMAND node");
    code_indent_to_block_level(OUT);
    if (out_loud == FALSE) WRITE("! ");
    if (out_loud) {
        WRITE("  #ifndef MEMORY_ECONOMY; ");
        WRITE("if (debug_rules>1) print \"  ");
    }
    WRITE("[%d: ", statement_count++);
    for (j=p->word_ref1; j<=p->word_ref2; j++) {
        isn_compile_string(OUT, lw_array[j].lw_text, ISN_FLATTEN_NEWLINES);
        if (j<p->word_ref2) WRITE(" ");
    }
    if (out_loud)
        WRITE("]^\"; #endif;\n");
    else
        WRITE("]\n");
    if ((out_loud) && (p->next) && [[p->next == otherwise/else ***]])
        compile_I6_text_for_COMMAND_node(OUT, p->next, TRUE);
}
void compile_more_I6_text_for_COMMAND_node(OUTPUT_STREAM, parse_node *p,
    int write_debugging_matter) {
    if (write_debugging_matter) {
        if [[p == repeat ***]] {
            int lnum;
            code_indent_to_block_level(OUT);
            if (memory_economy_in_force == FALSE) {
                WRITE("  if (debug_rules>1) print \"  ");
                lnum = local_whose_scope_is_block(current_block_level()-1);
                if (lnum >= 0) describe_repetition_local(OUT, lnum);
                else WRITE("[repetition through row \", ct_1, \"]^\";\n");
            }
        }
        if [[p == end repeat]] {
            code_indent_to_block_level(OUT);
```

```
            if (memory_economy_in_force == FALSE) {
                WRITE("  if (debug_rules>1) print \"  ");
                WRITE("[%d: end repeat]^\";\n", statement_count-1);
            }
        }
    }
}
void compile_phrase(OUTPUT_STREAM, phrase *ph, stacked_variable_owner_list *legible) {
    parse_node *p;
    heading *definition_area;
    extension_file *definition_extension;
    int write_debugging_matter = TRUE;
    if ((ph->declaration_node == NULL) ||
        (pn_get_node_type(ph->declaration_node) != ROUTINE_NT) ||
        (ph->declaration_node->word_ref1 < 0))
        internal_error("tried to compile phrase with bad ROUTINE node");
    definition_area = heading_of(lw_array[ph->declaration_node->word_ref1].lw_source);
    definition_extension = hd_get_extension_containing(definition_area);
    phrase_being_compiled = ph;
    phsf_set_stvol(&(ph->stack_frame), legible);
    if (definition_extension) {
        write_debugging_matter = FALSE;
        ef_write_I6_comment_describing(definition_extension, OUT);
    }
    phud_write_I6_comment_describing(&(ph->usage_data), OUT);
    OUT = begin_compiling_phrase(OUT);
    begin_code_blocks();
    LOGIF(PHRASE_COMPILATION, "Compiling phrase:\n$T", ph->declaration_node);
    current_sentence = ph->declaration_node;
    phrcd_compile_test_head(&(ph->runtime_context_data), OUT,
        ph_get_I6_representation(ph), ph);
    statement_count = 1;
    for (p = ph->declaration_node->down; p; p = p->next) {
        current_sentence = p;
        code_indent_to_block_level(OUT);
        WRITE("! phrase %d\n", statement_count);
        compile_I6_text_for_COMMAND_node(OUT, p, write_debugging_matter);
        code_indent_to_block_level(OUT);
        compile_To_phrase(OUT, p->word_ref1, p->word_ref2);
        WRITE("\n");
        compile_more_I6_text_for_COMMAND_node(OUT, p, write_debugging_matter);
        STREAM_FLUSH(dl);                                    In case of any accident
        finish_this_session_of_parsing();
    }
    end_code_blocks();
    phrcd_compile_test_tail(&(ph->runtime_context_data), OUT,
        ph_get_I6_representation(ph), ph);
    OUT = write_routine_header();
    STREAM_WRITE(of_holder, "[ %s ", ph_get_I6_representation(ph));
```

```
    copy_compiled_phrase();
    code_indent(OUT, 1);
    phtd_compile_default_return(OUT, &(phrase_being_compiled->type_data),
        &(ph->runtime_context_data));
    WRITE("\n];\n");
    phrase_being_compiled = NULL;
    finish_this_session_of_parsing();
}
```

The function compile_phrase is called from 12/ph.

§**3. A whole little compiler.** This routine sits at the summit of a mountain of code: it takes a use of a phrase through every stage from raw text to final compiled code.

```
specification *match_To_phrase = NULL;
void compile_To_phrase(OUTPUT_STREAM, int w1, int w2) {
    if (match_To_phrase == NULL) match_To_phrase = new_COMMAND_spec();
    int initial_problem_count = problem_count;
    LOGIF(EXPRESSIONS, "\n-- -- Evaluating <$W> -- --\n(a) Parsing:\n", w1, w2);
    specification *spec_found = parse_expression(w1, w2, VOID_EXPCON);
    if (initial_problem_count == problem_count) {
        LOGIF(EXPRESSIONS, "(b) Type checking as $S:\n$X", match_To_phrase, spec_found);
        typecheck(spec_found, match_To_phrase);
    }
    if (initial_problem_count == problem_count) {
        LOGIF(EXPRESSIONS, "(c) Compilation:\n");
        if (spec_has_invocation_list(spec_found))
            LOGIF(INVOCATIONS, "Invocation list to be compiled:\n$E\n",
                spec_invocation_list(spec_found));
        spec_compile(OUT, spec_found);
    }
    if (initial_problem_count == problem_count) {
        LOGIF(EXPRESSIONS, "-- -- Completed -- --\n");
    } else {
        LOGIF(EXPRESSIONS, "-- -- Failed -- --\n");
    }
}
```

The function compile_To_phrase is called from 10/str.

To Phrases 12/toph

Purpose

The first of four ways phrases are invoked: in the definitions of other phrases, and in I7 expressions and conditions. Here a phrase is used much as a function would be used in a C-like language.

12/toph.§3-5 Logical priority of To phrases; §6 Registering and compiling To phrases; §7 Phrase option parsing

---

§**1.** Some "To..." phrases have a body consisting of a list of invocations of other "to..." phrases, but others have inline definitions in terms of I6 code. The following routine accesses this definition:

```
void ph_To_inline_write_definition(phrase *ph, char *to) {
    if (ph->inline_wn < 0)
        internal_error("tried to access inline definition of non-inline phrase");
    strcpy(to, lw_array[ph->inline_wn].lw_text);
}
```

The function ph_To_inline_write_definition is called from 12/cinv.

§**2.** Inline phrase outcomes are one of the oldest type-checking features in NI, but they fell into abeyance due to a bug and also due to confusion about the right way to classify To phrases, so that between about 3Kxx and 4Sxx they did nothing. They now work, though. The idea is that certain inline definitions can mark themselves to be included only in To phrases of the right sort: it makes no sense to respond "yes" to a phrase "To decide what number is...", for instance. The following routine looks at the tail of the inline definition to parse the appropriate phrase type.

This syntax is intentionally undocumented, and is reserved for use by the Standard Rules only: hence the internal error rather than problem message for cases where it's misphrased.

```
int ph_To_inline_read_outcome_mor(phrase *ph) {
    parse_node *p = ph->declaration_node->down;
    int w1, w2;
    if (p == NULL)
        internal_error("tried to access inline definition of phrase with no body");
    if (ph->inline_wn < 0)
        internal_error("tried to access inline definition of non-inline phrase");
    [[w1, w2 <-- p]];
    LOGIF(INVOCATIONS, "form of inline: $W\n", w1, w2);
    if (w2 == w1+1) return UNKNOWN;
    w1 += 2;
    if [[w1, w2 == DASH in to only]] return DECIDES_NOTHING_MOR;
    if [[w1, w2 == DASH in to decide if only]] return DECIDES_CONDITION_MOR;
    if [[w1, w2 == DASH in to decide only]] return DECIDES_VALUE_MOR;
    LOG("Tail: $W\n", w1, w2);
    internal_error("unknown inline definition tail");
    return UNKNOWN;
}
```

The function ph_To_inline_read_outcome_mor is called from 12/cinv.

§**3. Logical priority of To phrases.** "To" phrases are insertion-sorted, as they are defined, into a linked list held in logical priority order. This essentially means that two lexically indistinguishable phrases (e.g., "admire (OC - an open container)" and "admire (C - a container)") are placed such that the more specific, in type-checking terms, comes first (the open container case being the more specific). The purpose of this list is to ensure that excerpt meanings for phrase definitions are registered in logical priority order, because the excerpt parser prefers earlier registrations to later ones in case of ambiguity.

Note that the following sort algorithm affects only "to..." phrases, and therefore has no effect on rule ordering within rulebooks.

§**4.** The system for deciding which of two phrases is logically prior, if either is. This is not quite compatible with the other comparison routines in NI (for comparing action patterns, SPs, etc.) because it returns a wider variety of values:

```
define BEFORE_PH -3
define SUBSCHEMA_PH -1
define EQUAL_PH 0
define SUPERSCHEMA_PH 1
define INCOMPARABLE_PH 2
define AFTER_PH 3

int ph_To_compare(phrase *ph1, phrase *ph2) {
    int r = phtd_comparison(&(ph1->type_data), &(ph2->type_data));
    if (dl_this(PHRASE_COMPARISONS_DA)) {
        char tell_debug[1024];
        ph_write_HTML_representation(ph1, tell_debug);
        LOG("Phrase comparison <%s>\n  ", tell_debug);
        switch(r) {
            case INCOMPARABLE_PH: LOG("~~"); break;
            case SUBSCHEMA_PH: LOG("<="); break;
            case SUPERSCHEMA_PH: LOG(">="); break;
            case EQUAL_PH: LOG("=="); break;
            case BEFORE_PH: LOG("<"); break;
            case AFTER_PH: LOG(">"); break;
        }
        ph_write_HTML_representation(ph2, tell_debug);
        LOG(" <%s>\n", tell_debug);
    }
    return r;
}
```

§**5.** The following routine takes a phrase and makes it officially a To phrase, which in particular means adding it to the list of To phrases in logical order.

```
struct phrase *first_in_logical_order = NULL;
void ph_To_make(phrase *ph) {
    phrase *previous_phrase = NULL;
    phrase *current_phrase = first_in_logical_order;
    sprintf(ph_get_I6_representation(ph), "PHR_%d", ph->allocation_id);
    if (first_in_logical_order == NULL) { first_in_logical_order = ph; return; }
    while ((current_phrase != NULL) &&
            (ph_To_compare(ph, current_phrase) >= 0)) {
        previous_phrase = current_phrase;
        current_phrase = current_phrase->next_in_logical_order;
    }
    if (previous_phrase == NULL) {
        ph->next_in_logical_order = first_in_logical_order;
        first_in_logical_order = ph;
        return;
    }
    previous_phrase->next_in_logical_order = ph;
    ph->next_in_logical_order = current_phrase;
}
```

The function ph_To_make is called from 12/ph.

§**6. Registering and compiling To phrases.** These are the only places where the logical precedence list is directly used, but registration of the excerpts in precedence order ensures that this ordering has a profound effect on expression parsing throughout NI.

Compilation in precedence order is by contrast done for purely cosmetic reasons, that is, to make the I6 source code more legible.

```
void ph_To_register_all(void) {
    phrase *ph;
    int c = 0;
    for (ph = first_in_logical_order; ph; ph = ph->next_in_logical_order) {
        current_sentence = ph->declaration_node;
        phtd_register_excerpt(&(ph->type_data), ph);
        ph->sequence_count = c++;
    }
}
int ph_sequence_count(phrase *ph) {
    if (ph == NULL) internal_error("Sought sequence count for null phrase");
    if (ph->sequence_count == -1) {
        log_phrase(ph);
        internal_error("Sequence count not ready");
    }
    return ph->sequence_count;
}
void ph_To_compile_all(OUTPUT_STREAM, int *i, int max_i) {
    phrase *ph;

Adjectival Definitions 12/def

Purpose

The second of four ways phrases are invoked: as definitions of adjectives which can be used as unary predicates in the calculus. (And we also look after adjectives arising from I6 or I7 conditions, and from I6 routines.)

Template interpreter commands

```
0   {-callv:traverse_for_adjective_definitions}
```

Definitions

¶1. A typical example would be:

Definition: A container is significant if it contains a clue.

Here the domain of the definition is "container", and the meaning assigned to "significant" is an I7 condition; but we can also make it an I6 condition, or (a tidier way to express the same thing) delegate it to an I6 routine. Phrases enter only when we define an adjective with an explicit, though nameless, I7 rule:

Definition: A container (called the sac) is significant: if the sac contains a clue, decide yes; ...

That makes four distinct kinds of adjective, but all share the following structure to hold details of their specific meanings:

```
typedef struct definition {
    struct parse_node *definition_node;          current sentence: where the word "Definition" is
    struct parse_node *node;                                  where the actual definition is
    int format;                          +1 to go by condition, -1 to negate it, 0 to use routine
    int condition_w1, condition_w2;                text of condition to match, if +1 or -1
    int domain_calling_w1, domain_calling_w2;        what if anything the term is called
    struct adjective_meaning *am_of_def;                          which adjective meaning
    MEMORY_MANAGEMENT
} definition;
```

The structure definition is private to this section.

```

Timed Phrases 12/tiph

Purpose

The third of four ways phrases are invoked: as timed events, which need no special NI data structure and are simply compiled into a pair of timetable I6 arrays to be processed at run-time.

Definitions

¶1. The timing of an event records the time at which a phrase should spontaneously happen. This is ordinarily a time value, in minutes from 12 midnight, for a phrase happening at a specific time – for instance, one defined as "At 9:00 AM: ..." But two values are special:

define NOT_A_TIMED_EVENT -1 *as for the vast majority of phrases*
define NO_FIXED_TIME -2 *for phrases like "When the clock strikes: ..."*

---

§**1.** Timed events are stored in two simple arrays, processed by run-time code.

```
void tiph_compile_TimedEventsTable_array(OUTPUT_STREAM) {
    phrase *ph;
    int i, t, when_count = 0;
    WRITE("Array TimedEventsTable table");
    LOOP_OVER(ph, phrase) {
        t = phud_get_timing_of_event(&(ph->usage_data));
        if (t == NOT_A_TIMED_EVENT) continue;
        if (t == NO_FIXED_TIME) when_count++;
        else WRITE(" %s", ph_get_I6_representation(ph));
    }
    for (i=0; i<when_count+1; i++) WRITE(" 0 0");
    WRITE(";\n");
}
void tiph_compile_TimedEventTimesTable_array(OUTPUT_STREAM) {
    phrase *ph;
    int i, t, when_count = 0;
    WRITE("Array TimedEventTimesTable table");
    LOOP_OVER(ph, phrase) {
        t = phud_get_timing_of_event(&(ph->usage_data));
        if (t == NOT_A_TIMED_EVENT) continue;
        if (t == NO_FIXED_TIME) when_count++;
        else WRITE(" %d", t);
    }
    for (i=0; i<when_count+1; i++) WRITE(" 0 0");
    WRITE(";\n");
}
void tiph_index_rules(void) {
    phrase *ph;
    int t, when_count = 0, tt_count = 0;
    LOOP_OVER(ph, phrase) {
        t = phud_get_timing_of_event(&(ph->usage_data));
        if (t == NOT_A_TIMED_EVENT) continue;
        if (t == NO_FIXED_TIME) {
            if (when_count == 0)
```

```
                INDEX("<p><i>Events with no specific time</i><br>");
            when_count++;
            INDEX("        ");
            phud_print_preamble_to(&(ph->usage_data), ifl);
            if ((ph->declaration_node != NULL) &&
                (ph->declaration_node->word_ref1 >= 0))
                index_link(lw_array[ph->declaration_node->word_ref1].lw_source);
            INDEX("<br>");
        }
    }
    LOOP_OVER(ph, phrase) {
        t = phud_get_timing_of_event(&(ph->usage_data));
        if (t == NOT_A_TIMED_EVENT) continue;
        if (t != NO_FIXED_TIME) {
            if (tt_count == 0)
                INDEX("<p><i>Timetable</i><br>");
            tt_count++;
            INDEX("        ");
            phud_print_preamble_to(&(ph->usage_data), ifl);
            if ((ph->declaration_node != NULL) &&
                (ph->declaration_node->word_ref1 >= 0))
                index_link(lw_array[ph->declaration_node->word_ref1].lw_source);
            INDEX("<br>");
        }
    }
    INDEX("<p>");
}
```

Rules 12/br

Purpose

The fourth of four ways phrases are invoked: as rules capable of being placed in rulebooks. Each such phrase is pointed to by one or more `booked_rule` structures, which are analogous to looseleaf pages for use in ring-binders: a page can either be left looseleaf, or can be bound into a single rulebook. NI requires that phrases be able to belong to multiple rulebooks, and this is achieved by creating a different BR for each such membership. Here we create and manage both individual BRs and linked lists of BRs in logical specificity order.

12/br.§4 Variables accessible from here; §5 Placing primary BRs into rulebooks; §6 Run-time representation; §7 Specificity of rules; §8 Printing rule names at run time; §9-10 Lists of booked rules; §11 Compilation and other serial operations on lists

---

Definitions

¶1. A booked rule is a wrapper structure: it's a pointer to a phrase together with some cross-references to make compilation and error message production easier. We indirect through booked rules, rather than pointing directly to phrases, not only for this convenience but also to ensure that the same phrase may be booked into several rulebooks at once.

Booked rules are also used to keep track of rule names early in NI's run. NI basically sorts out the data structures first, then attends to the rules, but this goes awry if the data structures – tables, for instance – include references to specific rules by name, thus using them as data. Such rules are therefore "predeclared", a process which really only records their names, early in NI's run. (For similar timing-of-parsing reasons we also record the usage details of the rule from its header, even though this eventually just duplicates what will appear in the relevant `phrase` structure.)

The field `I6_value_of_rule` is generated by compiled a `VALUE/RULE` SP with this booked rule as its reference, and copying the resultant I6 code into the field's text. We need this so that we can be certain of the I6 value to compare against when we need this rule as a constant in the I6 code.

```
typedef struct booked_rule {
    struct booked_rule *next_rule;                          linked list of entries in rulebook
    int next_rule_specificity;                              1 more specific than following, 0 equal, −1 less
    char *next_rule_specificity_law;                        description of reason
    char *next_rule_specificity_lawname;                    name of Law used to sort
    struct phrase *the_rule;                                the rule being booked
    int placement;                                          one of three placement values
    int primary_booking;                                    TRUE if this results from the main preamble booking
    int predeclared;                                        as a name with value not known?
    int word_ref1, word_ref2;                               text of this predeclared name
    int italicised_index_text_w1, italicised_index_text_w2; when indexing a rulebook
    int marked_for_anyone;
    struct stacked_variable_owner_list *listed_stv_owners;  making vars visible here
    char I6_value_of_rule[32];                              an I6 identifier, something like "R_341"
    MEMORY_MANAGEMENT
} booked_rule;
```

The structure booked_rule is private to this section.

¶2. When booked rules are gathered into linked lists of booked rules, they are positioned using "placements". Ordinarily they go somewhere in the middle, but declarations are allowed to specify that they must occur at the front or back, e.g.:

The first reaching inside rule: ...

The `owning_rulebook_placement` field is therefore always one of the following three values:

```
define MIDDLE_PLACEMENT 0                    most rules are somewhere in the middle
define FIRST_PLACEMENT 1
define LAST_PLACEMENT 2
```

¶3. We specify the way we want to add a BR to a list of BRs using the following enumerated values, which handle requirements like "before the awkward noises rule".

```
define NO_SIDE -2                                              a dummy value
define BEFORE_SIDE -1                                          before a reference BR
define IN_SIDE 0                                               without reference to any other BR
define AFTER_SIDE 1                                            after a reference BR
define INSTEAD_SIDE 2                                          in place of reference BR
```

---

§**1.** Booked rules can be created either from an I7 `phrase`, possibly initially `NULL` for a predeclared rule; or from the name of an I6 routine in the I6 library, in which case no I7 `phrase` is needed since the compiled form of the rule is already available.

```
booked_rule *br_new(phrase *ph) {
    booked_rule *br = CREATE(booked_rule);
    br->the_rule = ph;
    br->I6_value_of_rule[0] = 0;
    br->word_ref1 = -1;
    br->word_ref2 = -1;
    br->italicised_index_text_w1 = -1;
    br->italicised_index_text_w2 = -1;
    br->predeclared = FALSE;
    br->primary_booking = FALSE;
    br->next_rule_specificity = 0;
    br->next_rule_specificity_law = NULL;
    br->next_rule_specificity_lawname = NULL;
    br->listed_stv_owners = NULL;
    br->marked_for_anyone = FALSE;
    br->next_rule = NULL;
    br->placement = MIDDLE_PLACEMENT;
    return br;
}
booked_rule *new_br_from_i6(int w1, int w2, int i6_wn, int copy_flag) {
    booked_rule *br = br_new(NULL);
    if (copy_flag) {
        booked_rule *br2 = br_by_name(w1, w2);
        if (br2) br_copy(br, br2);
        else sentence_problem(_P_(BelievedImpossible),          there is no sensible way to test this
            "the concise action syntax of the Standard Rules has gone wrong",
            "which suggests that perhaps you are tampering with the very "
```

```
            "forces of creation. Fool! Know ye not the perils that await "
            "the unwary?");
    } else {
        if (i6_wn < 0) internal_error("no such rule name text");
        br_set_name(br, w1, w2);
        strcpy(br->I6_value_of_rule, lw_array[i6_wn].lw_text);
        LOGIF(LIBRARY_RULES, "New library rule: $b = %s\n",
            br, br->I6_value_of_rule);
    }
    return br;
}
void log_booked_rule(booked_rule *br) {
    if (br == NULL) { LOG("BR:<null-booked-rule>"); return; }
    LOG("BR%d", br->allocation_id);
    if (br->predeclared) LOG("p");

        case MIDDLE_PLACEMENT: LOG("m"); break;
        case FIRST_PLACEMENT: LOG("f"); break;
        case LAST_PLACEMENT: LOG("l"); break;
        default: LOG("?"); break;
    }
    if (br->the_rule) LOG("[$R]", br->the_rule); else LOG("[-]");
}
```

The function br_new is called from 12/phud and 12/rps.
The function new_br_from_i6 is called from 12/cs.
The function log_booked_rule is called from 2/dl.

§**2.** We cannot copy a br simply by writing, say, `*to = *from` because this would also copy the hidden linked list references generated by the memory manager, and because we need to avoid similar duplication of the rulebook linked list placements, too. So we copy each element over by hand.

```
void br_copy(booked_rule *to, booked_rule *from) {
    to->the_rule = from->the_rule;
    strcpy(to->I6_value_of_rule, from->I6_value_of_rule);
    to->word_ref1 = from->word_ref1;
    to->word_ref2 = from->word_ref2;
    to->italicised_index_text_w1 = from->italicised_index_text_w1;
    to->italicised_index_text_w2 = from->italicised_index_text_w2;
    to->predeclared = from->predeclared;
    to->listed_stv_owners = stvol_append(NULL, from->listed_stv_owners);
    to->primary_booking = FALSE;                                    a copy cannot also be primary
    to->next_rule = NULL;
    to->placement = MIDDLE_PLACEMENT;
}
```

The function br_copy is called from 12/rps.

§**3.** Access to miscellaneous elements of the BR structure.

```
void br_set_name(booked_rule *br, int w1, int w2) {
    br->word_ref1 = w1;
    br->word_ref2 = w2;

The function br_acquire_action_variables is called from 12/rb.

§5. Placing primary BRs into rulebooks. Any BR marked as being the primary BR arising from a phrase is here officially placed into the rulebook it was declared as belonging to. Note that non-primary BRs (those arising, for instance, from declarations that a given rule name corresponds to a given I6 library routine name) are left alone.

Rules are insertion-sorted into rulebooks in `LOOP_OVER` order, which coincides with declaration order. This is important because it is creation order which the rule-sorting code falls back on when it can see no other justification for placing one rule either side of another.

```
void br_add_rules_to_rulebooks(void) {
    booked_rule *br;
    LOOP_OVER(br, booked_rule)
        if (br->primary_booking) {
            phrase *ph = br->the_rule;
            current_sentence = ph->declaration_node;
            phud_place_in_rulebook(&(ph->usage_data), br);
        }
}
```

The function br_add_rules_to_rulebooks is called from 12/cs.

§**6. Run-time representation.** In I6 code, a rule is compiled to the name of the routine implementing it, an I6 value of metaclass `Routine`. Note that two different BRs which point to the same `phrase` (or, though this is less likely, that provide two different I7 name aliases for the same I6 library routine) will compile to the same I6 value. This is essential, as it ensures that a phrase can indeed be used as a rule in more than one rulebook.

Note that a predeclared rule will be created with the I6 identifier `BR_21`, say, but will later (when phrase creation catches up) pick up a name like `R_306`. For consistency, these values must be equal in I6, and we ensure this by compiling I6 constant declarations such as:

```
Constant BR_21 = R_306;
```

```
void br_compile(OUTPUT_STREAM, booked_rule *br) {
    if (br->the_rule)
        WRITE("%s", ph_get_I6_representation(br->the_rule));
    else {
        if (br->I6_value_of_rule[0])
            WRITE("%s", br->I6_value_of_rule);
        else internal_error("tried to compile nameless booked rule");
        WRITE("RB    }
}
```

```
void br_resolve_predeclared_booked_rules(OUTPUT_STREAM) {
    booked_rule *br;
    LOOP_OVER(br, booked_rule)
        if ((br->predeclared) && (br->the_rule))
            WRITE("Constant BR_%d = %s;\n", br->allocation_id,
                ph_get_I6_representation(br->the_rule));
}
```

The function br_compile is called from 7/vasp.

The function br_resolve_predeclared_booked_rules is called from 12/cs.

§**7. Specificity of rules.** The following is one of NI's standardised comparison routines, which takes a pair of objects A, B and returns 1 if A makes a more specific description than B, 0 if they seem equally specific, or −1 if B makes a more specific description than A. This is transitive, and intended to be used in sorting algorithms.

```
int compare_specificity_of_br(booked_rule *br1, booked_rule *br2, int dflag) {
    phrase *ph1, *ph2;
    ph_runtime_context_data *rcd1 = NULL, *rcd2 = NULL;
    int rv;
    if ((br1 == NULL) || (br2 == NULL))
        internal_error("Compared specificity of null BR");
    if (dflag) {
        LOG("Comparing specificity of rules:\n(1) $b\n(2) $b\n", br1, br2);
    }
    ph1 = br1->the_rule;
    ph2 = br2->the_rule;
    if (ph1) rcd1 = &(ph1->runtime_context_data);
    if (ph2) rcd2 = &(ph2->runtime_context_data);
    rv = compare_specificity_of_phrcd(rcd1, rcd2);
    if (dflag) {
        if (rv != 0) {
            LOG("Decided by Law %s that ", c_s_stage_law);
```

```
        } else {
            LOG("Decided that ");
        }
        switch(rv) {
            case -1: LOG("(2) is more specific than (1)\n"); break;
            case 0: LOG("they are equally specific\n"); break;
            case 1: LOG("(1) is more specific than (2)\n"); break;
        }
    }
    return rv;
}
```

§8. Printing rule names at run time.

```
void br_compile_rule_printing_switch(OUTPUT_STREAM) {
    int j, k, cas; booked_rule *br; int brc=0;
    LOOP_OVER(br, booked_rule) {
        if (brc++ == 100000) internal_error("too many brs");
        j = -1; k = -1;
        if (br->word_ref1 >= 0) {
            [[j, k <-- br]];
            [[j, k == the ... --> j, k]];
        } else {
            if ((br->the_rule == NULL) ||
                (br->the_rule->declaration_node == NULL) ||
                (br->the_rule->declaration_node->down == NULL) ||
                (br->the_rule->declaration_node->down->word_ref1 < 0))
                continue;
        }
        WRITE("\t\tif (R == ");
        if (br->I6_value_of_rule[0])
            WRITE("%s", br->I6_value_of_rule);
        else
            WRITE("%s", ph_get_I6_representation(br->the_rule));
        WRITE(") { print \"");
        if (j >= 0) {
            print_raw_text_within_i6_literal(OUT, j, k); cas = 1;
        } else {
            if (br->the_rule->declaration_node) {
                [[j, k <-- br->the_rule->declaration_node]];
                [[j, k == the ... --> j, k]];
                print_raw_text_within_i6_literal(OUT, j, k);
                cas = 2;
            } else {
                if (br->I6_value_of_rule[0] != 0)
                    WRITE("%s", br->I6_value_of_rule);
                else
                    WRITE("%s", ph_get_I6_representation(br->the_rule));
                cas = 3;
            }
        }
        WRITE("\"; return; } ! %d, case %d\n", br->allocation_id, cas);
    }
```

```
}
```

The function br_compile_rule_printing_switch is called from 12/cs.

§**9. Lists of booked rules.** Booked rules are, in effect, two classes in one: the individual booked rules, and the linked list of an ordered sequence of the same. Methods dealing with lists of booked rules are distinguished by the `br_list` prefix.

BR lists are changed only by creation (naturally) and by the process of adding a rule to a BR list. The following invariants are preserved:

(a) The list head is a dummy BR which has never been the subject of any addition operation and has never moved.

(b) The only `FIRST_PLACEMENT` entries in the list immediately follow the list head. Those which were added explicitly as first-placed are in reverse order of addition to the list.

(c) The only `LAST_PLACEMENT` entries in the list are at the end. Those which were added explicitly as last-placed are in order of addition to the list.

(d) If R and S are middle-placed rules which were placed in the list within the same range (say, both anywhere, or both "after T" or "before U") and R precedes S, then either R is more specific than S, or they are equally specific and R was added to the list before S.

```
booked_rule *br_list_new(void) {
    return br_new(NULL);
}

int br_list_is_empty(booked_rule *list_head, scene *context) {
    booked_rule *br;
    if (list_head == NULL) return TRUE;
    br = list_head->next_rule;
    while (br) {
        if (context == NULL) return FALSE;
        if ((br->the_rule) &&
            (phrcd_get_scene(&(br->the_rule->runtime_context_data)) == context))
            return FALSE;
        br = br->next_rule;
    }
    return TRUE;
}

int br_list_is_empty_of_i7_rules(booked_rule *list_head) {
    booked_rule *br;
    if (list_head == NULL) return TRUE;
    br = list_head->next_rule;

The function br_list_contains_ph is called from 12/rb.

§**10.** When rule R is explicitly placed into (the rule list of) rulebook B (by an assertion like "R is listed after S in B", say), there are evidently two possibilities:

(i) R's phrase already occurs somewhere in rulebook B, so that this affects only the ordering of rulebook B. We therefore remove it (so that it does not occur twice in B) and reinsert it within the position range indicated. Note that this process still makes use of logical precedence; it simply confines itself to a narrower range. If R has to occur before S, then R is placed according to logical precedence within the sublist from the head of the list up to just-before-S.

To determine whether or not R's phrase is already in B, we compare their phrases if set, and their I6 equivalents if not. This will work on all non-declared BRs arising from phrases, and all BRs arising from named I6 library equivalents: it would however fail to recognise duplicates among predeclared BRs. However, it's impossible for these to arise in a way which permits duplication, so this does not matter.

Note that we search the entire rulebook for R, not just the valid interval in the rulebook where R might go (e.g., "after S").

(ii) R's phrase does not occur in B. We insert R into rulebook B within the position range indicated.

Each addition leaves the list either the same size or longer by 1.

If we insert a rule as first-placed rule when there already is a first-placed rule, the new one displaces it to go first, but both continue to be labelled as "first-placed", so that subsequent rule insertions of middle-placed rules will still go after both of them. Symmetrically, a second last-placed rule is inserted after any existing one, but both are labelled "last-placed". Because of the range possibility ("after S") we might find ourselves inserting a rule as middle-placed and yet still after a last-placed rule, or before a first-placed one: if so we change its placement to last or first respectively, in order to preserve invariants (b) and (c) above.

There was a small debate on `rec.arts.int-fiction` in February 2009 as to whether a rule placed instead of another rule within the same rulebook should be duplicated, or moved. In builds from 2008 and earlier,

there was duplication, but this broke the clean principle that a rule appears only once per rulebook, and made it difficult to place certain rules with tricky preambles; on the other hand merely moving makes it more difficult to replace a whole run of rules with a single place-holder. Both sides were argued for. In March 2009, it was finally decided to go with moving, not duplication, and to preserve the "only once per rulebook" principle.

```
void br_list_add(booked_rule *list_head, booked_rule *new_rule,
    int placing, int side, booked_rule *ref_rule) {
    booked_rule *pos, *prev, *end_rule, *start_rule, *subseq;

Rulebooks 12/rb

Purpose

To create, manage, compile and index rulebooks, the content of which is a linked list of booked rules together with some general conventions as to how they are to be used.

Template interpreter commands

```
4   {-array:rulebook_var_creators}
9   {-routine:RulebookOutcomePrintingRule}
10   {-callv:index_page_Rules}
```

Definitions

¶1. A rulebook consists of some general properties together with a linked list of booked rules, which constitute its entries. Some rulebooks are created explicitly by the user's source text, some are created explicitly by the Standard Rules, while others are "automatically generated" as a result of other creations by NI. For instance, each new scene ending generates a rulebook. There are numerous other examples because a rulebook is the natural and most flexible way to provide a "hook" by which to attach behaviour to a world model.

In some ways phrases and rules are really subsidiary ideas, and the rulebook is the fundamental level of programming in Inform 7. The reason it turns up so late in this chapter of definitions is that all of the other data structures were building up to this one: a `rulebook` contains `booked_rule`s which refer to `phrase`s whose usage is defined with `specification`s, and whose definition is stored in the `parse_node` tree until it can be resolved as a list of `invocation`s.

define `MAX_OUTCOMES_PER_RULEBOOK 10`

```
typedef struct rulebook {
    int word_ref1, word_ref2;                                   Name in source text
    int alt_word_ref1, alt_word_ref2;                           Alternative form of name
    int default_outcome_declared;                               flag: whether author has declared this
    int default_rule_outcome;                                   success, failure or none: see above
    int no_outcomes;
    int default_named_outcome;                                  alternative to the above
    struct rulebook_outcome named_outcomes[MAX_OUTCOMES_PER_RULEBOOK];
    int rulebook_focus;                                         always ACTION_FOCUS or PARAMETER_FOCUS
    int has_no_parameter;                                       if created as NO_FOCUS, this is set
    int rules_always_test_actor;                                for action-tied check, carry out, report
    int runs_during_activities;                                 allow "while..." clauses to name these
    int fragmentation_stem_length;                              0 for all ordinary rulebooks
    struct booked_rule *rule_list;                              linked list of booked rules
    struct placement_affecting *placement_list;                 linked list of explicit placements
    struct stacked_variable_owner *owned_by_rb;                 rulebook variables owned here
    struct stacked_variable_owner_list *accessible_from_rb;     and which can be named here
    char rb_I6_identifier[32];                                  I6 identifier name for array holding contents
    int used_by_future_action_activity;                         like "deciding the scope of something..."
```

```
    int automatically_generated;                    purely so that the index can omit these
    MEMORY_MANAGEMENT
} rulebook;
```

The structure rulebook is private to this section.

¶2. Placements:

```
typedef struct placement_affecting {
    struct parse_node *placement_sentence;
    struct placement_affecting *next;
    MEMORY_MANAGEMENT
} placement_affecting;
```

The structure placement_affecting is private to this section.

¶3. Each rulebook reaches one of three possible outcomes: success, failure and neither (meaning that it proceeded through to the end without any positive or negative news arising). If a rule does apply to the current circumstances (i.e., if the parameter is matched successfully) then it can explicitly choose to produce any of the three outcomes: if it makes no decision, the result is that stored in the rulebook's `default_rule_outcome` field. This is how

> Instead of going north, say "The snow is too deep."
>
> Before going north, say "Well, I'll try..."

behave differently: the instead rule halts the action, because the instead rulebook has a default outcome of `FAILURE_OUTCOME`; the before rule allows it to proceed, because the default is `NO_OUTCOME`.

```
define UNRECOGNISED_OUTCOME -1                      used in parsing only
define NO_OUTCOME 0
define SUCCESS_OUTCOME 1
define FAILURE_OUTCOME 2
```

¶4. However, a rulebook is allowed to give special problem-specific names to its outcomes.

```
typedef struct named_rulebook_outcome {
    int word_ref1, word_ref2;                       Name in source text
    MEMORY_MANAGEMENT
} named_rulebook_outcome;

typedef struct rulebook_outcome {
    struct named_rulebook_outcome *outcome_name;
    int kind_of_outcome;                            one of the three values above
} rulebook_outcome;
```

The structure named_rulebook_outcome is private to this section.
The structure rulebook_outcome is private to this section.

¶5. When a rulebook is being worked through at run-time, a special value or situation normally gives it a focus – something to work on. Rulebooks appear to the Inform user to come in three types:

(0) Action rulebooks, like "Instead of", which take a pattern match on the current action as their focus: for instance, the rule "Instead of eating something portable..." is in the "Instead of eating" rulebook but uses "something portable" as focus.

(1) Parametrised rulebooks, like "reaching inside", take (a pattern match on) a single parameter as their focus. For instance, "A rule for reaching inside the flask..." has the flask as focus.

(2) Rulebooks with no focus, like "turn sequence", are independent of circumstances.

In fact there are only really two types because rulebooks without focus (2) are internally converted to action rulebooks (0), but where the pattern matching is so broad that it matches every action. And in any case we set up the `action_pattern` structure in such a way that parametrised rulebooks (1) are handled almost exactly similarly to action ones as far as NI is concerned.

```
define ACTION_FOCUS 0
define PARAMETER_FOCUS 1
define NO_FOCUS 2
```

¶6. The following is used only to store the result of parsing text as a rulebook name:

```
typedef struct rulebook_match {
    struct rulebook *matched_rulebook;
    int match_length;
    int article_used;
    int placement_requested;
} rulebook_match;
```

The structure rulebook_match is shared with 12/phud.

¶7. The built-in rulebooks. As rulebooks are declared, the first few are quietly copied into a small array: that way, we can always obtain a pointer to, say, the turn sequence rules by looking up `built_in_rulebooks[TURN_SEQUENCE_RB]`. (These pointers are used only in the Rulebooks section.)

```
define MAX_BUILT_IN_RULEBOOKS 32

rulebook *built_in_rulebooks[MAX_BUILT_IN_RULEBOOKS];
struct stacked_variable_owner_list *all_action_processing_vars = NULL;
```

¶8. Many of the standard NI-created rulebooks need to have numbers which are predictable, because they need to be referred to by number by the I6 library code. Because of this, it is important not to change the numbers below without checking the corresponding I6 Constant declarations in the `Rulebooks.i6t` file: the two sets of declarations must exactly match. They must also exactly match the sequence in which these rulebooks are created in the Standard Rules file.

define PROCEDURAL_RB 0 — *Procedural rules*

§**1. Construction.** Whereas, at run-time, rulebooks are special cases of rules (they have the same kind of value, though their I6 values are such as to make it possible to distinguish them), within NI rulebooks and rules have entirely different data structures. There are two constructor functions: a basic one, used for those created by typical source text, and an advanced one used when rulebooks are automatically created as a result of other structures being built (for instance, scene endings).

```
rulebook *rb_new(int w1, int w2, int parametrisation) {
    rulebook *rb = CREATE(rulebook);
    [[w1, w2 == the ... --> w1, w2]];
    [[w1, w2 == ... rules --> w1, w2]];
    if [[w1, w2 == at ***]] {
        sentence_problem(_P_(C12RulebookWithAt),
            "this would create a rulebook whose name begins with 'at'",
            "which is forbidden since it would lead to ambiguities in "
            "the way people write rules. A rule beginning with 'At' "
            "is one which happens at a given time, whereas a rule "
            "belonging to a rulebook starts with the name of that "
            "rulebook, so a rulebook named 'at ...' would make such "
```

```
        "a rule inscrutable.");
}
if [[w1, w2 == definition ***]] {
    sentence_problem(_P_(C12RulebookWithDefinition),
        "this would create a rulebook whose name begins with 'definition'",
        "which is forbidden since it would lead to ambiguities in "
        "the way people write rules. A rule beginning with 'Definition' "
        "is one which defines an adjective, whereas a rule "
        "belonging to a rulebook starts with the name of that "
        "rulebook, so a rulebook named 'to ...' would make such "
        "a rule inscrutable.");
}
if [[w1, w2 == to ***]] {
    sentence_problem(_P_(C12RulebookWithTo),
        "this would create a rulebook whose name begins with 'to'",
        "which is forbidden since it would lead to ambiguities in "
        "the way people write rules. A rule beginning with 'To' "
        "is one which defines a phrase, whereas a rule "
        "belonging to a rulebook starts with the name of that "
        "rulebook, so a rulebook named 'to ...' would make such "
        "a rule inscrutable.");

    if (code >= 0) t += rb_index(built_in_rulebooks[code], desc, NULL, an);
    if (rb) t += rb_index(rb, desc, NULL, NULL);
    br_list_resume_indexed_links();
    if (t > 0) INDEX("<br>");
}
```

The function rb_log_name_only is called from 12/phud.
The function log_rulebook is called from 2/dl.
The function rb_index is called from 9/tmap and 11/av.
The function rb_index_action_rules is called from 11/act.

§**6. Name parsing of rulebooks.** Now we parse the names of rulebooks. The obvious way, using the main excerpt parser, is all very well: but it doesn't contain nearly enough variation for rulebook name clauses used in phrase headers, and a special routine is used for these.

```
rulebook *rb_by_name(int w1, int w2) {
    meaning_list *ml;
    [[w1, w2 == the ... --> w1, w2]];
    ml = SP_excerpt(RULEBOOK_MC, w1, w2);
    if (ml) return RETRIEVE_POINTER_rulebook(em_data(ml_meaning(ml)));
    return NULL;
}

rulebook_match rb_match_from_description(int w1, int w2) {
    int initial_w1 = w1, modifier_words;
    int art = NO_ART, pl = MIDDLE_PLACEMENT;
    rulebook *rb;
    rulebook_match rm;
    if [[w1, w2 == a/an ... --> w1, w2]] art = INDEF_ART;
    else if [[w1, w2 == the ... --> w1, w2]] art = DEF_ART;
    if [[w1, w2 == rule ... --> w1, w2]] {
        [[w1, w2 == for/about/on ... --> w1, w2]];
    } else {
        if [[w1, w2 == first ... --> w1, w2]] pl = FIRST_PLACEMENT;
        else if [[w1, w2 == last ... --> w1, w2]] pl = LAST_PLACEMENT;
    }
    modifier_words = w1 - initial_w1;
    rm.match_length = 0;
    rm.matched_rulebook = NULL;
    rm.article_used = art;
    rm.placement_requested = pl;
    LOOP_OVER(rb, rulebook) {
        int x1 = rb->word_ref1, x2 = rb->word_ref2;
        if ((rb->has_no_parameter) && (w2-w1 != x2-x1)) goto TryAlt;
        if (w2-w1 >= x2-x1) {
            int this_match = x2-x1+1;
            if (compare_word_range(x1, x2, w1, w1+x2-x1) == FALSE) goto TryAlt;
            if (rm.match_length < this_match) {
                rm.match_length = this_match;
                rm.matched_rulebook = rb;
            }
        }
        TryAlt: x1 = rb->alt_word_ref1; x2 = rb->alt_word_ref2;
        if (x1 < 0) continue;
        if ((rb->has_no_parameter) && (w2-w1 != x2-x1)) continue;
        if (w2-w1 >= x2-x1) {
            int this_match = x2-x1+1;
            if (compare_word_range(x1, x2, w1, w1+x2-x1) == FALSE) continue;
            if (rm.match_length < this_match) {
                rm.match_length = this_match;
                rm.matched_rulebook = rb;
            }
        }
    }
```

```
    if (rm.match_length == 0) return rm;
    if (rm.matched_rulebook->fragmentation_stem_length) {
        int w1a = w1 + rm.match_length - 1;
        if (w1a != w2) {
            rm.match_length = rm.matched_rulebook->fragmentation_stem_length;
            w1a = w1 + rm.match_length - 1;
        }
    }
    rm.match_length += modifier_words;
    return rm;
}
```

The function rb_by_name is called from 12/rps.
The function rb_match_from_description is called from 12/phud.

§**7. Rule attachments.** The following routine contains a bit of a surprise: that the act of placing a BR within a given rulebook can change it, by altering the way it acts on its applicability test. This is a device needed to manage the parallel rulebooks for action processing for the main player character and for third parties. Though the code below does not make this apparent, the changes propagate down through the BR to the phrase structure itself. This is necessary because they manifest themselves in the compiled code of the phrase, but it is also unfortunate, because it is possible that the same phrase is used by more than one BR. If it should happen that BRs are created to place the same phrase into two different rulebooks, therefore, and which have different actor-testing settings, the outcome would be confusing. (As unlikely as this seems, it did once happen to a user in beta-testing.)

All work on the sequence of rules in rulebooks is delegated to the sub-section on linked lists of booked rules in the section on Rules.

```
void rb_attach_rule(rulebook *rb, booked_rule *the_new_rule,
    int placing, int side, booked_rule *ref_rule) {
    LOGIF(RULE_ATTACHMENTS, "Attaching booked rule $b at sentence:\n  $T",
        the_new_rule, current_sentence);
    LOGIF(RULE_ATTACHMENTS, "Rulebook before attachment: $K", rb);
    if (ref_rule) {
        LOGIF(RULE_ATTACHMENTS, "With respect to $b\n", ref_rule);
    }
    if (rb == built_in_rulebooks[SETTING_ACTION_VARIABLES_RB]) {
        br_set_never_test_actor(the_new_rule);
    } else {
        if (rb->rules_always_test_actor) {
            LOGIF(RULE_ATTACHMENTS,
                "Setting always test actor for destination rulebook\n");
            br_set_always_test_actor(the_new_rule);
        }
        if (rb->rulebook_focus == PARAMETER_FOCUS){
            LOGIF(RULE_ATTACHMENTS,
                "Setting never test actor for destination rulebook\n");
            br_set_never_test_actor(the_new_rule);
        }
    }

The function rb_detach_rule is called from 12/rps.

§**8. Compilation.** We do not actually compile the I6 routines for a rulebook here, but simply act as a proxy. The I6 arrays making the rulebooks available to run-time code are the real outcome of the code in this section.

```
void rb_compile_rule_phrases(rulebook *rb, OUTPUT_STREAM, int *i, int max_i) {
    br_list_judge_ordering(rb->rule_list);
    if (br_list_is_empty_of_i7_rules(rb->rule_list)) return;
    WRITE("\n");
    compile_i6_divider_comment(OUT);
    WRITE("! Rules in rulebook: ");
    print_raw_text_within_i6_literal(OUT, rb->word_ref1, rb->word_ref2);
    WRITE(" (%s)\n", rb->rb_I6_identifier);
    compile_i6_divider_comment(OUT);
    br_list_compile_rule_phrases(rb->rule_list, OUT, i, max_i);
    compile_i6_divider_comment(OUT);
}
void rb_compile_rulebooks_array_array(OUTPUT_STREAM) {
    rulebook *rb;
    WRITE("Array rulebooks_array -->");
    LOOP_OVER(rb, rulebook)
        WRITE(" %s", rb->rb_I6_identifier);
    WRITE(" 0;\n");
}
void rb_compile_rulebooks(OUTPUT_STREAM) {
    rulebook *rb;
    LOOP_OVER(rb, rulebook) {
        LOGIF(COMPILE_RULEBOOKS, "Compiling rulebook: $W = %s\n",
            rb->word_ref1, rb->word_ref2, rb->rb_I6_identifier);
        br_list_compile(rb->rule_list, OUT, rb->rb_I6_identifier);
    }
```

```
}
void rb_compile_RulebookNames_array(OUTPUT_STREAM) {

13 Grammar

13/igr: *Introduction to Grammar.w* An exposition of the data structures and basic method used to deal with the command-parsing grammar implied by Understand sentences in the source text.

13/tfg: *Traverse for Grammar.w* To create and manipulate grammar, primarily by parsing and acting upon Understand... sentences in the source text.

13/gv: *Grammar Verbs.w* A grammar verb is not literally a verb, as the name is a hangover from the way I6 defines grammar. It might be said to be a necklace onto which we thread the sea-shells of grammar lines. Each grammar verb has its own purpose: to match various possibilities (one for each grammar line) against text aimed at a particular result. For instance, all run time commands beginning with TAKE are parsed with a single grammar verb. If we create a new grammar token, "[polite remark]", for use in other grammar, then that too will have its own "grammar verb". If we define the word "eleventy-one" as meaning the number 111, it will be added to a grammar verb attached to the data type `NUMBER` which parses eccentric names for number values. And so on. Probably a better name for this structure would be simply "grammar", but that might be confusing in other ways, and anyway the ship has sailed.

13/gl: *Grammar Lines.w* A grammar line is a list of tokens to specify a textual pattern. For example, the NI source for a grammar line might be `"take [something] out"`, which is a sequence of three tokens.

13/gty: *Grammar Types.w* Some grammar text specifies one or more values, and we need to keep track of their data type(s). Here we manage the data structure doing this.

13/gtok: *Grammar Tokens.w* To handle grammar at the level of individual tokens. I7 grammar tokens correspond in a 1-to-1 way with I6 tokens: here we determine the I7 type a token represents (if any) and compile it to its I6 grammar token equivalent as needed.

13/nft: *Noun Filter Tokens.w* Filters are used to require nouns to have specific kinds or attributes, or to have specific scoping rules: they correspond to Inform 6's `noun=Routine` and `scope=Routine` tokens. Though these are quite different concepts in I6, their common handling seems natural in I7.

13/gprv: *Tokens Parsing Values.w* In the argot of Inform 6, GPR stands for General Parsing Routine, and I7 makes heavy use of GPR tokens to achieve its ends. This section is where the necessary I6 routines are compiled.

13/gpr: *General Parsing Routines.w* To compile I6 general parsing routines (GPRs) and/or `parse_name` properties as required by the I7 grammar.

13/test: *Test Scripts.w* A rudimentary but useful testing system built in to IF produced by Inform, allowing short sequences of commands to be concisely noted in the source text and tried out in the Inform application using the TEST command.

Introduction to Grammar 13/igr

Purpose

An exposition of the data structures and basic method used to deal with the command-parsing grammar implied by Understand sentences in the source text.

§**1.** This is grammar in the sense of the parsing structures used at run-time, and it occupies a chapter of its own in the source code since it is to some extent detached from the rest of NI: what we create in this chapter is almost an independent compiler in its own right, but of a much simpler language. Although we use many higher-level features of NI in the process, none use this.

Grammar is organised in a three-level hierarchy:

(a) A grammar verb (GV) is a small independent grammar of alternative formulations for some concept: for instance, the possible commands beginning TAKE, or the possible verbal forms of numbers. Each GV is a list of GLs, and an individual GL must belong to exactly one GV. There are five different types of GV, differentiated mostly by the purpose to which the GV is put:
   1. `GV_IS_COMMAND`. An imperative verbal command at run-time.
   2. `GV_IS_TOKEN`. A square-bracketed token in other grammar.
   3. `GV_IS_OBJECT`. A noun phrase at run time: a name for an object.
   4. `GV_IS_VALUE`. A noun phrase at run time: a name for a value.
   5. `GV_IS_CONSULT`. A pattern to match in part of a command (such as "consult").
   6. `GV_IS_PROPERTY_NAME`. A noun phrase at run time: a name for one possibility for an either/or property, say "open" or "fixed in place".

(b) A grammar line (GL) is a single possibility within a GV: for example, the line matching `"take [something]"` in the GV for the TAKE command. Each GL is a list of tokens, and an individual token must belong to exactly one GL.

(c) A grammar token (GTOK) is a single particle of a GL: for example, `'take'` and `something` are tokens.

The picture is not quite so hierarchical as it looks, though, because a GV naming a token can be used as a token inside other GVs. We need to be careful that this does not lead to infinite regress: see below.

Much of what we do with grammar involves recursing down this hierarchy, in some cases allowing results to percolate back upwards. What happens takes place in four chronological phases. (This division into phases is convenient because Inform 6 requires that all general parsing routines and noun filter routines already exist when a `Verb` directive is reached which uses them.)

§**2. Phase I: Slash Grammar.** Slashing is the process of dealing with slashes `/` used in grammar to indicate alternatives.

§**3. Phase II: Determining Grammar.** We check that the grammar is well-founded and find the types of values expressed by it, if any.

Determining well-foundedness means checking that no two grammar tokens each require the use of the other, and that when a grammar token takes several alternative forms, they have compatible results: so, for instance, you can't have one version resulting in a number and another in a thing. (This check is only meaningful for grammar verbs of type `GV_IS_TOKEN`.)

The result of a `GV_IS_TOKEN` is a single type, which is the union of the types resulting from its grammar lines. This is a more sophisticated approach than we really need here, but we may as well use the type-casting machinery for the sake of any later expansion (if kinds of kinds of value are ever allowed, for instance).

Of the determining traverse the following can be said:

(a) either errors are produced, or it is verified that no token's definition depends directly or indirectly on already knowing itself;

(b) also that no grammar line attached to a `GV_IS_COMMAND` produces more than 2 values, and that no grammar line attached to anything else produces more than one; and

(c) also that the grammar lines attached to a `GV_IS_TOKEN` are compatible in that there is a type to which they can all always be cast.

We note of the determining routines that:

(a) `gv_determine` runs at least once for each GV;

(b) `gl_determine` runs exactly once on each GL;

(c) `gtok_determine` runs exactly once on each token.

§**4. Phase III: Sort Grammar.** We must ensure that if grammar line L1 is logically impossible once L2 has been parsed, then L1 must be checked before L2, regardless of the ordering in the source code. Since the data sets are very small and time is not of the essence, we simply insertion-sort the original definition-order list into a second linked list.

§**5. Phase IV: Compile Grammar.** The final run-through, which uses the sorted order and not the original declaration order, actually compiles the necessary I6 `Verb` and `Extend` directives.

Traverse for Grammar 13/tfg

Purpose

To create and manipulate grammar, primarily by parsing and acting upon Understand... sentences in the source text.

13/tfg.§4 Dividing Understand into cases; §5 Understand command verbs; §6 Understand property names; §7 Understand the player's command or snippets

---

Template interpreter commands

```
2   {-callv:traverse_for_grammar}
```

---

§**1.** New grammar arrives in the system in two ways: primarily by means of explicit Understand sentences in the source text, but also secondarily in the form of table entries or other values used to match against snippets. For example:

> Understand "drill [something]" as drilling.
>
> if the player's command matches "room [number]", ...

§**2.** Understand sentences can also revoke existing grammar, in some cases, as we shall see. They are not read in the main assertion traverse, since they depend on too much not known then: they have a traverse of their own, and so do not use the sentence handler system adopted by the main assertion traverse.

```
int base_problem_count;
void traverse_for_grammar(void) {
    int w1, w2, as1, as2, when1, when2, w;
    parse_node *p;
    for (TREE_START(p); p; TREE_NEXT(p))
        if (pn_get_node_type(p) == SENTENCE_NT) {
            if ((p->down)
                && (pn_get_node_type(p->down) == VERB_NT)
                && (pn_int_annotation(p->down, verb_id_ANNOT) == UNDERSTAND_VB)) {
                [[w1, w2 <-- p->down->next]];
                [[as1, as2 <-- p->down->next->next]];
                when1 = -1; when2 = -1;
                if (![[as1, as2 == ... when ... : w --> as1, as2 ... when1, when2]])
                    [[as1, as2 == ... while ... : w --> as1, as2 ... when1, when2]];
                base_problem_count = problem_count;
                understand_sentence(w1+1, w2, as1, as2, when1, when2);
                finish_this_session_of_parsing();
            }
        }
}
```

The function traverse_for_grammar is invoked by a command in a `.i6t` template file.

§**3.** The secondary means of acquiring new grammar is used when compiling type specifications of type `VALUE/UNDERSTANDING` and when compiling the entries of "topic" columns in tables. These will usually be simple constructions of individual grammar lines, but they need to belong to a grammar verb (GV) nevertheless, even if they are the only thing on that GV. Such GVs compile to routines for parsing snippets, and no pointers exist to them in other NI data structures: the result of the routine below, assuming no problems are issued, is simply that the name of a snippet-parsing routine is printed.

```
void compile_understanding(OUTPUT_STREAM, int w1, int w2, int table_entry) {
    if [[w1, w2 == it]] WRITE("0");
    else {
        base_problem_count = problem_count;
        gpr_prepare_consultation_gv();
        understand_block(w1, w2, -1, -1, -1, -1, table_entry);
        gpr_print_consultation_gv_name(OUT);
    }
}
```

The function compile_understanding is called from 7/vasp and 10/tab.

§**4. Dividing Understand into cases.** There are three basic cases, according to what must be understood: the player's command (tacitly assumed), a command verb or a property name.

```
void understand_sentence(int w1, int w2, int as1, int as2, int when1, int when2) {
    LOGIF(GRAMMAR, "Parsing understand <$W> as <$W> when <$W>\n",
        w1, w2, as1, as2, when1, when2);
    if (problem_count > base_problem_count) return;
    if [[w1, w2 == the command/commands ... --> w1, w2]] {
        understand_the_command(w1, w2, as1, as2, when1, when2);
        return;
    }
    if [[w1, w2 == the verb/verbs ...]] {
        sentence_problem(_P_(C13OldVerbUsage),
            "this is an outdated form of words",
            "and Inform now prefers 'Understand the command ...' "
            "rather than 'Understand the verb ...'. (Since this "
            "change was made in beta-testing, quite a few old "
            "source texts still use the old form: the authors "
            "of Inform apologise for any nuisance incurred.)");
        return;
    }
    if (is_list_divided(w1, w2, LOOK_FOR_AND + LOOK_FOR_OR)) {
        int lw1 = left_w1, lw2 = left_w2, rw1 = right_w1, rw2 = right_w2;
        understand_sentence(lw1, lw2, as1, as2, when1, when2);
        understand_sentence(rw1, rw2, as1, as2, when1, when2);
        return;
    }
    if [[w1, w2 == ... property --> w1, w2]] {
        understand_property_block(w1, w2, as1, as2, when1, when2);
        return;
    }
    understand_block(w1, w2, as1, as2, when1, when2, FALSE);
}
```

§**5. Understand command verbs.** These sentences allow us to control the assignment of command verbs such as TAKE or EXAMINE to grammars, which will normally be an automatic process based on grammar lines (see below). We can make one command verb an alias for another, or revoke this by making it "something new".

After some debate, we decided that it ought to be legal to declare "Understand the command "wibble" as something new" even in cases where no "wibble" command existed already: extensions might want this to assure that they have exclusive use of a command, for instance. So the problem message for this case is now commented out.

```
void understand_the_command(int w1, int w2, int as1, int as2, int when1, int when2) {
    grammar_verb *gv;
    if (problem_count > base_problem_count) return;
    if (when1 >= 0) {
        sentence_problem(_P_(C13UnderstandCommandWhen),
            "'understand the command ... as ...' is not allowed to have a "
            "'... when ...' clause",
            "for the moment at any rate.");
        return;
    }
    if (is_list_divided(w1, w2,
        LOOK_FOR_OR+LOOK_FOR_AND)) {
        int lw1 = left_w1, lw2 = left_w2, rw1 = right_w1, rw2 = right_w2;
        understand_the_command(lw1, lw2, as1, as2, when1, when2);
        understand_the_command(rw1, rw2, as1, as2, when1, when2);
        return;
    }
    dequote_word(w2);
    gv = gv_find_command(w2);
